THE patentee cuts the wood at an angle across the grain into slices 3mm. thick, which are removed from the cutting machine by a blower which granulates the wood and drives it through a tube to a series of bins, from which it can be dropped into tanks. These, which may be from ten to twenty in number, are made with false bottoms and provided overhead with sprinklers. In these the wood is placed and extracted by percolation, the liquor from the first tank being pumped over the next, and so on, till in the last it percolates through fresh wood and passes away, of maximum strength. The water used is at a temperature of 90°, and a small percentage of sulphuric or hydrochloric acid is added, either to the fresh water or by sprinkling in one of the tanks. One tank is continuously out of use whilst being emptied of refuse and refilled, and when the first tank is exhausted comes into use as the strongest of the series. The liquor is next neutralised by an alkaline solution of casein (one part carbonate of soda to fifty parts casein), which is thus precipitated as a fine flocculent precipitate carrying down with it the impurities. It is next forced through a filter press and evaporated in vacuo to 25 or 30°. Any similar clarifying agent may replace the casein—*e.g.*, albumen.—R. L. W.

An Improved Leather Polish. J. H. G. Langenhagen, Leipsic, Germany. Eng. Pat. 17,026, Dec 29, 1886. 4d.

Mineral fats or mixtures of mineral fats and wax, being little absorbed by leather, whilst vegetable and animal fats turn rancid, the patentee proposes the following mixture, the speciality of which is the use of oil of turpentine to secure absorption and preserve gloss:—40 per cent. Carnauba wax, 1 per cent. steatite, 30 per cent. oil of turpentine, 5 per cent. aniline (nigrosine), 2 per cent. Congo-black, 8 per cent. almond oil, 4 per cent. beeswax and 10 per cent. ozokerit.—R. L. W.

XIV.—AGRICULTURE, MANURES, Etc.

Treating Barley with Sulphurous Acid. H. Eckenroth. Chem. Zeit. **11**, 110.

When old barley is treated with sulphurous acid it assumes a fine yellow colour, and can be mistaken for new barley. Such treatment is injurious to the germinating power, but has recently been practised to a considerable extent in Germany, inasmuch as 60 per cent. of the samples examined contained sulphur. They were tested by steeping the barley for a quarter of an hour in hot water, and adding zinc and hydrochloric acid to the aqueous extract, the presence of sulphur being soon indicated by the evolution of hydrogen sulphide.

—D. A. L.

Value of Superphosphate for Sugar-Beet. A. Nautier, Bied. Centr. **15**, 742—744.

These experiments were instituted to investigate the value of manuring with superphosphate on certain soils. On a soil containing per cent.:—P_2O_5, 0·34; N, 0·17: K_2O, 0·53, and which had received a dressing of 35,000 kilos. of farmyard manure per hectare in the autumn, eleven plots were arranged; one remained unmanured, three received 75kilos. of nitrogen per hectare, in the form of Chili saltpetre, ammonium sulphate, and oil-cake respectively. On six other plots the same series of nitrogenous manures was twice repeated; once with addition of 75kilos., and once with 150kilos. of soluble phosphoric acid per hectare. The eleventh plot received phospho-guano equivalent to 75kilos. of soluble organic nitrogen and 75kilos. soluble phosphoric acid per hectare. An increase in the weight of crop was obtained with the phospho-guano on all the nitrate of soda plots and also on the ammonium sulphate plots, except where the 150kilos. of phosphoric acid was used in addition. On the other hand, the quality of the roots as regards sugar was so poor that only in one case (where nitrate of soda had been used alone) did the increase in value even cover the cost of the manure. The superphosphate, in fact, proved valueless in these experiments. Experiments on a poorer soil containing per cent:—P_2O_5, 0·08; N, 0·17; K_2O, 0·42, gave different results, for in all cases phosphoric acid, either as soluble, citrate soluble, or insoluble, although it did not give such heavy crops as in the above experiments, improved the quality to such an extent as to more than cover the cost of manure. For example—with 75kilos. of phosphoric acid per hectare as superphosphate the gain was 64·2 francs, with 75kilos. as natural insoluble phosphate 81·0 francs, and with 225kilos. as natural insoluble phosphate, the quantity equivalent in money value to the 75kilos. of phosphoric acid as superphosphate, the gain was 49·0 francs.

—D. A. L.

Manurial Experiments with Basic Slag and other Phosphates on Rye Crops. M. Sievert. Bied. Centr. **15**, 744—745.

Four plots of equal extent were manured with 30 pounds per morgen (0·255 hectare) of phosphoric acid in four different forms and 10½ pounds per morgen of nitrogen as ammonium sulphate, or in the case of bone-meal the nitrogen already present was made up to 10½ pounds with ammonium sulphate. Comparing the harvest results, and taking the yield from basic slag at 100, bone-meal yielded 111·06, superphosphate 120·09, curacao-phosphate 113·04. The profit per mark outlay for this increase in crop was in the case of bone-meal 3·6 marks, of superphosphate 3·2 marks, of curacao-phosphate 6·2 marks.—D. A. L.

Losses in Wheat Cultivation by the injudicious use of Copper Sulphate as a Preventative against Mildew. P. Grassman. Bied. Centr. **15**, 766—774.

To prevent mildew in wheat, it is customary to treat the seed with copper sulphate. Kühn has given directions for the application of this salt, but in practice, in spite of these directions, the quantities of sulphate employed and the mode of treatment, vary considerably; consequently the success of the treatment, in many cases, becomes very questionable. The author has taken the matter in hand, and from the standpoint that the object in view is the destruction of the mildew fungus without injury to the vitality of the wheat, has investigated the effect of the strength of copper sulphate solution employed and the result of delay in sowing after the seed has been treated:—1. On the germinating energy or rate of germination. 2. On the germinating power or total proportion of germinating seeds. 3. On the proportion of sickly seedlings. And it is seen that any increase in strength of the solution, or any delay in time of sowing the treated seed, weakens the germinating energy, decreases the number of germinating seeds and increases the proportion of sickly seedlings (rootless or with diseased roots). Even with one pound of copper sulphate to 30 centners of seed wheat (one centner = 100 pounds), the germinating energy is reduced 2·25 per cent., and the sickly seedlings increase 0·25 per cent.; with 20 pounds to 20 centners, the germinating energy is nil, whilst all seedlings are sickly. It is, therefore, recommended not to use more than three pounds of copper sulphate per 20 centners of seed grain, and to allow the grain to soak from 12 to 16 hours, removing any floating grains, as diseased grains are always light; finally, to sow the macerated seed without much delay; if possible, within 24 hours.—D. A. L.

Development of the Sugar-beet. A. Girard. Compt. Rend. **102**, 1324—1327, 1489—1492, 1565—1567; **103**, 72—74, 159—162.

Numerous observations have been made on the development of the different parts of the sugar-beet plant, and of the composition of the plants at various stages of growth during the period of moist active vegetation. A table is given, showing the relation the weights of the leaves, stem, root and rootlet, to the weight of the whole plant at the various stages of growth. On June 8 the proportion per cent. was:—Leaves, 83·1; stem, 6·8; roots, 10·1; then follows a period when the proportion of the roots decreases, whilst the leaves increase considerably, and the stem steadily, so that on July 15, the leaves form 68·5, the stem 29·5, and the roots and rootlets, 2·0 per cent. During the last two months, the weight of roots and rootlets, and of the leaves, increases only very slightly, especially the latter, whilst the stem increases considerably, hence on October 1, the proportion stands: leaves, 35·2; stem, 63·3; roots and rootlets, 1·5. Under normal meteorological conditions, however, the increase of these various parts and also of their various constituents (woody fibre, soluble organic and mineral matters) is generally regular. But under certain climatic conditions, the roots become quickly woody, and then this is accompanied by a rapid increase in the weight of the stem and considerable fluctuation in the quantity of sugar in the leaves, although the sugar already stored does not decrease. From the earliest stages, the sugar-beet plant contains sugar: even when it weighs scarcely 1grm. it contains 1·5 per cent., and during active growth, under the influence of sunlight, sugar forms in the leaves, passing through the stem to the root, while mineral matters and water taken from the soil by the rootlets, travel up the stem to the leaves.—D. A. L.

An Improved Process of Treating Phosphatic Earths and Rocks for the Manufacture of Fertilisers therefrom. N. B. Powton, Kingston, Jamaica. Eng. Pat. 5034, April 10, 1886. 6d.

PHOSPHATIC MINERALS, which are mainly composed of phosphates of iron and alumina, have thus far not been successfully worked up as superphosphates, owing to the fact that the product of the treatment with sulphuric acid remained in a sticky, gummy state, which would not dry, and could not be ground. This process converts the alumina into alum, and combines the phosphoric acid with lime, whereby the mass is rendered dry and granular. The mode of proceeding is as follows:—The ground mineral is mixed with water, and an alkaline base, such as soda, potash or lime. Sulphuric acid is then added, and the mass stirred for some time. After thoroughly mixing, the mass is poured out, when it will dry naturally, and granulate in a fine powder, owing to the formation of an alum and calcium sulphate, both of which combine chemically with the water present in the fertiliser.
—S. H.

XV.—SUGAR, GUMS, STARCHES, Etc.

Extraction of Sugar Cane by means of Diffusion. Dingl. Polyt. J. **262**, 478—479.

THIS paper is an extract from a report on methods and machinery for the application of diffusion to the extraction of sugar cane, by H. W. Wiley, who has recently inspected several sugar works in France and Spain for the United States Government. The beet diffusion works at Abbéville in France, being regarded as one of the best of the kind, are described in detail in the report, which is illustrated by a number of useful diagrams of the plant and machinery employed. With regard to cutting-machines, it is shown that the best results are obtained with cane chips, which are from 2 to 3mm. in thickness, being at the same time nicely grooved. This is done by adjusting the edges of the knives in a certain manner. At the works at Almeria, the diffusion battery consists of 14 vessels, each vessel holding 25 hectolitres and containing a charge of 1215kilos. of cane chips. From these 13·5 hectolitres of juice are obtained, or 111 litres from 100 kilos. of canes. During the diffusion process, a temperature of 80—90° is maintained in all the vessels, which is said to facilitate the extraction, without injuring the colour of the juice. The exhausted chips are exposed to the atmosphere until putrefaction sets in. They are then used for manuring purposes. To use them as fuel would necessitate partial drying. Experiments have shown that almost all the sugar present in the sugar cane can be readily extracted by diffusion. With a properly constructed cutting machine and a sufficient number of vessels, the treated chips should not contain more than 0·1 to 0·2 per cent. of sugar, whilst the crushed cane, from which the juice has been extracted by pressure, contains about 3·63 per cent. of sugar. At Tore del Mar the juice is expressed from the canes, and the bagasse subjected to diffusion. The exhausted bagasse is placed into manure pits one metre in depth and then made up in heaps two metres above the surface of the ground, and covered with earth and the refuse from a distillery in connection with these works. After a year a valuable manure is obtained, which is sold to farmers.—D. B.

The Applicability of Condensed Steam from Sugar Works for Steam-boiler Purposes. C. Stammer. Dingl. Polyt. J. **263**, 189—193.

DR. CLAASSEN (*Deutsche Zuckerindustrie*, 1886, No. 10) expressed his opinion that the presence of sugar in water used for feeding steam-boilers caused corrosions of the boiler plates, owing to the formation of fatty acids as products of the decomposition of the sugar. He collected a brown powder from a boiler of a sugar works, that was fed with condensed steam, and found it to contain 11 per cent. organic matter, 6 per cent. of which were of an acid nature. The acid had entered into combination with iron. Without examining these organic acids any further, Claassen concluded that they were products of decomposition derived from the sugar, although a direct test of the feed-water with Fehling's solution showed the absence of sugar. Stammer cannot but condemn results which were obtained in this unscientific manner. He does not deny the corrosion, but thinks that the acids were more likely fatty acids which found their way into the boiler from the lubricators used for the steam cylinder, packing, and so forth. If condensed steam could be kept free from fatty matter, it is certainly the best kind of water for steam boiler purposes, but as fatty matter is only too likely to be carried into the boiler, a counteracting agent must be introduced along with it, in order to avoid injury to the plates. The addition of sodium carbonate, lime or lime water can be highly recommended as cheap and effective. The author does not contend the possibility that sugar or its products of decomposition may be injurious to boiler plates, but he thinks it rash to blame sugar for corrosions if it cannot even be detected in the feed-water.—S. H.

Improvements in the Manufacture of Caramel. C. W. N. Wallace, Southwark, and C. J. H. Barry, Camberwell. Eng. Pat. 4679, April 3, 1886. 4d.

THESE consist in heating a mixture of sugar and dilute acid at about 200° F. for some hours, adding a slight excess of sodium carbonate, and evaporating to the required consistency.—G. H. M.

XVI.—BREWING, WINES, SPIRITS, Etc.

Studies on Diastase. C. H. Lintner. J. Prakt. Chem. **34**, 1886, 378—394.

THE author has endeavoured to isolate pure diastase. The various methods used for preparing it were accompanied by a quantitative determination of the efficiency of the diastase obtained, as the degree of sacharification must be looked upon as an important criterion, both of the value of the method and of the purity of the substance. To determine the efficiency of the diastase, Kjedahl uses starch made soluble by extract of malt at 50°. The author, however, finds that this solution gives no reliable results, and replaces the malt by hydrochloric acid. In order to obtain 100cc. of the test solution, 2grms. air-dried potato starch are weighed into a bottle, mixed with 10cc. of a $\frac{1}{10}$th p.c. hydrochloric acid solution, and about 60cc. water, and the corked bottle heated at 100° in the water-bath. After the lapse of half-an-hour the starch dissolves, and though the solution is opalescent, it is perfectly mobile and hardly reduces Fehling's solution, thus comparing favourably with Kjedahl's starch solution. The acid is exactly neutralised with 10cc. of a $\frac{1}{10}$th per cent. caustic soda solution, and the solution made up to 100cc. If a large number of determinations is to be made, it is advisable to prepare large quantities of soluble starch, and weigh off the amount required in each case. To this end, a certain quantity of best potato starch is mixed with hydrochloric acid of 7·5 per cent. strength, so that the acid layer covers the starch. After standing seven days at the ordinary temperature of the air, or three days at 40°, the starch loses its power of forming a paste. It is washed by decantation with cold water until absolutely freed from acid, the water drawn off completely, and the residue dried. This starch is easily soluble to a clear fluid in hot water. Two per cent. solutions remain clear or slightly opalescent for several days. Concentrated (10 per cent.) solutions gelatinise on cooling. Fehling's solution is hardly reduced. To determine the diastatic action of malt, 25grms. of finely-powdered cured malt or well-macerated green malt are brought on a filter and extracted with 500cc. water, and the filtrate cleared by pouring back three or four times on to the filter. Into each one of 10 test tubes 10cc. of the test solution—viz., 2grms. starch in 100cc. water—are introduced, and into each consecutive test tube 0·1, 0·2, 0·3, etc., to 1·0cc. extract of malt solution are respectively added; the diastase is allowed to act for one hour. 5cc. Fehling's solution are now brought into each test tube, all of which are then placed in boiling water for 10 minutes. The tube in which all cupric oxide has just been reduced is then selected, and the diastatic value of the above extract determined; the fermentative power of a malt extract may be taken at 100, when, under the above circumstances, 0·1cc. of an extract of 25grms. malt with 500cc. water reduces 5cc. Fehling's solution.

Preparation of Diastase.—Green malt from barley is most suitable for obtaining diastase. Air-dried malt may also be used. Cured malt is not practicable. The author recommends the following as the best method of preparing diastase:—1 part green malt from barley or sifted air-dried malt is treated with 2—4 parts of 20 per cent. alcohol for at least 24 hours; the extract in the filtrate is precipitated by adding 2—2½ times the volume of absolute alcohol; the diastase is quickly filtered, macerated with absolute alcohol, again filtered and washed with the latter, then macerated with absolute ether, and after filtering dried in vacuo over sulphuric acid. After thoroughly drying the diastase in this manner, it is obtained as a loose yellowish-white powder of great efficiency. Before using, it must be well macerated with a little water. To prepare *pure* diastase the latter raw product is dissolved in water, precipitated and allowed to stand some time with alcohol, when it is washed with ether and dried, this process being repeated several times, in order to render the albuminous substance insoluble. Inorganic substances adhere most persistently to diastase; even after six precipitations, there were still 10 per cent. of the former, consisting chiefly of neutral calcium phosphate. Five per cent. were removed by dialysis; the remaining five consisted of pure calcium phosphate. Certain interesting relations existing between the quantity of nitrogen and the diastasic action of various substances are given.

The author, contrary to Payen and Persoz, shows diastase to be a nitrogenous body. No higher percentage than 10·4 (calculated on substance free of ash) is it possible to reach by purifying the ordinary diastase. An analysis gave numbers which show that the composition of diastase differs considerably from that of the albuminous substances (C=46·66, H=7·35, N=10·41, and S=1·12 per cent. respectively) (calculated on the substance free from ash). But the composition is similar to that of other ferments, such as pancreatic ferments, invertin, and emulsin. From this it may be concluded that chemical ferments belong to a special class of protein substances.

Diastase gives almost all the reactions of albuminoids but the one so characteristic of peptones—viz., the biuret reaction. One reaction, which no other protein body shows, diastase gives most distinctly—viz., the reaction with alcoholic guaiacum tincture. One drop of a solution of diastase causes an intense blue colouration, which appears within a few minutes, even if traces are present. In conclusion, the author thinks that though differing in composition, diastase shows considerable similarity to the albuminous bodies. Since the largest amount of diastase is produced during germination, and the latter process must, to a certain extent, be looked upon as one of oxidation, it does not seem improbable that diastase is an oxidation product of certain protein substances.—A. R.

Improvements in Apparatus and Mode of Holding or Containing Bicarbonate of Soda for Generating Carbonic Acid Gas, to be used in Aërating and Causing to Flow from the Barrel Draught Ale or other Beverages. W. A. How, New Malden, Surrey. Eng. Pat. 4194, March 25, 1886. 8d.

A CYLINDRICAL stoneware jar contains an inverted bell jar, to the top of which a tap is fixed for the admission of air and the escape of any gas generated. The bell-jar contains an arrangement for holding in its place sodium bicarbonate in a bag of textile material, or a separate holder with perforated sides.—S. H.

Improvements in the Manufacture of Yeast. W. S. Squire, London. Eng. Pat. 5457, April 20, 1886. 4d.

THE yeast is grown in a mixture of a solution of "peptonised maltose" (Eng. Pat. 11,935, 1885; this Journal, 1886, 542) and spent wash and wort, prepared by boiling maize, buckwheat or rice with water containing a little acid. The acid is neutralised with an alkali, the grain, together with the water in which it has been boiled, added, to either ground malt alone or ground malt mixed with ground raw grain, and mashed at 140° F. for an hour and a half. The clear spent wash from a previous distillation is added to this in such a proportion that the mixture shall have a sp. gr. of 1·040.
—G. H. M.

Improvements in the Manufacture of Aërated or Gaseous Waters or Beverages. J. C. Mewburn, London. From E. Bourcond, Madrid, Spain. Eng. Pat. 5834, April 29, 1886. 4d.

THIS invention consists in the employment of nitrogen gas in the manufacture of aërated beverages. The nitrogen is obtained from the air by the withdrawal of oxygen therefrom by means of phosphorus. The gas is first purified by passing through a weak solution of sodium hydrate, and then injected at a suitable pressure into the water or liquid to be aërated or rendered gaseous.—S. H.

XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, Etc.

(*A*) CHEMISTRY OF FOODS.

Improvements in the Treatment of Rennet. C. Hansen, Copenhagen, Denmark. Eng. Pat. 2909, March 1, 1886. 6d.

THE rennet ferment is precipitated in such a manner as to contain substances, such as pepsin or peptonised matters, which are themselves inert and protect the rennet subsequently from the effects of the atmosphere. After admixture with salt, sugar or other substance which is both inert and soluble in water, the precipitated material is pressed into a solid mass of such a size that each piece shall contain a fixed quantity of rennet, the necessity of weighing being thus dispensed with. The requisite number of pieces are dissolved in water prior to being added to the milk.—C. C. H.

Poisoning Sheep by Sorrel. Biermann. Bied. Centr. **15**, 858.

OUT of twenty sheep put to graze on an oat-stubble field, where there was a considerable growth of sorrel (*Rumex acetosa*), seven were taken ill, and of these two died.—D. A. L.

Simple Method of Preserving Hay or After-Math. W. Wagner. Bied. Centr. **15**, 860.

THE author recommends ensiling under pressure. He adds that the sweet silage is eaten readily by cattle, whereas sour silage increases the yield of milk.
—D. A. L.

Nutritious Value of some Edible Fungi. C. T. Moerner. Zeits. für Physiol. Chem. **10**, 503—516.

In these investigations only those parts of the fungus usually eaten were experimented upon. The fungi employed and the scope of the experiments will be seen from the following table of results:

Latin Name.	Common Name.	Nitrogen per cent. Dry Matter.						
		Soluble in		Albuminoid.			Extractive or Non-Albuminoid.	Total.
		Pancreatic Juice.	Gastric Juice.	Digestible.	Not Digestible.	Total.

In the digestive experiments, the substance was first treated with gastric juice, then the insoluble residue was treated with pancreatic juice, the finally insoluble portion being the indigestible matter. The average percentage of albuminoids present in the dry matter is 15·7, of which over half (8·7 per cent.) is digestible, and therefore on this basis, the nutritious value of these fungi is very near that of cabbage with 13·5 per cent. of albuminoids in the dry matter, and much below that of most other fresh articles of food, whether animal or vegetable. —D. A. L.

(*B*) SANITARY CHEMISTRY.

Microscopic Flora in Sulphur Springs. L. Olivier. Compt. Rend. **103**, 556—559.

Organisms have been observed in all cold or warm sulphurous spring waters examined by the author, even in those of a temperature of 55°; in fact, the organisms can withstand a temperature of nearly 70°. In cold waters, the organisms are Leptothrix, in filaments of colourless cells; whilst in warm water, they consist of uni-, bi- or, at the most, quadri-cellular bacilli. Some are elongated, some resemble bacteria; their membranes contain an iron salt. They form in a somewhat slimy, flocky, grey or colourless mass, which adheres to the stones, and contains microscopic crystals of sulphur and other inorganic matter. Both the warm and cold-water organisms contain granules of sulphur in their cells, and exert a reducing action on the sulphates present in the waters. The form of the warm-water organisms varies with the physical conditions, hence they appear longer at lower temperatures. In an experiment with the slimy matter from warm sulphur springs, long filaments were developed in 20 days at the ordinary temperature, consequently the elements of Leptothrix cells are present in the slimy matter.—D. A. L.

A New or Improved System of Treatment of Sewage. F. H. Daachell, Maidstone. Eng. Pat. 2439, Feb. 19, 1886. 6d.

The sewage is defecated, the resulting sludge filter-pressed, and, lastly, carbonised in retorts. If not sufficiently rich in carbonaceous matter, substances such as sawdust, peat, blood or offal, etc., are previously mixed therewith. The carbon, after carbonisation, the patentee terms "charcoaline," and proposes to use it either for the purification of sewage or the decolouration and purification of water, sugar, vinegar, etc.—C. C. H.

Improvements in Treating Sewage and Making Cement. J. B. Hannay, Glasgow. Eng. Pat. 3217, March 8, 1886. 4d.

Lime or carbonate of lime is added to the sewage in conjunction with clay; the resulting sludge is dried by evaporation, heated to redness, cooled, and ground. —C. C. H.

Improvements relating to the Purification of Water. C. W. Burton, Nogent; F. T. Moison, Mony, France Eng. Pat. 3730, March 16, 1886. 6d.

Calcined dolomite is employed, either in conjunction with or without carbonate or oxalate of baryta, for the removal of carbonate or sulphates held in solution in a water.—C. C. H.

XVIII.—ELECTRO-CHEMISTRY.

Improvements in the Method of Depolarising Electric Batteries. A. C. Henderson, London. From E. Bazin, Paris, France. Eng. Pat. 3577, March 13, 1886. 11d.

In order to prevent polarisation, the inventor makes use of carbon discs mounted upon a rod, suspended in bearings over the cells at such a height, that part only of the discs dips into the battery solution. The rod is made to rotate by means of an electro-motor, driven by the current from two or three of the elements, and by its rotation it brings fresh surfaces of carbon into contact with the liquid.—B. T.

Improvements in Electro-plating Apparatus. A. F. Harris, Walsall. Eng. Pat. 3674, March 16, 1886. 4d.

To prevent the suspending wires or hooks of electroplating baths becoming coated with a metallic deposit, the inventor covers these wires with an insulating varnish of enamel, indiarubber or other suitable insulator. —B. T.

Improved Means for Producing Ozone and Hydrogen suitable for Bleaching Purposes. J. H. Johnson, London. From E. Hermite, Paris, France. Eng. Pat. 3956, March 20, 1886. 8d.

The patentee has found that when sulphate of soda, sulphate of potash, caustic soda, potash or baryta, either pure or in a state of mixture, are subjected to electrolysis, using an unattackable or in-corrodible positive electrode such as platinum or carbon with a negative electrode of mercury or an amalgamated metal such as copper, tin, zinc or iron, an amalgam of the metal set free is obtained at the negative pole, while ozone or ozonised oxygen is obtained at the positive pole. If the passage of the current be interrupted, or the apparatus short-circuited, the water is decomposed by the amalgam with abundant evolution of nascent hydrogen. The inventor applies these reactions to bleaching purposes by utilising this ozone and nascent hydrogen, and makes use of an apparatus constructed and arranged as follows:—A layer of mercury at the bottom of a tank or cistern is connected with the negative pole of an electric generator: at a short distance from the layer of mercury is situated the positive electrode, constituted by one or more plates of platinum or carbon perforated with holes to facilitate the escape of gases. The trough is afterwards filled up with a solution of any of the substances before referred to. The materials to be bleached are immersed in this solution, where they are acted on by the ozone, the ozonised oxygen or the nascent hydrogen produced, the alkaline or earthy alkaline metals produced being absorbed by the mercury in the process of electrolysis. Other modifications are described.—J. H.

Improved Means for Producing Chlorine Compounds suitable for Bleaching Purposes. J. H. Johnson, London. From E. Hermite, Paris. Eng. Pat. 3957, March 20, 1886. 8d.

The inventor employs an apparatus similar to the one described in Eng. Pat. 3956 (preceding abstract) for the electrolysis of chlorides of the alkali or alkaline earth metals. An amalgam of the alkali with the mercury is formed at the negative pole, while chlorine compounds are obtained at the opposite pole. The goods are immersed as in the previous patent, and are bleached by the oxygen compounds of chlorine evolved.—J. H.

Improvements in Galvanic Batteries. A. Dun and F. Hasslacher, Frankfort-on-the-Main, Germany. Eng. Pat. 5731, April 27, 1886. 6d.

In this improved two-cell battery, a carbon negative element is immersed in aqua-regia contained in one cell, and a positive element of zinc, or other soluble metal, is used in the other cell, which contains soda-lye. The hydrochloric acid of the aqua-regia may be replaced by chromic acid or a chromate, and ferric chloride may be used in addition.—B. T.

Improvements in Incandescent Electric Lamps. B. J. B. Mills, London. From W. Holzer, Harrison, New Jersey, U.S.A. Eng. Pat. 5979, May 3, 1886. 8d.

To overcome the difficulty caused by the breakage of a filament when incandescent lamps are placed in series, the leading-in wires pass in close proximity through a double-barrelled glass tube, or through two glass tubes bound together. If the filament breaks, an arc forms which burns down the leading-in wires until a point is reached at which they are close enough for the melted ends to coalesce, thus metallically completing the circuit. —E. T.

Improvements in Electric Secondary or Storage Batteries. W. Taylor, London. Eng. Pat. 6287, May 10, 1886. 8d.

To produce a very light electrode, a leaden frame is used with several vertical partitions; the spaces between these are bridged across by numerous horizontal leaden bands, corrugated so as to hold firmly the active material, which is placed between them. A small space is left near the top of the frame to allow expansion by sulphating to go on without injury. The active material may, when formed, be perforated, to allow of free circulation of the liquid, and reduce the weight of the electrode. A short piece of copper is soldered to the electrode for a terminal; suitable copper bars are let into opposite sides of the top of the box, and to these the terminals of the electrodes are soldered.—E. T.

An Improved Form of Galvanic Cell for Bell Ringing and other Purposes. G. H. Bays, jun., Wakefield, Yorks. Eng. Pat. 6604, May 17, 1886. 4d.

This element consists of a porous cell contained in a non-porous earthenware jar, the space between the two vessels being packed with fine gas-retort carbon, with or without the addition of manganese dioxide. A rod of carbon is packed in with the broken carbon to serve as the negative electrode. The porous cell contains a rod of zinc immersed in a solution of a suitable salt, such as chloride of sodium; dilute sulphuric or hydrochloric acid, etc., may be employed.—B. T.

An Improved Regulator combined with a Portable Battery for Controlling the Light of Incandescent Electric Lamps used for Surgical and other Purposes. J. B. Medland, London. Eng. Pat. 12,779, Oct. 7, 1886. 8d.

Round a piece of insulating material is wound a spiral wire of high resistance. Surrounding, but insulated from it, is a metal cylinder, having a slot along its under side. A ring, sliding on this, has a projection, which, passing through the slot, makes contact with the wire inside. The current, entering at one end of the wire, reaches the ring and passes thence to the outside cylinder, which is joined to the rest of the circuit. —E. T.

XIX.—PAPER, PASTEBOARD, Etc.

On the Strength of Paper as influenced by Sizing, Satining and the Amount of Wood-Fibre contained in it. A. Martens. Dingl. Polyt. J. **263**, 120—124.

According to the author, paper which has been sized with *animal* gluten (gelatin) is very considerably improved in every respect as compared with paper only treated with vegetable glutin. The strength, however, does not increase with the number of times the paper is sized, not more than two treatments being, in fact, advantageous. With an increase of the amount of woody fibre contained in paper, the strength is notably diminished. Paper sized with resin shows lower values in the "tearing length," tension and modulus of work, than paper sized with animal gluten or unsized paper.

Soil, which is frequently added to weight the paper, has a most injurious effect on the strength. Even such papers, however, are considerably improved by twice sizing with animal gluten. It is furthermore stated that satining increases the "tearing length," no matter in which direction the strip experimented upon is cut from the sheet of paper, or in which direction it is satined. This increase, however, varies according to whether the strip of paper has been cut parallel or at right angles to the course of the machine. In the latter case it is about 13 per cent., in the former only 5 per cent. The medium tension is hardly altered. The thickness of the paper decreases by satining, the weight does not change appreciably. It is important to notice that the paper experimented upon was made of linen and cotton fibre, and the results cannot, therefore, apply equally to paper of a different manufacture.

For all practical purposes the author thinks that different kinds of paper, whose strength ("tearing length" and tension) does not differ by more than ±5 p.c., may be regarded as of equal quality, other properties and peculiarities of the papers being equal.—A. R.

Improvements in Manufacturing or Preparing Asbestos for use as a Non-Conductor of Heat and otherwise. W. Finlayson, Glasgow. From R. H. Martin, New York, U.S.A. Eng. Pat. 10,891, Aug. 26, 1886.

The sheets or coverings may be of various forms, and are composed of superimposed "slivers," or fleeces of asbestos fibre. The asbestos is not pulped, as in the manufacture of paper or millboard, but is cast through a carding machine—the fleece so formed, being deposited in even layers upon an apron or table, or coiled upon a rotating cylinder until a sufficient thickness is obtained. Water, or a sizing substance (preferably a solution of silicate of sodium), is uniformly applied to the asbestos, at some convenient stage between its raw condition and its deposition in layers. No felting operation is employed, but pressure, regulated according to the required density, is applied by means of a roller or otherwise. For some purposes hair, wool, mineral wool, finely-divided clay, infusorial earth, etc., may be mixed with the asbestos fibre. The sheet or covering, when dried, forms a flexible elastic material resembling felt, is non-conducting, and may easily be made waterproof. It may be bent and adapted to slightly curved or irregular surfaces.—E. G. C.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

The Pepsins of Commerce. C. Schlickum, Brit. and Col. Druggist, March 12, 1887 (Zeit. Oestr. Ap. and Ver.).

Numerous varieties of both "concentrated" pepsins, prepared by precipitation according to Scheller's process, for "scale" pepsins are manufactured, the digestive strengths of which are much higher than that of the officinal saccharated pepsin. The author has examined the strengths of several of these pepsins of higher digestive power, by digesting them for six hours at a constant temperature with a known weight of albumen, and then determining the amount of undissolved albumen. The results show that the "concentrated" pepsins have on the whole a greater digestive power than the "scale" pepsins, while the claims made by the manufacturers of both varieties are greatly at variance with their true digestive powers.—C. A. K.

On Magnolia-Bark. J. U. and C. G. Lloyd. Pharm. Rundsch. **4**, 266.

Commercial *cortex magnoliae* comes from the mountains of North Carolina, and is collected from *magnolia glauca, umbrella* and *macrophylla*. The bark was extracted with alcohol, the latter evaporated, resinous matters being left behind, which apparently were a mixture of three different resins. The residue was taken up with water, which, after a few days, gave colourless crystals, which were recrystallised from alcohol. They were then dissolved and boiled with dilute sulphuric acid, the solution neutralised with barium carbonate, and filtered. The filtrate reduced Fehling's solution, and it is, therefore, very likely that the crystals represented the magnolia glucoside. Experiments for obtaining an alkaloid from the resinous residue were unsuccessful, although the usual reagents for alkaloids pointed to the presence of an alkaloid.—S. H.

Asiminin, a New Alkaloid. J. U. and C. G. Lloyd. Pharm. Rundsch. **4**, 268.

The alkaloid was obtained from the seeds of the fruit of *Asimina triloba*. The powdered seeds were extracted with alcohol, the latter mostly driven off, the residue mixed with water to separate the essential oil, and after acidifying with acetic acid, put aside for twenty-four hours. The mass was filtered, rendered slightly alkaline with ammonia, and the precipitate repeatedly shaken with ether. On evaporating the latter, the alkaloid remaining behind was dissolved in alcohol, and converted into the hydrochloride, which was recrystallised several times. The free base was then precipitated with ammonia. It is amorphous, colourless, tasteless and without smell, insoluble in water, and easily soluble in alcohol and ether. Nitric acid colours asiminin and its salts at first carmine-red, then deep violet. Chlorine water does not act upon the free alkaloid, but the hydrochloride is precipitated. The hydrochloride crystallises in colourless plates and cubes. The composition of the alkaloid has not yet been definitely ascertained.

—S. H.

Improved Process for Manufacturing Tannic Acid in Crystals or Grains. Dr. H. Byk, Berlin, Germany. Eng. Pat. 15,436, Nov. 26, 1886. 4d.

The patentee prepares a granulated tannic acid by dissolving it in a suitable solvent, and adding 5 per cent. alcohol containing 0·05 per cent. glycerin. This solution is evaporated down and spread out to dry on sheets of zinc or other metal from which it can then be detached in semi-transparent grains. The glycerin may be replaced by gum or carbohydrates.—R. L. W.

Cholestrin in Carrots. A. Arnaud. Compt. Rend. **102**, 1319—1322.

In investigations with carrots, the author obtained an impure cholestrin, which he found to be identical with Husemann's hydrocarrotin. The impure substance was purified by repeated treatment with alcohol, until the melting point was constant. The cholestrin obtained in this manner has the composition $C_{26}H_{44}O$, it is insoluble in water, slightly soluble in cold but readily in boiling alcohol, from which solution it crystallises on cooling in leaflets with 1mol. H_2O. It is also very soluble in ether, carbon bisulphide, chloroform, light petroleum and oils, from which solutions it is deposited in anhydrous needles. It is not attacked by alkalis nor by acids. It is lævo-rotatory, the rotatory power of the chloroform solution being $[\alpha]_D = -35°$. It melts at 136·5, losing the 1mol. H_2O. It will be observed that the cholestrin from carrots is identical with that obtained by Hesse from Calabar beans and from peas, and differs only very slightly from animal cholestrin.—D. A. L.

Occurrence of Cholestrin in Vegetable Fats. E. Heckel and F. Schlagdenhauffen. Compt. Rend. **102**, 317—319.

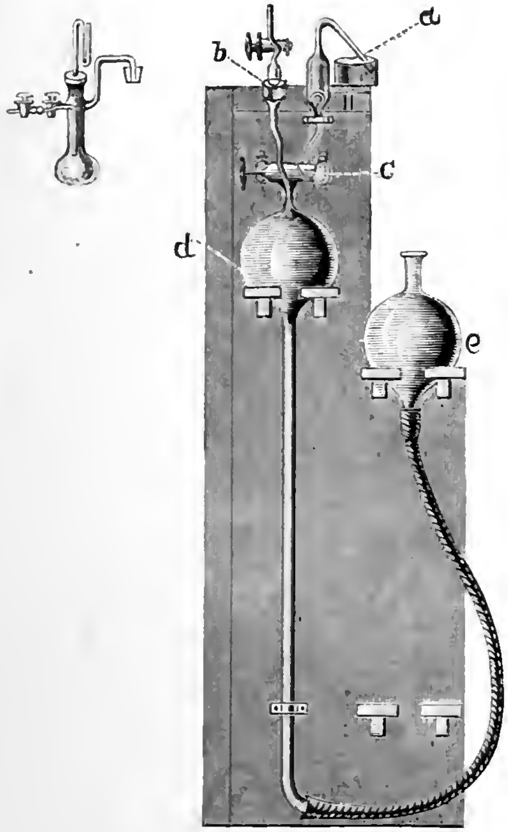
The authors have isolated cholestrin from the seed-oils from *Gynocardia odorata, Giulandina, Bonducella* (chick stones), *Cæsalpinia Bonducella, Abrus precatorius* (wild liquorice), and from the fat and wax extracted from the leaves of *Erythoxylum hypericifolium* (Hypericum-leaved red-wood). Two modes of investigation were followed. In one the oil or fat was boiled with alcohol and the alcoholic extracts allowed to crystallise; when, after about a month, they deposited leaf-like crystals melting at 134—138°. In the other a portion of oil or fat was saponified, and the soap extracted with ether; on evaporating the ether extract, rhombohedral tables or fine needles melting at 135—138° were deposited. In both cases the crystals had the physical and chemical properties of cholestrin, giving the colouration with sulphuric acid, chloroform and ferrous chloride, etc.

—D. A. L.

XXII.—GENERAL ANALYTICAL CHEMISTRY.

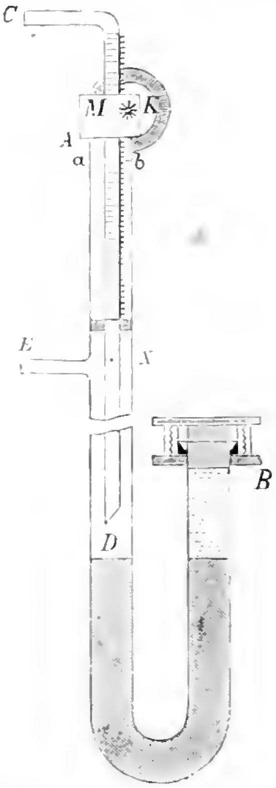
Mercury Air-Pump. Greiner and Friedrichs. Chem. Zeit. **10**, 277.

The apparatus is a modification of Geissler's pump. The principal novelty is a new form of three-way tap *c*, consisting of two passages, which are bored obliquely to the axis of the plug. All the taps are also fitted with a mercury lute. The working of the pump is very simple. The tap *c* is connected with *a*, and the reservoir *e* is raised until mercury enters the tube *a*. The connection of *c* and *a* is then interrupted, *e* is lowered and *d* connected with *b*. Air thus enters *d*, which is then driven out through *a*; a vacuum is again formed by lowering *e*, and so forth.—S. H.



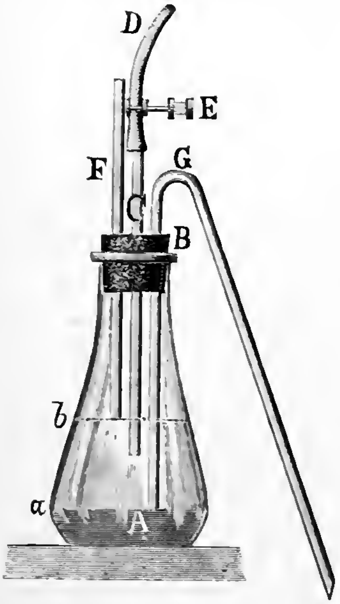
Thermo Regulator. G. W. A. Kahlbaum. Ber. **19**, 2860—2862.

THE author has constructed a thermo regulator similar to Andreae's. The U tube A B, open at both ends, has a short side tube E, the gas exit tube, blown on the longer limb. The mouth of this limb is closed with a brass cap M, through which passes a narrow graduated tube bent at right angles and carrying a toothed rod. This tube can be raised or lowered by means of the wheel K. It also carries a small piston, with which the large tube is made air-tight. On the under side of this the tube C D has a small hole X, and the lower end is cut off obliquely. The large U tube A B is filled with mercury to within 4cm. of the end B, and 2cm. of a liquid. This end is closed by means of a cork, which is kept in its place by a brass screw cap. If, before putting in the cork, the tube A B be sloped until the liquid rises to the edge, the cork may be put in without any air being between it and the liquid. When now the lower part of the regulator is heated above the boiling-point of the liquid, the mercury *niveau* is regulated by the elastic force of the vapour of the liquid, and not by the mere expansion of the liquid itself. The mercury rises and partly or wholly covers the mouth of the narrow tube C D. Should the mouth become entirely closed, a small jet of gas still remains, the small hole X supplying this. It is, therefore, only necessary to put suitable liquids in the end B, and the regulator may be used for all temperatures between —40° and +360° C. The author found it to keep temperatures constant to 0·1° C. The graduation of the tube C D enables the operator to fix the tube exactly in the same position again after being put away, thus being sure of starting again with the same temperature.—J. W. L.



A Simple Apparatus for Washing Precipitates Automatically. A. Wahl. Chem. Zeit. **11**, 4.

THE apparatus consists of a flask A, an indiarubber stopper B with 3 holes, a feed-pipe C with the screw-slip E on the indiarubber tube D, an air-tube F and a siphon G. The long leg of the siphon is placed above



the filter to be washed. The washing liquor runs into the flask from above through the pipe C, the flow being regulated by the clip E in such a manner that the rise of level from *a* to *b* takes a little more time than is required for the washing on the filter to run through it. As soon as the level *b* is reached, the air can no longer escape through F; the siphon is thus made to run until the level has sunk to *b*, when it stops of itself. The liquor in A then rises again, and the play of the siphon is repeated. If it be desired to wash the filter with hot liquor, the flask A may be heated in any convenient manner.—S. H.

Apparatus for Chemical Laboratories. Dr. T. Walter. J. Prakt. Chem. **34**, 1886, 427–432.

THE condenser recommended by the author is constructed on a principle the reverse of Liebig's—*i.e.*, while in the latter the vapour is condensed from the outside, the author passes the condensing water through the inner tube, the cooling from outside being effected merely by the air. With the intention of making the condenser as short as possible without influencing its efficiency, the condensing surface is increased by blowing five, eight, or more bulbs on one outside tube. Fig. 1 represents such a condenser suspended in a flask; when experimenting on a small scale the dimensions are: diameter of round-bottomed flask 90mm., diameter of neck 20mm., and length 180mm. The condenser consists of a glass tube 5mm. wide, on which the small bulbs, 16mm. in diameter, are blown; to the tube at *c* a somewhat wider tube is attached, and to this the side piece *d* is fused. To construct the thin tube (1·5—2mm. wide), which reaches to the inside of the lowest bulb, a piece of tubing is chosen which fits easily in the upper tube *c*. This is then drawn out and the wider part *f*, which has not been drawn out, is passed down through *c* as far as possible, and the two tubes joined by caoutchouc tubing or fused together. To one of the upper and lower bulbs three small glass buttons are fused at *v*, to prevent the cold condensing surface from touching the hot neck of the flask. The water enters either at *d* or *f*. In the apparatus ether may be boiled vigorously (the temperature of the water used for condensing being 13°) without the slightest loss. The small bulb condenser is either suspended by the side piece *d*, or slung, by means of a wire round *c*, to the neck of the flask. Should noxious gases be evolved during the reaction, these may be drawn off by putting a tube bent at right angles in the open neck of the flask and attaching the other end of the tube to an ordinary air-pump. The author also describes some improved apparatus for distilling substances that attack caoutchouc or cork (Figs. 2 and 3). The latter arrangement is used when the vapours are not readily condensed. The condensers here shown are straight, but it is better to employ bulb-condensers. The retort neck is ground and fitted into the receiver at *c*. With the apparatus

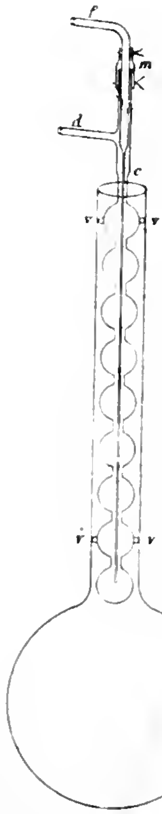


Fig.1.

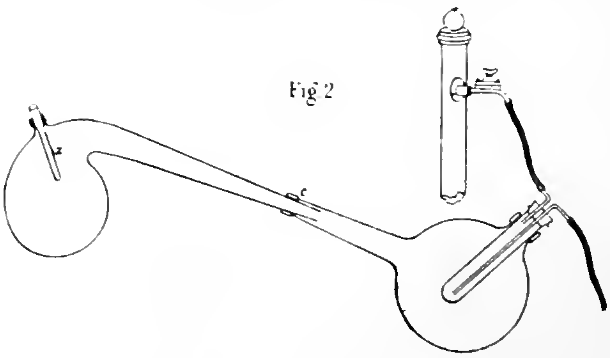

Fig.2

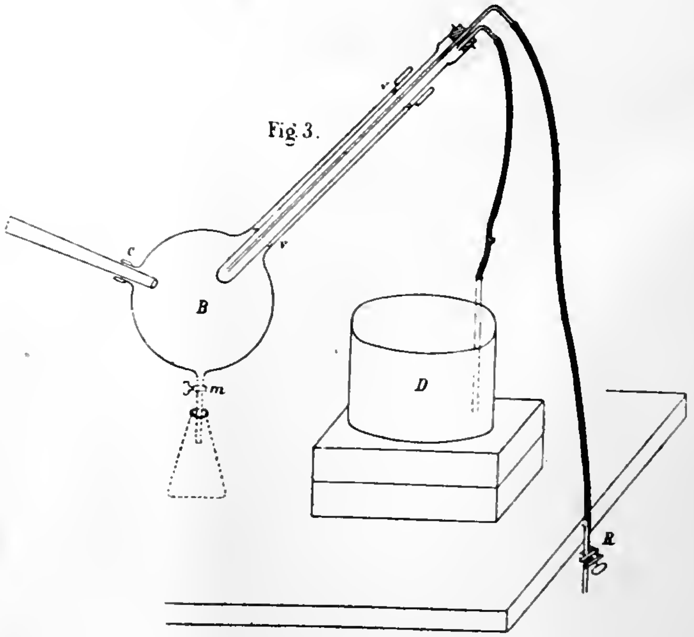

Fig.3.

Fig. 3, the distillate can also be drawn off fractionally, if to the receiver a tube *m* be jointed, furnished with a glass stop-cock. If the condensing water is to be very cold, the vessel D is filled with ice and water; the condensing tube, as will be seen in the figure, forms one limb of a siphon, and is previously filled with water. The flow of the water is regulated by the screw R. A method is also given for working with condensing water of −15°. In Fig. 2, *z* is a glass tube closed below and ground into the tubulus of the retort; it serves for holding the thermometer and a little mercury. To combine the operations of heating with reflux condenser and then distillation, flasks of the shape shown in Figs. 4 and 5 are recommended. Bulb condensers (omitted in the sketch) are suspended in the upper part of the tube, or Liebig condensers are attached. For heating with reflux action the side tube is turned upwards and closed with a stopper, or merely by a small glass rod, fitting tolerably well into the tube. For distilling, the flask is turned 180° on its axis; the side tube now has the position shown by the dotted lines in Fig. 4, the fluid which previously returned over the brim of the inner tube into the flask, now flows out. If a narrowing of the tube is objectionable, the construction of a flask (Fig. 5) is useful, particularly when solid bodies, such as PCl_5, are to be brought into the flask. This is effected by means of a funnel having a long and wide tube reaching into the flask. The last-named arrangements are impracticable for substances with low boiling points. They are peculiarly adapted in cases where the distillate solidifies readily—*e.g.*, acetanilide. In many cases air is amply sufficient for condensing purposes when the bulb-condenser is employed; when fractionating, air is even preferable, the current of air being drawn through the apparatus by an ordinary air-pump.—A. R.

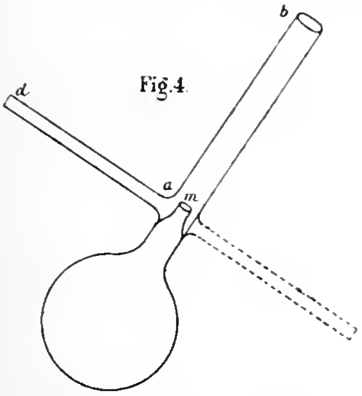

Fig.4.

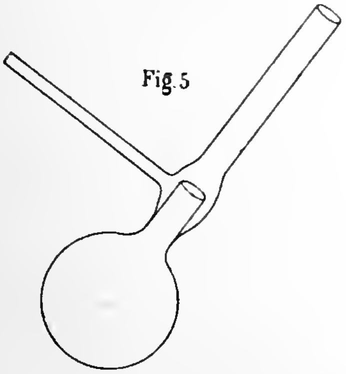

Fig.5

Apparatus for Extracting Aqueous Solutions. E. Grauer. Dingl. Polyt. J. **262**, 475—477.

This apparatus is intended for the extraction of substances contained in a solution, in a finely-divided or soluble condition, by means of a solvent of higher or lower specific gravity. Fig. 1 represents the apparatus used for extracting aqueous solutions with a solvent of higher sp. gr., such as, for instance, carbon bisulphide. The tank A contains the solvent, and B the aqueous solution. The solvent is run into the apparatus C at *d*, to the level of *a*; the valve *b* is then opened, and the aqueous solution allowed to proceed through the apparatus. The solvent being heavier than the aqueous solution, remains in the lower part of the spiral pipe of C, so that the solution in ascending the apparatus is brought into intimate contact with the solvent, resulting in a complete extraction of the substance to be separated. The saturated solvent is then removed to D, through the pipe *a*, and may be recovered by distillation, whilst the extracted solution passes through *c*, and is collected in E. The apparatus illustrated in Fig. 2 is used for the extraction of aqueous solutions, with a solvent lighter than water. In this case, the solution in A is introduced into C, at *d*, whilst the solvent enters the apparatus at *b*. The saturated solvent is run off at *c*, and the treated solution at *a*.—D. B.

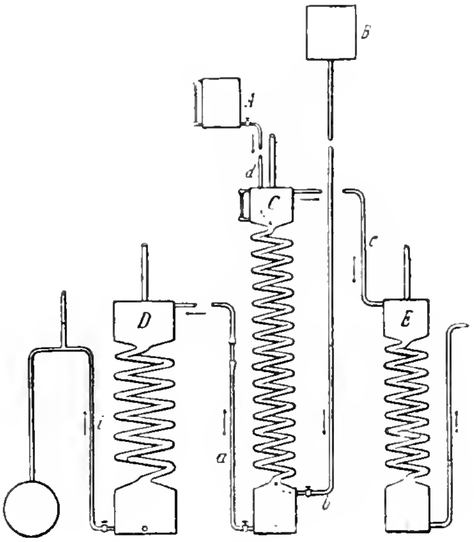

Fig. 1.

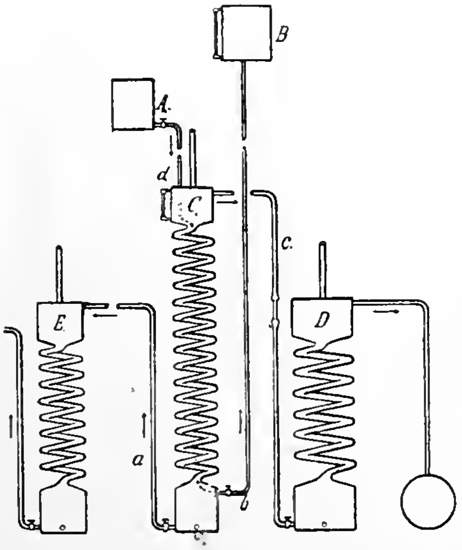

Fig. 2.

Sensitive Reagents for Detecting Minute Quantities of Active Oxygen. C. Wurster. Ber. **19**, 3195–3205.

IN the course of some researches on the influence of the natural and artificial climate of habitation and clothing on the circulation of the blood, it was found needful to study the condition of the blood in proximity to the skin of the body, various observations made by the author having shown that oxidation takes place in the skin, and that certain secretions of the body and skin possess powerful oxidising properties. Attempts to detect ozone or hydrogen peroxide in animal tissues by the ordinary tests having been unsuccessful, the author instituted a series of experiments, the object being to discover if possible some reagents which would admit of the ready detection of active oxygen. It was found that the methyl derivatives of phenylenediamine produced delicate colour reactions with active oxygen, tetramethylparaphenylenediamine being the most sensitive reagent, producing an intense blue colouration with oxidising agents. This base does not undergo any change on exposure to the atmosphere, and resists energetically the action of acids, alkalis, and reducing agents. The author has experienced no difficulty in detecting minute traces of active oxygen both in a free and combined form by employing this reagent. With paper rendered sensitive by impregnation with a solution of tetramethylparaphenylenediamine he has succeeded in proving the presence of ozone in air, in the proximity of a flame and in the sap of plants. He has also detected active oxygen on the surface of the skin of the human body.—D. B.

A New Method of Determining the Flashing Point of Petroleum. Th. Rosenbladt. Chem. Zeit. **10**. 1587.

THE Abel-Pensky apparatus, which is the only contrivance universally adopted for the determination of the flashing point, requires at least from 75 to 100cc. of petroleum for a test. If only a smaller quantity is at disposal, the test cannot be performed, and in those cases the author recommends the following method:—A flask is filled with water to two-thirds of its capacity, and closed with an indiarubber stopper, fitted with two holes, through one of which goes a Welter's safety tube, luted with a little mercury, and through the other a bent glass tube. A Woulf's bottle of 100 to 150cc. capacity contains 12·5cc. (10grms.) of the petroleum to be tested, and the same amount of distilled water. One opening of this bottle is closed with a stopper, into which is inserted a tube, which reaches nearly to the bottom, where it is drawn out to a fine point (1½mm.). This tube is connected with the flask. The Woulf's bottle is covered with cloth, to protect it from cooling. The second opening is connected with the condensing tube of a Liebig's condenser, the other end of which dips in a dry measuring tube of 5 to 6cc. capacity, divided into 20ths of a cc. The contents of the flask are then boiled, until 5 to 5·1cc. have collected in the measuring tube, when the latter is exchanged for another, and the distillation continued until a further distillate of 5cc. has condensed. The liquid in the tubes is allowed to cool to 15° C.; both the total volume and the oily layer on the top are read off, and their proportion noted down. The following table shows some of the results obtained in this manner:—

Petroleum having the Flashing Point at			Proportion of Aqueous to Oily Liquid (Factor).
20° C.	From the works of Messrs. Tagieff.	Baku.	1 : 0·697
21° ,,			1 : 0·673
22° ,,			1 : 0·650
23° ,,			1 : 0·626
21° ,,	From Messrs. Mirsoeff.		1 : 0·598
25° ,,			1 : 0·572
26° ,,	From Messrs. Kokoreff.		1 : 0·549
27° ,,			1 : 0·526
30° ,,	From Messrs. Nobel Bros.		1 : 0·461
45° ,,	American Petroleum.		1 : 0·328

It will be noticed that the factor varies nearly in proportion with different flashing points, and although this method does not claim absolute accuracy, the result does not differ from that obtained with the Abel apparatus by more than ± 1. In order to avoid mistakes due to the variation of barometric pressure, it is important to distil some normal standard petroleum at the same time, under the same conditions, and to make the necessary corrections accordingly.—S. H.

Detection of Lead in Zinc Preparations. Chem. Zeit. **11**, 18.

THE testing of zinc oxide for lead, according to the direction of the German Pharmacopœia—viz., adding sulphuretted hydrogen to the solution of the zinc compound in acetic acid—is not sufficiently delicate for the detection of minute quantities of lead. Mylius now publishes a method by which the smallest traces of lead can be detected. The zinc oxide is dissolved in warm dilute sulphuric acid. An absolutely clear solution shows *a priori* the absence of lead, but in most cases the solution will be turbid. It is filtered, and the precipitate well washed. The filter is then digested in a warm 20 per cent. solution of ammonium acetate for several hours, whereby any lead sulphate present is converted into lead acetate and dissolved. The solution is then filtered, and traces of lead can be detected in the filtrate by sulphuretted hydrogen or potassium bichromate. This method is far more sensitive than that of the Pharmacopœia.—S. H.

Estimation of Phosphoric Acid in Thomas Slag. C. Brunnemann. Chem. Zeit. **11**, 19.

TEN grammes of slag are digested in a beaker with about 40cc. of water, 90cc. of hydrochloric acid, 50cc. of nitric acid and 10cc. of sulphuric acid. The beaker is then covered and heated over a flame for about three-quarters of an hour. The hot solution is then poured into a litre flask, which contains about 400cc. of hot water, and the beaker rinsed with hot water. The flask is then shaken, in order to dissolve all the calcium sulphate, filled up to the mark, and allowed to cool. The insoluble matter consists of silica and carbon. 50cc. of the clear solution are then evaporated on the water-bath, the hydrochloric and nitric acid is driven off, and the free sulphuric acid neutralised with dilute ammonia (1 : 5). The mass is then evaporated to dryness and heated to 110° C. for ten minutes, to render the silicic acid insoluble. The residue is stirred with 10cc. of strong nitric acid, and 50cc. of hot water then added to dissolve the calcium sulphate. The solution is filtered from the silica and the filter washed with hot water. The phosphoric acid in the filtrate is then precipitated by ammonium molybdate. This method also converts the iron phosphide into phosphoric acid, but this is fair to the consumer, as Jensch has shown that the phosphide soon changes in the soil to phosphoric acid.—S. H.

Treatment of Tin Ore. W. Hampe. Chem. Zeit. **11**, 19.

TIN ORE is usually rendered soluble for analytical purposes by fusion with alkali-hydrates or sodium carbonate and sulphur. The following method gives excellent results and is more convenient:—The finely-powdered mineral is placed in a porcelain boat and strongly heated from one to two hours in a combustion tube, dry hydrogen being passed over it all the while. The water given off during reduction is absorbed and weighed in the usual manner. After cooling, the contents of the tray are dissolved in warm dilute hydrochloric acid, and the solution filtered from the residue. The tin is precipitated with sulphuretted hydrogen, and both precipitate and filtrate are treated in the usual manner. If the mineral is finely powdered, all the tin is rendered soluble. The process has the further advantage of removing the insoluble silicates and aluminates at once, which may then be examined separately.—S. H.

Wiborgh's New Colorimetric Test for Sulphur. Jüptner. Oesterr. Zeits. f. Berg. u. Hüttenw. **34**, 805.

THE author examined Wiborgh's method (*Chem. Zeit. Repert.* **10**, 92) as regards accuracy, and highly recommends it for practical work. He adds that it can be applied in all those cases where sulphuretted hydrogen is expelled by boiling or the addition of an acid—*e.g.*, in the determination of sulphur in mineral waters, black ash, slag, etc. By converting combined sulphur into an alkaline sulphide, the method can be made still more generally applicable. It may also be mentioned that Wiborgh's colour-scale must be kept in the dark.

—S. H.

Analysis of a Copper Slag of a Bright Red Colour N. A. Berry. Amer. Chem. Journ. **8**, 429—430.

No doubt this slag is familiar to all copper smelters engaged in the process of refining copper, in which process it is occasionally produced. It is very tenacious and hard, has a conchoidal fracture with splintery edges, and has, scattered throughout its mass, small spherical cavities and very minute metallic beads; it is opaque, and its colour varies from bright to darker scarlet. Sp. gr. = 2·987; hardness = nearly 6. The portion insoluble in acids, consisting of silica and a pale yellow powder, was fused with soda and examined separately.

			Molec. ratio.
Soluble in acids :			
Copper	2·50		—
Cuprous oxide	27·05	..	18·95
Ferrous oxide	0·25	..	0·34
Alumina	0·13	..	0·12
Insoluble in acids :			
Cuprous oxide	8·64	..	6·05
Ferrous oxide	11·69	..	16·24
Silica	49·24	..	82·07
	99·80		

From the oxygen ratio for bases and silica 1 : 4, it appears that cuprous oxide can combine with a surplus of silica, as do the alkalis in petalite or orthoclase. It is also of interest to note the pale yellow colour of the insoluble silicate, which contains so large a percentage of iron and copper, probably presenting the effect of mixture of the complementary colours, green and red, which would belong respectively to the simple ferrous and cuprous silicates.—J. T.

Vanadium and Chromium Extraction from Iron Ores. E. Claassen. Amer. Chem. Journ. **8**, 437—443.

Soft ores, such as limonite, may perhaps be sufficiently finely powdered by crushing; but ores of considerable hardness, like magnetite, are treated with water and sulphuric acid to obtain an impalpable powder for fusion. A magnetite so prepared was treated by two methods.

(1.) *Treatment with Soda and Sulphur.*—The powder, mixed with six times its weight of equal parts of soda and sulphur, was exposed to a gradually increasing temperature in a well-covered porcelain crucible until most of the free sulphur was volatilised. The fused mass was lixiviated with hot water, filtered, and the filtrate acidulated with nitric acid. After standing some time the precipitate was filtered off, washed, dried and treated with carbon bisulphide to remove the free sulphur, leaving the vanadium sulphide as a chocolate-brown powder. This was incinerated with the filter, and the residue from the evaporated filtrates obtained above, in which there is always a small amount of vanadium present, added to it, with a small quantity of soda, and the whole ignited. The fused mass, green from the presence of manganate, was extracted with hot water, the filtered solution mixed with much ammonium nitrate and boiled. This addition of nitrate and boiling should be repeated until no further smell of ammonia is perceived. Not a trace of vanadic acid is reduced in this way. If nitric acid be used for neutralising instead of the nitrate, the liquid should never become acid for an instant, and should still be slightly alkaline at the end. The solution thus treated with ammonium nitrate, was filtered, precipitated with neutral lead acetate (or nitrate) the precipitate washed, digested for some time on the filter in a flask with a sufficient quantity of hydrochloric acid and alcohol. The precipitate thus formed was filtered off and washed with alcohol, the alcoholic liquids evaporated, the remnant mixed with water, treated with hydrogen sulphide, filtered, evaporated and ignited. The impure pentoxide thus obtained gave, after moistening repeatedly with ammonium nitrate solution, ignition and then extraction with ammonia or ammonium carbonate, a liquid which, when filtered, evaporated and ignited, left the exact amount of the vanadium pentoxide present excepting the merest traces, the vanadium being practically completely extracted by but one process. All the chromium in the ore remains undissolved in the residue after fusion with soda and sulphur. This residue was fused with six times its weight of equal parts of soda and nitre, and lixiviated and treated as below. This method is very good, particularly if the estimation of vanadium only is the object aimed at; if, however, the estimation of chromium be also required, it may be better to use the following mode of extraction, which gives nearly as good results, as regards the separation of vanadium.

(2.) *Treatment with Soda and Nitre.*—The ore, finely powdered by treatment with sulphuric acid, as described, was ignited with six times its weight of equal parts of soda and nitre, and extracted with hot water and filtered. Scarcely a trace of chromium, and but little more than a trace of vanadium, remain in the residue with care, and this trace may be recovered by an application of the process given under 1. The filtrate is evaporated to dryness and the residue fused, dissolved in hot water, filtered, boiled for some time, after addition of ammonium chloride, filtered again and evaporated so far as to avoid the separation of crystals after cooling and stirring for a while. Into this solution a lump of ammonium chloride was placed, large enough not to be dissolved completely; the separated ammonium metavanadate washed with saturated ammonium chloride solution and ignited. To purify the vanadium pentoxide, it was moistened with ammonium nitrate, ignited, dissolved in ammonia, evaporated until ammonia could scarcely be detected by the odour, then filtered, evaporated to dryness and ignited. Very exact analyses demand the collection of the small amount of metavanadate always remaining in the filtrate, and this is evaporated to dryness and ignited. The residue is digested with concentrated ammonia, filtered, and precipitated with alcohol. The precipitate, dissolved in a little water and precipitated with ammonium chloride, gives the residual ammonium metavanadate. From experiments made it appears necessary to employ a sufficient amount of soda and nitre in the fusion, at least three times the amount of ore of each, in order to obtain a good result. In course of this investigation a precipitate of lead chromate and lead vanadate was suspended in water, acidulated with nitric acid and treated with hydrogen sulphide, which decomposed it perfectly. A precipitate of the above lead compounds and of lead sulphate—the latter in considerable excess—did not give satisfactory results. In such a case, treatment with hydrochloric acid and alcohol will answer the purpose quickly and satisfactorily.—J. T.

Solubility of Manganese Sulphide in Melting Potassium Sulphide. E. Claassen. Amer. Chem. Jour. **8**, 436—437.

When experimenting with vanadiferous *magnetite*, the crushed ore was treated with an equal weight of water and double the amount of sulphuric acid of sp. gr. 1·840. The nearly dry mixture was subjected to a slowly-increasing temperature until the water, sulphuric anhydride and sulphur dioxide formed were driven off. A fine impalpable red powder remained, which was mixed with six times its weight of equal parts of sulphur and potassium carbonate and melted in a well-covered porcelain crucible until almost all free sulphur had gone. The fused mass was lixiviated with hot water, the filtrate, acidulated with nitric acid, mixed, after having been heated for some time, with an excess of potassium carbonate, heated again, evaporated to dryness and fused, gave a dark bluish green mass, due to the presence of potassium manganate. The intensity of the colour showed that the amount of manganese present was not inconsiderable.—J. T.

The Escape of Dissolved Bodies on the Evaporation of their Solvent. P. Marguerite-Delacharlonny. Compt. Rend. **10**, 1128.

The author proved by means of direct experiments that on evaporating solutions, even at common temperatures, traces of the dissolved matter are carried away with the vapours of the solvent. Aqueous solutions of sulphuric acid, sodium hydrate, sodium carbonate and ferrous sulphate were placed in shallow dishes and covered with inverted funnels, in the stems of which strips of litmus and potassium sulphocyanide paper respectively were fastened. At 60° to 70° C. the test papers showed the action of the dissolved matter after two or three hours, whereas at common temperatures the papers were not visibly affected until after two or three days. Strips moistened with potassium ferrocyanide and suspended over an acid ferrous sulphate solution were blued after a few days.—S. H.

New Method for Detecting Cinchona Alkaloids in Quinine Sulphate. E. Goebel. Brit. and Col. Druggist, March 12, 1887.

0·5grm. quinine sulphate is boiled with 10grms. water, 0·15grm. potassium chromate added, the mixture thoroughly stirred and then allowed to stand for four hours. The quinine separates completely as chromate; this is then filtered off and one drop of caustic potash solution added to the filtrate. The presence of 0·5 per cent. cinchonine, or of 1 per cent. quinidine or cinchonidine, produces a flocculent precipitate after standing half-an-hour; with larger quantities a turbidity ensues at once. The degree of turbidity serves as a guide to the quantity of foreign alkaloids present. The test may be applied to all quinine salts, the acid salts being first evaporated down with ammonia.—C. A. K.

New Colour Reactions of Starch and Gum. A. Ihl. Chem. Zeit. **11**, 19.

Phenols and sulphuric or hydrochloric acid give with carbohydrates brilliant colour reactions. If starch be moistened on a watch-glass with an alcoholic α-naphthol solution and a few drops of warm sulphuric acid added, the starch is coloured red-violet. Thymol, cresol, guaiacol and catechol produce a splendid vermilion-red; resorcinol and orcinol yellow-red, whereas phloroglucinol gives a yellow-brown colouration. The different kinds of gum behave on the whole like starch. The action of phloroglucinol on arabin is very characteristic. If arabin be boiled with an alcoholic solution of phloroglucinol and hydrochloric acid, a fine cherry-red dyestuff is obtained.—S. H.

Analysis of Fats. B. Röse. Rep. Anal. Chem. **6**, 685—695.

After pointing out the inaccuracies in some of the processes in common use, the author criticises at some length the gravimetric processes of Oudemans and Kremel, both of whom separate the solid from the liquid portions of a fat by treatment with ether, after saponification with lead, the lead soaps made from the liquid fats being soluble in ether, whereas those made from solid fats are insoluble. The results obtained by both processes are very liable to error, *firstly*, owing to oxidation, especially of the fatty acids of the linoleic series, during the operations. The products of oxidation being partly insoluble in ether, the undissolved matter would not merely consist of the lead soaps of the solid fats, but also of the lead compounds of the oxidised liquid fats. During the evaporation and drying of the filtrate, after extraction with ether, further oxidation takes place, thus *increasing* at this stage the apparent amount of the liquid fat. *Secondly*, during the digestion of the lead soaps with boiling ether, the excess of lead oxide tends to form basic compounds with the liquid fats, and these being insoluble in ether, the result is a still further increase in the apparent amount of solid fat, found by calculation from the weight of insoluble lead soaps. Further, on decomposing this lead soap with acid, the melting point of the resulting fatty acids will be too low, owing to the presence of the small quantity of liquid fatty acids introduced by the above defects in the process. The author overcomes these defects in the following manner:—In preparing the fatty acids from the fat, great care must be taken to avoid oxidation. The fat is saponified with an alcoholic solution of potash, decomposed with sulphuric acid, cooled, and the liquid with the solid fatty acids transferred to a graduated tube, in which it is shaken up with an equal volume of ether. When clear, the amount of fatty acid is determined in a portion of the ethereal solution on evaporation, the residue being dried in a current of dry carbonic acid, before weighing. A definite volume of the ethereal solution, corresponding to about 1grm. of fatty acid, is then transferred to a 100cc. flask, with an excess of lead oxide, diluted to about 80cc. with ether, and then allowed to stand *in a cool place* until the solution becomes strongly alkaline, which will require 2 to 4 days, with occasional shaking. The liquid is made up with ether to exactly 100cc.; 50cc. are passed through a small filter, into a tared flask, the filter being kept full as long as possible, and then evaporated to dryness, *out of contact with air*. After weighing, the lead is determined in the residue as lead sulphate. The trial experiments given in detail by the author, are exceedingly accurate. Working with 1grm. of pure oleic acid, he obtained as the mean of five closely-agreeing results, 1·3613grms. lead oleate, and 0·5358grm. of lead sulphate, instead of the theoretical amounts, 1·3617 and 0·5358grms. respectively. The figures obtained with stearic acid and mixtures of known composition were equally satisfactory; but it is recommended to check the results with the iodine process, using in the latter, fatty acids instead of the original glycerides.—E. E. B.

Trade Report.

(From the Board of Trade Journal.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

BELGIUM.

Modifications in Duties on Vinegar and Acetic Acid.

The following is a translation of a decree, dated the 24th March last, which appeared in the *Moniteur Belge* of the day following, provisionally modifying the import duties on vinegar and acetic acid:—

"Article 1.—Vinegar and acetic acid will pay import duties as follows:—Vinegars, acetic acids, and liquids containing pure acetic acid to the extent of 8 per cent. or less, 15frs. per hectolitre; more than 8 per cent. and less than 50 per cent., 75frs. per hectolitre; 50 per cent., or more, 120frs. per hectolitre. Acetic acid, crystallised, of 150frs. per 100 kilos.

"Article 2.—The present tariff of import duties on articles mentioned in Article 1 will be substituted for the above by the 1st July, 1887, at the latest, if, before that date, the existing duties on the said goods have not been definitely modified by law.

"Article 3.—The difference between the duties collected by the application of this decree and the duties which would be leviable under the existing tariff, until the 1st July, 1887, will be refunded if the duties as stated in Article 2 be not modified by law.

"Article 4.—The present decree will come into force on the day following its publication."

SWITZERLAND.

Classification of Articles in Customs Tariff.

(*Note.*—Quintal = 220·4lb. avoirdupois. Franc = $9\frac{5}{8}$d.)

The following decisions affecting the classification of articles in the Swiss Customs Tariff have been given by the Swiss Customs authorities during the month of February last:—

Bi-phosphate of lime, in bottles, without labels claiming for the article any curative properties, is included in Category 9, and pays a duty of 10 francs per quintal.

Bi-phosphate of lime, with labels attributing to it curative properties. Categories 11 and 12, duties as follows:—In wholesale packages, 10 francs per quintal, in retail packages, 100 francs per quintal.

Nitro naphthaline. Category 18, duty 2 francs per quintal.

Dextrine will in future pay a duty of 1 franc per quintal under Category 17.

UNITED STATES.

Customs Decisions.

"Tungsten-metal," which is a substance in the nature of an alloy obtained from wolframite ore, which contains principally the metal, tungsten, and several other metals in various small proportions, and which is imported and used for the purpose of being added in small quantities to steel or iron in order to render the latter metals suitable for the manufacture of tools, is not one of the substitutes for steel contemplated by the provision in section 177, but is dutiable at the rate of 20 per cent. *ad valorem* as an unwrought metal not otherwise provided for under the provisions in the same section for "metals unwrought."

Deductions for non-dutiable charges cannot be allowed in cases where they are included in the invoice or entry in the same item with dutiable charges.

"Doctor Liebreich's Lanoline," which, upon investigation, is found to be a rendered oil, and not an ointment or medicinal preparation, is held to be dutiable at the rate of 25 per cent. *ad valorem*, as a rendered oil, under section 92.

Certain "chlor-magnesium," or chloride of magnesium, which, upon analysis, was found to contain chlorine and magnesium in combination, is held to be dutiable at the rate of 25 per cent. *ad valorem*, under the provision in section 92 for "all chemical compounds and salts, by whatever name known, and not specially enumerated or provided for in this Act."

MEXICO.

Modifications in Customs Tariff.

According to the *Moniteur Belge* for the 25th March last, the following articles have been exempted from payment of import duties, by a decree of the President of the Republic, dated the 25th February last :—

Phenic acid, sulphuric acid, hydrochloric acid, chloride of lime, permanganate of potassium, sulphate of copper, and sulphate of iron.

GREECE.

Modifications in Customs Tariff.

A despatch, dated the 12th March last, has been received from Sir H. Rumbold, Her Majesty's Minister at Athens, enclosing a table showing certain modifications in the Greek Customs Tariff, which were to come into operation on the 13th March last, subject to subsequent ratification by the Chamber. The following is the statement of the modifications in question :—

(*Note.*—Drachme = $9\frac{4}{5}$d. Oke = 2·8lb. avoirdupois. Drachme (weight) = 0·111oz. avoirdupois.)

MISCELLANEOUS TRADE NOTICES.

INTERNATIONAL COMPETITION OF SCIENCE AND INDUSTRY AT BRUSSELS IN 1888.

The *Moniteur Belge* for the 16th March last says :—

"The organisers of the International Competition of Science and Industry which will be opened in Brussels in 1888, have applied to the Government for assistance. Already a numerous commission, consisting of all the scientific, art, and industrial authorities, have been appointed to conduct the exhibition, and to induce Belgian producers to participate in this international work. The international import and export exhibition attached to the great exhibition will include a section devoted specially to colonial countries, but principally to the Congo."

A royal decree, appointing the jurors to the several sections of the exhibition, was published in the *Moniteur Belge* for the same date.

PETROLEUM RESERVOIR AT ROTTERDAM.

The *Bulletin du Musée Commercial* of the 8th January last says, that an immense iron reservoir is now being constructed at Rotterdam, which is to be used for storage of petroleum.

It will be sufficiently large to hold 7,900,000 litres of petroleum. Mineral oil will, on arrival, be transferred to the reservoir by means of pumps, thus obviating the necessity for the employment of casks and barrels, and considerably diminishing the expenses, and lessening the risk of accidents.

Commercial Museum at Bucharest.

The *Curierul Financiar* of the 13th February last informs its readers that M. Jean Bratiano has laid before the Roumanian Chambers a proposal to erect at Bucharest a permanent exhibition of the agricultural and industrial products of the country. The capital required for the construction and furnishing of this museum is about 1,200,000 francs. The object of this institution is to afford Roumanian merchants and manufacturers a knowledge of the resources and requirements of foreign markets, and to show the foreign purchaser the resources of Roumanian industry, by exhibiting samples of the principal industrial products of the country, so that he may be enabled to place his orders without visiting the various manufactories scattered throughout the kingdom. All information is to be given gratis, and a commission will be paid by agriculturists and manufacturers who obtain orders through the intermediary of this institution.

Commercial Museum at Buenos Ayres.

According to the *Journal Officiel* of the 11th March last, a Commercial Museum of articles of foreign produce has been opened by the Italian Chamber of Commerce at Buenos Ayres.

New Paper-making Invention in Japan.

According to the *Bulletin du Musee Commercial* of the 22nd January last, a native of Japan has recently invented a new process by which paper may be manufactured with seaweed. Paper made in this way is very strong, almost untearable, and is sufficiently transparent to admit of its being used as window glass; it takes all colours well, and in many respects resembles old window glass.

Registration of Trade Marks in Germany.

The German Imperial Supreme Court, sitting at Leipzic, has just pronounced judgment on a point of considerable importance to English and other foreign manufacturers and merchants who have no branch in Germany. It is decided that such houses can have their trade marks registered by the competent authority at Leipzic, even although they consist exclusively of numbers, letters, or words, which are not recognised as trade marks for purely German houses.—*Brit. and Col. Drug.*

The German Glass Industry.

Despite Belgian competition, the German glass industry is making steady progress. There is increasing activity in some branches, and a fair prospect of a good year's trade. Larger orders are being received from the United States and from England. The demand is chiefly for the cheaper sorts, the foreign trade in bottle glass being especially brisk. The total exports of glass from Germany last year amounted to 1,596,380cwt., against 1,547,360cwt. in 1885. The British export trade in glass, other than plate and mirrors, amounted in 1886 to 1,101,396cwt.—*Brit. and Col. Drug.*

American Sodium Bicarbonate.

The New York *Pharm. Rundschau* says that Dr. F. B. Power has recently examined five American and one German brand of sodium bicarbonate, more especially to note whether they contained any sodium thiosulphate (hyposulphite) and arsenic. Both these impurities have been asserted to be present in English and some of the German brands, but in the brands examined they were absent. A trace of sulphite was found in two samples; three of the brands contained but traces of normal carbonate; the other three samples contained less than 3 per cent. of normal carbonate. Of the American brands the Natrona and Dwight's ranked above the others.

Trade Statistics for March.

The Board of Trade Returns for March show the following figures :—

Imports.

	March, 1886.		March, 1887.
Total value	£31,490,937	....	£32,791,930

Exports.

	March, 1886.		March, 1887.
British and Irish Produce	£18,510,072	....	£19,002,083
Foreign and Colonial Produce (partly estimated)	1,631,796	....	5,076,379

Opposite are the details affecting drugs and chemicals :—

Messrs. Gehe & Co., of Dresden, in the preface to their half-yearly review of the drug and chemical markets, briefly refer to the proposals which have been made in several continental countries for the creation of a state monopoly in alcohol, a scheme which would, of course, greatly affect the pharmaceutical and chemical industries. The first country which will now be called upon to give a decision regarding the alcohol monopoly proposal is Switzerland, which produces a moderate amount of spirits only, and in which the scheme would therefore principally affect the importation of spirits from abroad. In France a strong agitation is also carried on in favour of a monopoly scheme, while in Germany it is certain that the Government intend to again bring forward a bill on the subject, as a means of increasing the revenue, though the details of the proposed measure have not as yet taken any practical form. Alcohol being an important article of export from Germany, although one which at present leaves no profit to the exporters, it is probable that a large part of the revenue derived from a monopoly would be absorbed by the export trade in the shape of bounties. In the interests of the pharmaceutical and chemical industries it is hoped that, under a state monopoly, the increase in duty on alcohol required in these branches of industry will be confined to the narrowest limits, and that no vexatious regulations for the control of manufacturers will be laid down, as otherwise it is feared that German firms will not be able to continue to compete with foreign rivals.—*Chemist and Druggist.*

The Report of the Belgian Commission to inquire into the condition of the industrial classes in that country, has been issued, and an abstract thereof will be found in the *Board of Trade Journal*—April, 1887—p. 316.

The text of the new French Butter and Oleomargine Law appears on page 350 of the *Board of Trade Journal* for April, 1887.

RECENT TRADE BLUE BOOKS.

(C—4968) Price 8½d. See *Board of Trade Journal* for April, p. 358.

Patent Office Inquiry. Report of the Committee appointed by the Board of Trade to inquire into the duties, organisation, and arrangements of the Patent Office under the Patents, Designs and Trade Marks Act, 1883, having special regard to the system of examination of the specifications which accompany applications for patents now in force under that Act, together with minutes of evidence, appendices, etc.

FOREIGN TRADE OF INDIA.

During the ten months (April 1 to January 31) just past, British India imported chemicals (including drugs, medicines, narcotics, and dyeing and tanning materials) to the value of 76,92,315 rupees as against 72,18,197 rupees for the corresponding period of 1885—1886. The exports under the same heading and for the same period amounted to 12,72,68,188 rupees as against 12,82,22,412 rupees during 1885—1886.

Monthly Patent List.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

4168 J. H. Johnson—From F. Romain, France. Apparatus for raising and forcing liquids and obtaining motive power. Complete specification. March 19

4185 R. Thompson, London. Improvements relating to stop-cocks and stop-valves. March 19

4190 H. Gonne, London. Freezing and refrigerating apparatus. March 19

4207 J. Hall, Manchester. Steam jet condensers. March 21

4245 E. Bennis, E. Bennis, and A. W. Bennis, Liverpool. Improvements in boiler furnaces and in apparatus for conveying or feeding fuel thereto. March 22

4248 H. Holden and R. G. Brooke, Salford. Back-pressure valves. March 22

4326 W. A. Ross, Belfast. Apparatus for automatically obtaining and employing artificial currents of air. March 23

4338 J. B. Hannay and A. Murray. Air or gas compressors or pumps. March 23

4362 W. Gaskell, London. Apparatus for preventing smoke and economising fuel in steam-boiler furnaces. March 23

4425 H. E. Newton—From W. Baur, United States. Improvements in filter-presses. Complete specification. March 24

4439 G. Wilton, Silvertown. Improvements in the arrangements of furnaces and appliances where hydrocarbon oils together with water or steam, coal, or breeze, are used as fuel, March 25

4455 D. M. Salmond, Bradford. An improved composition for preventing and removing incrustation in steam boilers. March 25

4543 H. Moon, London. Improvements in amalgamating apparatus. March 26

4571 F. Friedenthal, Preston. Furnaces of steam-generators with forced draught for burning small fuel or fuel dust. March 28

4600 C. F. Dahl, London. An improved furnace for recovering in an inodorous manner the salts contained in the lyes used in the manufacture of wood fibre. Complete specification. March 28

4601 R. Marshall, London. Improvements in steam-boiler and other furnaces. March 28

4626 C. A. Koellner, London. Improvements in filter pumps. Complete specification. March 28

4653 J. J. Butcher, Newcastle-on-Tyne. Apparatus for increasing and controlling the pressure of coal or other gas. March 29

4651 G. S. Hendry and A. Faulds, Glasgow. Improvements in apparatus or hydraulic air-compressing engines for raising liquids. March 29

4685 E. W. Van Duzen, London. Improvements in furnaces and grate bars therefor. Complete specification. March 29

4699 W. Von Oechelhaeuser, London. Apparatus for regulating the flow of gas and other fluids. March 29

4749 A. M. Clark—From P. Orielle, jun., France. Means for preventing the emission of flame and smoke from the chimneys of furnaces working with a forced draught. March 30

4780 R. Matthews, London. Apparatus for refrigerating, or producing and utilising cold. March 30

4976 J. V. Wilson, Manchester. Improvements in or applicable to pans for heating oil or other liquids, and in apparatus for passing air or gases through liquids, and agitating liquids in pans and similar vessels. Complete specification. April 4

4989 D. Simpson, Edinburgh. See Class VII.

5161 J. W. Hartley, Stoke-on-Trent. Improvements in smoke consuming apparatus. April 7

5165 J. Davies, Manchester. Improvements in kiln and other furnaces. April 7

5235 F. W. Beck, East Grinstead. A damp detector and hygrometer. April 9

5255 W. D. Priestman and S. Priestman, London. Improvements in the manufacture of vapour and in apparatus therefor. April 9

5379 J. R. Alsing, London. Improvements in the construction of triturating cylinders. April 13

5411 W. D. Player and T. Dustman, London. New or improved apparatus for facilitating the removal of scale or incrustation from steam-boilers and other steam generators. April 11

5169 A. Dickinson, Birmingham. Improvements in condensers. April 15

*COMPLETE SPECIFICATIONS ACCEPTED.**

1886.

5618 R. Matthews. Apparatus for refrigerating, and for utilising cold. April 2

6792 F. Hilton. Open hearth furnaces. March 23

6801 R. W. Hitchins. Compound for preventing the radiation and transmission of heat. March 23

7015 J. B. Alliott and J. M. C. Paton. Filter presses and apparatus connected therewith. March 30

---

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

7088 G. F. Marshall. Improvements in filters. March 30

7119 W. T Sugg. Apparatus for heating water, etc. March 30

7180 G. Fulda. An improved valve-cock. March 26

7761 J. Allison and A. Thomson. Furnace fittings for use with forced draught. April 2

7768 A. Paget. Taps for gas and other fluids. April 16

8201 C Langer. Apparatus for mixing, stirring, and conveying various substances, and for drying and exposing the same to the chemical action of gases, vapours, etc. April 20

1887.

761 G. D. Hughes and D. Hughes. A furnace bar and smoke-consuming furnace. April 16

2710 J. A. Crocker. Filtering machines. March 23

2711 J. A. Crocker. Filtering machines. March 23

2881 B. J. B. Mills—From J. Retif. Filter for water and other liquids. March 26

3016 R. R. Evans. Centrifugal pumps and fans for blast and exhaust purposes. March 30

3388 A. Lentz. Charging retorts, and apparatus therefor. April 16

3999 E. Albin. Heating air and feeding the same to boiler furnaces, etc. April 20

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

1315 E. Entwistle, Blackburn. Apparatus to economise and improve the consumption of fuel and smoke in open or closed grates or furnaces, also regulating the draught or air current. March 23

1381 R. Auton, London. Improvements in manufacturing briquettes or blocks of artificial fuel or bricks or blocks of other material, and in machinery therefor. March 23

1139 G. Wilton. See Class I.

4187 W. H. Lindsay, London. Improvements in the utilisation of breeze dust and cinder waste, more especially the dust or waste collected from dwelling houses. March 25

1653 J. J. Butcher. See Class I.

4687 A. A. Harwood and M. D. Van Tassel, London. An improved apparatus for generating gas. Complete specification. March 29

4722 W. Wright and F. W. Wright, Manchester. Improvements in lighting. March 30

4751 E. Davies, London. Improvement in lighting. March 30

4810 G. H. Elphick, London. A new or improved appliance for preventing the guttering or wasting of candles. March 31

4859 A. Fehlen, London. Improvements in the methods of turning to account combustibility for heating purposes. April 1

4881 W. Majert and G. Richter, London. A process and apparatus for the production of hydrogen gas by a dry method, for military purposes. April 1

4884 G. F. Redfern—From A. Goutierre, Belgium. Improvements in and apparatus for the manufacture of gas for lighting, heating, or other purposes. April 1

4886 J. Wybauw, London. Improvements in apparatus for lighting and heating by means of gas. April 1

4888 F. Friedlander and J. Quaglis, London. Improvements in obtaining hydrocarbons from gases. Complete specification. April 1

4918 R. Haddon—From J. J. Imbs, France. A process for utilising the heat of the exhaust steam or gases of steam or other engines. April 2

5012 G. F. Redfern—From A. Robert, Belgium. Improvements in machinery or apparatus for the manufacture of artificial fuel. April 4

5026 W. G. Bussey, London. Improvements in apparatus for vaporising and burning liquid hydrocarbons. Complete specification. April 5

5035 H. Jefferies, Stourport. An improved apparatus or valve used in the manufacture of coal and other gases or for other similar purposes. April 5

5046 J. M. A. Fournier, London. An improved appliance for purifying heating and illuminating gas. April 5

5287 H. J. Newcome, Shenley. Rapidly obtaining the utmost degree of warmth from petroleum burnt in an open vessel placed in a close stove. April 12

5313 H. Cockey and F. C. Cockey, Westminster. Improvements in gas washers. Complete specification. April 12

5473 J. Laidler, Sunderland. Improvements for the manufacturing of every description of compressed fuel whatsoever. April 15

5474 J. Laidler. A machine for the manufacturing of every description of compressed fuel whatsoever. April 15

5481 R. Scott, Newcastle-on-Tyne. Improvements in the media and construction of globes for increasing the luminosity of light. April 15

5530 A. Harris, London. Improvements in gas producers. April 15

5571 W. W. Horn, London—From A. L. Allen, United States. Improvements in apparatus for the manufacture of gas. April 16

5638 G. E. Dorman, Stafford. Improved construction of thermopiles heated directly by the combustion of fuel, or by heated gases. April 18

5641 J. Broad, J. W. Broad, G. P. Broad, H. J. Broad, and G. C. Fowler, London. Improvements in night-lights. April 18

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

5727 T. Nicholson. Methods and appliances for obtaining, and cleansing, gas from coal. March 26

6858 A. J. Boult—From A. Montenegro. Method of heating apartments. March 23

7112 W. S. Sutherland. Improvements in gas producers. March 30

7228 E. J. Barnfield. Gas-retort furnaces. March 30

7258 R. Good. Hydraulic mains for gas works. March 30

7365 A. Paget. Manufacture of matters for incandescent gas-lighting. March 30

7705 J. Bartle. Adjusting and locking the handles of gas-retort covers or lids. April 9

7706 H. Cockey and F. C. Cockey. Gas purifier centre-valves. April 9

8157 O. Imray—From F. Siemens. Regenerative gas-retort furnaces. April 20

9047 J. Blum. The instantaneous generation of steam. April 2

10969 A. Brin and L. Q. Brinn. Means for heating steam boilers, etc., and for decomposing steam and burning its constituent gases for the production of light and heat. March 26

13214 P. Innes Hydraulic mains apparatus used in the manufacture of illuminating gas. March 26

1887.

2749 A. J. Boult—From W. H. Brooks. Manufacture of steam and oil gas for fuel and for illuminating purposes. March 23

2752 H. J. Seibel, jun. Apparatus for enriching gas. March 23

3999 E. Albin—See Class I.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, ETC.

APPLICATION.

5519 J. Elliott, Westminster. Improvements in gas apparatus for effecting the continuous carbonisation of coal. April 15

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

4243 W. Majert, London. Improvements in and relating to the manufacture of colouring matters. March 21

4481 C. D. Abel—From O. Korschelt, Germany. An improved manufacture of logwood extract. March 25

4492 H. H. Lake—From K. Oehler, Germany. Improvements in the manufacture of colouring matters. March 25

4583 R. H. W. Biggs, London. Improvements in the manufacture of dyes, disinfectants, artificial stone, artificial ivory, artificial manure, sodium, and other substances. March 28

5049 S. J. Simpkin, London. Improvements in or relating to the manufacture of pure or refined indigo. April 5

5109 J. Hauff, Manchester. Producing basic sulphocyanides of aluminium, iron, and chromium for dyeing and printing purposes. April 6

5257 C. D. Abel—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Improvements in the production of dialkylised amidobenzophenones. April 9

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

4387 H. H. Lake—From A. Leonardt and Co. The manufacture of colouring matters. March 26

7137 C. D. Abel—From The Farbwerke vormals Meister, Lucius, and Brüning. Production of indoderivatives from the compounds of the aromatic hydrazines with the ketones and the aldehydes. March 30

12022 A. Kern. Improvements relating to substances chiefly designed for use in the preparation of colouring matters, and to the manufacture of colouring matters therefrom. April 20

1887.

2123 H. H. Lake—From L. Whitefield. Compound for producing designs upon textile fabrics. March 23

V.—TEXTILES, COTTON, WOOL, SILK, ETC.

APPLICATIONS.

4981 D. Smith and H. Smith, Bradford. Improvements in the method of and apparatus for washing wool and other fibres. April 1

5011 W. B. Nation and J. J. Worswick, London. Improvements in the treatment of vegetable fibres suitable for spinning, weaving, and other analogous purposes. April 5

5097 R. H. Collyer, London. Improved machinery and apparatus for the preparation of vegetable fibres for textile purposes. April 6

5205 H. H. Lake—From La Société Gillet et fils, France. Improvements relating to the treatment of fabrics composed of or containing silk for improving the appearance of the same. April 7

5315 N. Dubois-Mauduit, London. An improved process for rendering woven fabrics waterproof. April 12

5577 H. H. Lake—From E. Brown, United States. The manufacture of an improved textile fabric and apparatus therefor. April 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

7530 E. de Pass—From La Société de Lafarge, Lebre et Cie. See Class XIX.

7927 A. M. Clark—From L. P. Audouard. Treating woven and other fabrics, yarns, ropes, etc., to render same non-putrefactive and antiseptic. April 20

16765 J. H. Lorimer. Drying, bleaching, and disinfecting wool, cotton, paper pulp, or other textile or fibrous materials, and apparatus therefor. March 30

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

4289 W. G. Young, London. An improved mordant for dyeing cotton and other fibrous substances a fast black. March 22

4365 E. Booth, London—From W. A. Fourness, Belgium. Improvements in apparatus for dyeing loose or spun cotton or other fibres. Complete specification. March 23

4509 E. Sutcliffe, G. E. Sutcliffe, and the Patent Process Dyeing Co., Limited, Manchester. Improvements in the method of, and in apparatus for, washing, bleaching, dyeing, and treating textile materials. March 26

4517 R. Chadwick and J. W. C. Chadwick, London. Improvements in dyeing yarns and fabrics black, blue, and other colours. March 26

4764 G. Jugenburg, London. An improved mode of and apparatus for mordanting, dyeing, and bleaching raw cotton. Complete specification. March 30

4905 A. Ferrie, Manchester. Improvements in dyeing and printing blacks, blues, browns, and other dark colours upon animal and vegetable matters. April 2

4953 A. Brin and L. Q. Brin, Westminster. Improvements in bleaching fibrous substances used for making paper. April 2

5113 D. Stewart and R. Walker, Glasgow. Improvements in apparatus for stretching and airing, liquoring, soaping, or washing woven fabrics. April 6

5150 J. McNaught and W. McNaught, jun., London. Improvements in or applicable to machinery for scouring and washing wool and other fibrous materials. April 6

5166 J. Davies, Manchester. Improvements in aniline dyeing. April 7

5175 R. Gledhill, Bradford. Improvements in dyeing apparatus connected with machines for sizing worsted or other warps April 7

5212 A. Goldthorp, Wakefield. An improved form of rod or stick, and apparatus connected therewith, for more evenly dyeing fibrous substances in hanks. April 9

5359 J. Gibson and F. M. Gibson, Edinburgh. Improvements in bleaching fibrous materials. April 13

5596 J. Bromley and T. Harrison, Leeds. Improvements in machinery for bronzing, colouring, or otherwise ornamenting paper and other material in sheets or continuous rolls. Complete specification. April 18

COMPLETE SPECIFICATION ACCEPTED.

1886.

8065 C. Lohmann. Improvements in dyeing blue, especially adapted for wool. April 9

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

4088 G. Milligan, Oxford. Obtaining aluminate of soda by a new process, from clay and soda salts. March 18

4133 J. Y. Johnson—From C. Dubois, France. Improvements in condensing chambers for sublimed sulphur. Complete specification. March 18

4199 A. Brin and L. Q. Brin, London. Improvements in the production of chlorine and hydrogen. March 21

4201 J. Taylor, Glasgow. Improvements in the manufacture of nitric acid. March 21

4241 H. Baum, London. Improvements in the manufacture of pyro-sulphates. March 21

4363 A. Shelmerdine, Liverpool. Improvements in the treatment and utilisation of alkali waste, known as "lime mud," for obtaining a useful product therefrom. March 23

4371 A. Delhaye, London. Improvements in the manufacture of caustic or carbonated soda and caustic potash. March 23

4430 J. Brock, Widnes—Partly communicated by G. Lunge, Switzerland. Improvements in apparatus for the manufacture of monohydrated sulphuric acid. March 24

4686 H. Gall and V. A. de Montlaur, London. Improvements in the manufacture of chlorates of the alkalies or alkaline earths. March 29

4989 D. Simpson, Edinburgh. Improvements in apparatus for concentrating liquids, and for separating salts from their solutions by evaporation. April 4

5124 G. I. J. Wells—From S. Pick, Galicia. Improvements in the evaporating of liquors containing salts, and in the separation of those salts. April 6.

5250 A. Shelmerdine, Liverpool. Improvements in the treatment and utilisation of alkali residue, known as "lime mud," for obtaining a useful product therefrom. April 9

5393 E. Hermite, London. Manufacture of bleaching and disinfecting liquor. April 13

5419 T. Thompson, Edinburgh. An improved and entirely new method for the admixture of ferrous sulphate or sulphate of iron and potassium carbonate, so that chemical action between them is prevented until exposed to each other in the presence of moisture. April 14

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

1922 C. F. Claus. Manufacture of carbonate of soda and carbonate of potash, and treatment of residues obtained thereby. March 26

5512 D. G. Fitz-Gerald. The regeneration or production of chromic acid from exhausted battery and other solutions. April 20

7137 J. Y. Johnson—From C. Dubois. Apparatus for extracting and subliming sulphur. March 30

7192 A. Fritschi. Manufacture of carbonic oxide gas. April 2

7859 B. Dawson. Apparatus for evaporating waste lyes and recovering soda from black liquor. April 16

8602 J. Park. Manufacture of bichromate of ammonia. April 16

1887.

4133 J. G. Johnson—From C. Dubois. Condensing chambers for sublimed sulphur. April 20

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

4212 M. Hoffmann, London. An improved process for manufacturing artificial majolica, delft, porcelain, and enamel. March 21

4485 A. M. Clark—From C. J. Brunetti, France. An improved process of ornamenting articles of glass, porcelain, and other ceramic or vitrifiable materials. March 25

4689 L. Preussner, London. A process for the production of marble-like or enamel-like objects. March 29

4821 E. Moore, London. Improvements in the manufacture of opaque glass of a certain new colour. Complete specification. March 31

4822 E. Moore. The manufacture of opaque glass of a new colour. Complete specification. March 31

4975 D. Rylands, Barnsley. Improvements relating to the casting and cooling of glass sleepers or other glass castings. April 4

5420 T. W. Hogg and P. J. Jackson, Newcastle-on-Tyne. An improved method for printing upon glass, porcelain, or earthenware, and apparatus therefor. April 14

5429 F. Wallbrecht, London. Improvements in the manufacture of bricks, tiles, and all kinds of earthenware. Complete specification. April 14

5560 A. D. Brogan and A. M. Malloch, Glasgow. An improved method of producing rippled, chequered, or other patterns or designs upon rolled plate and sheet glass, and apparatus therefor. April 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

5291 D. Rylands and H. Lindsay-Bucknall. Glass-melting furnaces. April 20

7214 F. Gibbons. Manufacture of ceramic tesseræ, mosaic, tiles, seggars, etc., and apparatus therefor. March 30

8061 A. Feldmann. Production of fireproof articles of enamel. March 26

8526 J. R. Windmill. Making glass bottles, jars, etc., and apparatus therefor. April 16

9015 W. H. Jones, B. Jones, W. H. Jones, and B. H. Jones. Apparatus for use in the manufacture of enamel ware. Apl. 16

15579 H. J. Allison—From C. C. Gilman. Manufacture of porous earthenware. April 16

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

4151 J. M. Robertson, Glasgow. Fireproof floors and ceilings. March 19

4278 W. Corbould. See Class XII.

4370 C. Brann and E. W. Jones, London. An improved mode of treating the slag or scoria from blast furnaces for making blocks or slabs for paving or other purposes. March 23

4394 J. W. Stansfield, Manchester. Improvements in waterproof asphalting. March 21

4606 A. J. Boult, London—From J. X. Jorda, Spain. Improvements in paving. March 28

4615 R. Haddan—From E. Clerici, Italy. An improved brick or block to be used as building material. March 28

4634 T. C. Fawcett, Halifax. Improvements in machinery for working and pressing bricks, tiles, and other articles. March 29

5152 G. F. H. Clark and R. J. Clark, London. The manufacture of a cement or composition for fastening wood, linoleum, or other covering to iron or steel decks, wood flooring, etc.; applicable also for other purposes. April 6

5155 J. W. Hooton, London. Improvements in the manufacture of Portland cement, and apparatus therefor; applicable also for other purposes. April 6

5476 D. Burns, Carlisle. Improvements in the utilisation of waste products and manufacture of bricks, tiles, and other articles therefrom. April 15

5515 J. Steele, Liverpool. Improvements in celluloid attachment for glasses. Complete specification. April 15

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

8120 S. Lowdon. Manufacture of Portland cement. April 20

15965 C. J. Dodds. Construction of paving with moulded slag blocks. March 30

1887.

979 W. E. Gedge—From J. Thorraud, V. Nicolet, and A. Bonnet. A novel artificial cement. March 30

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

4086 R. Murray, Glasgow. A method of producing sound copper castings in sand or loam moulds. March 18

4170 F. Berry, Sheffield. Apparatus and appliances for automatically revolving heavy masses of material during the process of manufacture, as in the manipulation of forgings under steam hammers, forging presses, and the like. Mar. 19

4191 J. Lysaght, Limited, W. R. Lysaght, and J. Lakin, London. Improvements in rolling very thin gauges of iron and steel sheets. March 21

4218 W. Hope. Improvements in treating hollow cylinders or shafts of steel or other metal. March 21

4228 C. Netto, London. Improvements relating to the extraction of aluminium from substances containing the same. March 21

4233 J. W. Chenhall and J. Richardson, London. An improved method of constructing machines for breaking and crushing quartz or other hard materials. March 21

4234 J. W. Chenhall and J. Richardson. Improvements in machinery for concentrating ores. March 21

4247 T. Taberner and J. Hart, Liverpool. Improvements in safety lamps for mining and other purposes. March 22

4260 W. S. Sutherland, Liverpool. Improvements in heating, mainly for welding, and in furnaces therefor. March 22

4297 G. B. Nicoll, London. A new or improved method of heating metal forgings or castings for the purpose of expanding them, with a view to their subsequent contraction upon their seats. March 22

4318 P. J. Dowling and J. F. Dowling, London. Improvements in the method of weaving tinned steel or other wire for various uses. March 23

4389 G. J. Snelus, London. Improvements relating to the treatment of furnace slag, and to apparatus therefor. Mar. 23

4434 J. E. T. Wood, London. Treating and separating refuse metals. March 24

4472 S. P. Thompson. See Class XVIII.

4512 T. Marshall, London. Improvements in miners' safety lamps. March 26

4528 H. F. Taylor and W. P. Struve, London. Improvements in the method of finishing metal plates coated with tin or other metal or alloy, and in apparatus connected therewith. Mar. 26

4531 C. Tod, London. Improvements in pulverising gold quartz. March 26

4576 D. G. Reillon, S. T. Montague, and O. L. B. L. Bourgerol, Paris. Process for extracting aluminium from alumina. Complete specification. March 28

4584 R. H. W. Biggs, London. Extracting tin from iron or tin scraps. March 28

4609 J. C. Newbery and C. T. J. Vautin, London. Improvements in the wet or hydro-metallurgical method of extracting gold from crushed or other finely divided auriferous material. Complete specification. March 28

4661 W. P. Thompson. See Class XVIII.

4846 A. Gutensohn and E. Cox, London. Improvements in the process of coating iron or other metals with tin or other metal by the use of grease. March 31

4887 T. Bower, R. W. Bower, and J. Blackburn, London. An improved means for detaching or forcing down coal or other minerals. April 1

4993 W. H. Rickard and T. J. Rickard, Newport, Mon. Improvements in the method of, and apparatus or machinery for, coating plates with tin, lead, or other metal or alloys of the same. April 4

5002 E. Morris, London. Improvements in the method of, and apparatus to be employed in connection with, lime blasting operations in mines. April 4

5029 R. Hannan and M. Milburn, Glasgow. Improvements in obtaining zinc from its blende or sulphide. April 5

5399 G. W. Elliott, Sheffield. Improvements in wedges for winning coal, rock, and other minerals. April 11

5411 F. Herbert and C. G. Gordon, Newport, Mon. Improvements in "Bessemer" and other ingot moulds. April 14

5470 P. F. Kendall, Manchester. The determination of the direction of the dip of rocks in deep bore holes, and of the direction of deviation of boring from the perpendicular. April 15

5501 A. L. Keeport, London. Improvements in the process of obtaining the oxides, etc., of metals from their ores or from crude minerals. Complete specification. April 15

5622 W. H. Rickard and T. J. Rickard, London. Improvements in the method of, and apparatus or machinery for, coating plates with tin, lead and other metal, or alloys of the same. April 18

5627 A. Woodhouse, London. Improvement in apparatus for the amalgamation of gold. April 18

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

5832 J. Y. Johnson—From La Société Anonyme Le Ferro-Nickel. Manufacture of alloys of nickel, copper and aluminium. April 2

6747 A. M. Clark—From La Societe Anonyme de Produits Chimiques de St. Denis. Process and apparatus for treatment of iron ores for the manufacture of steel. March 23

6786 J. Thomas, H. Lewis, E. W. Lewis, and T. L. Thomas. Method and apparatus for galvanising sheet metal. March 23

6803 E. Edwards—From M. Ramos-Garcia. Separation of metallic tin from tinned plates, or from alloys or salts of tin. April 9

6810 J. Noad. Extraction of gold, silver, and platinum from ores and other substances. March 23

6974 E. Hunt—From G. Thomson. Obtaining copper from solutions of its salts. March 23

6977 C. J. Sandahl, G. Bargate, and C. B. Phillips. Manufacture of ferro-manganese, silico-spiegel, spiegelisen, and chrome iron. March 26

7008 W. Evans. Heating furnace for steel sleepers, etc., and apparatus connected therewith. March 26

7081 C. T. Cayley. Dies for use in the manufacture of rolled metal articles. March 30

7089 G. F. Redfern—From J. M. N. Millot. Compressing sand cores and moulds used in the manufacture of cast-metal pipes, and apparatus therefor. March 30

7191 A. Fritschi. Smelting iron and other metallic ores, and apparatus therefor. March 30

7777 W. Briggs. Preserving iron and steel structures from oxidation. April 9

8130 J. Noad. Extraction of gold, silver, and copper from ores, etc. March 23

8324 A. Gutensohn and J. M. James. Pickling or cleaning the surface of iron or other metal previous to coating it with tin or other metal. April 16

8359 T. Twynam. Refractory linings specially adapted for metallurgical furnaces, but applicable also for other purposes. April 20

8121 A. R. Ormiston and J. Ormiston. Processes and apparatus for testing miners' safety lamps. April 16

8881 P. M. Justice—From H. T. Rode. Manufacture of steel and ingot iron. April 16

9008 A. E. Stayner. Drilling machines for rock and coal. April 16

9015 W. H. Jones, B. Jones, W. H. Jones, and B. H. Jones. Apparatus for use in manufacture of enamel ware. April 16

10753 R. Schneider. Separating funnels or gits used for making perfectly solid and pure castings of iron, steel, etc. April 16

12053 D. McKechnie. Method and apparatus for smelting or refining copper. March 23

14982 C. W. Thompson. Rock drills. April 20

16935 E. de Pass—From La Société Industrielle et Commerciale des Métaux. Preserving the surface of copper or its alloys. April 16

1887.

2740 M. Constable and J. R. Bingle. Extraction of gold, silver, and other metals from ferriferous ores. March 23

2774 A. E. Outerbridge, jun. Moulds for metal castings. March 23

3738 P. M. Justice—From H. T. Rode. Manufacture of steel and ingot iron. April 16

XI.—FATS, OILS, and SOAP MANUFACTURE.

APPLICATIONS.

5132 W. P. Thompson—From La Société Industrielle de Glycerine et Acides Gras, Paris. Improved process for the continuous distillation of fatty bodies. April 14

5133 W. P. Thompson, Liverpool. Improvements in the manufacture or treating of cotton-seed oil and other products from cotton-seed, cotton-seed oil, or its residues. April 14

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

5277 H. Lambert and G. Greenwood. Apparatus for expressing oil from oil-yielding vegetable substances, and converting the residue into oil cake. April 16

6981 R. Jaques. Improvements in toilet soap tablets. March 26

10968 A. Brin and L. Q. Brin. Means for bleaching and disinfecting animal, vegetable, or mineral oils and fatty matters. March 26

12652 A. Brin and L. Q. Brin. Oxidation of oils for use in the manufacture of paints or varnishes, and for other purposes. March 26

1887.

2615 W. Buttner, J. G. Haller, and J. Magnus. Apparatus and means for extracting, washing and condensing fat, grease, glue, oil, or other substances from bones, wool, organic or inorganic substances; for drying the same, and recovering the solvent employed. March 30

3832 A. G. Wass. An improved lubricant. April 16

3833 A. G. Wass. An improved lubricant. April 16

XII.—PAINTS, VARNISHES, AND RESINS.

APPLICATIONS.

4267 A. Fromentin, London. Manufacturing a white colour called double carbonate, to be used as a painting colour. March 22

4278 W. Corbould, London. Improvements in the manufacture of whiting. March 22

4331 T. Kenyon, Manchester. Improvements in the preparation of pigments, and in the manufacture and treatment of bye-products therefrom. Complete specification. March 23

4607 R. M. Collingham, Manchester. Improvements in apparatus or presses used in the manufacture of black lead or other material for forming it into blocks. March 28

5545 S. Snell and A. W. Sanderson, Birmingham. A new or improved apparatus for the heating, melting, softening and burning of cements, paints, and the like for various purposes. April 16

5586 F. Crane—From J. Hale, United States. Improvements relating to the preparation of lacquers and varnishes, and to the method of applying the same for coating metallic or other articles. April 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

7497 J. Cameron. Antifouling composition for ships. March 23

1887.

3791 T. Garton. Transparent protective enamel or varnish. April 16

XIII.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

4384 H. Jamelle, London. An improved process for tanning hides and skins. March 23

5521 G. Delfos, London. See Class XX.

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

6138 R. Baker and W. Baker. Manufacturing leather from seal splits. April 16

7747 E. P. Nesbit. An improvement in tanning. April 9

XIV.—AGRICULTURE, MANURES, ETC.

APPLICATIONS.

4854 N. Proctor, Alfreton. An apparatus for creating vapours from a chemical compound for the destruction of insects. April 1

5532 E. Edwards—From J. Jeger. See Class XVII—C.

XV.—SUGAR, GUMS, STARCHES, ETC.

APPLICATIONS.

4397 H. W. Walker and T. L. Patterson, Glasgow. Improvements in apparatus for moulding and refining sugar. March 24

4407 A. Trebitsch, London. Apparatus and process for rendering amber waste available for manufacture. March 24

5066 A. Seyberlich and A. Trampedach, London. Improvements in and relating to the manufacture of grape sugar. April 5

5459 A. Schuhmann, London. An improved manufacture of a non-fermentable cementitious body soluble in water, from starch. April 14

5460 A. Schuhmann. An improved manufacture of dextrine or soluble starch free from smell and taste. April 14

5579 W. H. Hope, London. Increasing the durability and hardness of gutta-percha. April 16

COMPLETE SPECIFICATION ACCEPTED.

1886.

7970 M. Blake and J. Barclay. Improvements in and connected with sugar mills. April 16

XVI.—BREWING, WINES AND SPIRITS.

APPLICATIONS.

4332 J. France, Halifax. A new treatment of excisable liquors. March 23

4138 O. Imray, London—From F. W. Wiesebrock, United States. A process and apparatus for drying and cooling malt, grain, and other substances. Complete specification. Mar. 21

4530 J. W. Bailey and J. A. R. Greaves, London. The Manufacture of a new or improved saccharum for the use of brewers, distillers and vinegar makers. March 26

4863 F. Faulkner and W. Adlam, London. Improvements in and apparatus for effecting the process of sterilising "yeast-press drawings," "returns," and other waste liquids in brewing, vinegar-making, and other like processes. April 1

5337 I. A. F. Bang and M. C. A. Ruffin, London. A process and apparatus for purifying crude spirit and regenerating the purifying agent. April 12

5378 F. J. von der Ropp, London. Improvements in or relating to the treatment of yeast. April 13

COMPLETE SPECIFICATION ACCEPTED.

1886.

8082 W. S. Squire. Manufacture of yeast April 20

XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, ETC.

APPLICATIONS.

A.—CHEMISTRY OF FOODS.

17046 A. J. P. Larieux and H. Gregoire, London. An improved food for horses and other animals. December 29, 1886. Previously included in No. 17046 of 1886.

4203 T. Kerfoot, Manchester. Preparing a dry saccharated extract of tea from which a cup of tea can be quickly made by the addition of boiling water. March 21

4271 A. Walker, London. Improvements in the manufacture of yeast. March 22

4836 P. E. Establie, London. Improvements relating to barrels or receptacles for the preservation and transport of meat, fish, and other substances. March 31

5267 W. H. Gilruth, London. Improved means and apparatus for treating tea leaves and other vegetable matter to evaporate moisture therefrom. April 9

5362 J. B. Fabre and L. Bergel, London. An improved dry colouring powder for cheese, butter, and other products. April 12

5535 A. P. Wire, London. A new compound applicable especially for the preservation of animal and vegetable substances. April 15

C.—DISINFECTANTS.

4283 A. Dupré and C. N. Hake, Westminster. Improvements in the preparation of disinfectants, deodorants, and antiseptics. March 22

4355 E. R. Blumstone, London. Improvements in disinfectants. March 23

5393 H. Hermite. See Class VII

5532 E. Edwards, London—From J. Jeger, Poland. A new or improved material to be used as a disinfectant, manure, preservative against decay, and for other purposes. April 15

COMPLETE SPECIFICATIONS ACCEPTED.

A.—CHEMISTRY OF FOODS.

1886.

7644 H. H. Lake—From N. Muller. The preservation of alimentary substances. April 9

7862 G. Grout. An improved preparation of cocoa and chocolate. April 16

17017 M. Samelson. Manufacture of liquid extract of coffee. March 30

B.—SANITARY CHEMISTRY.

1886.

4544 T. Reid. Apparatus and method for clarifying sewage, and filtering large volumes of water. March 26

4572 F. Petrie. Disinfection of sewage, waste liquors, and the like. March 30

4609 T. G. Hardie. Furnace for the combustion of town refuse, etc., and utilisation of the resultant products. March 30

6306 J. S. Edwards and J. Edwards. Apparatus for drying waste animal matter, etc. March 23

6813 J. G. Lorrain. Improvements in filtration. March 23

7333 J. Fenton. Purifying, precipitating, and filtering sewage, drainage, etc. March 30

1887.

2766 J. Y. Johnson—From La Société G. Boone et J. Nory Decantation apparatus for clarifying and purifying water and other liquids. April 16

2860 H. Davey. Method and means for automatically raising sewage. April 20

C.—DISINFECTANTS.

1886.

6819 W. Thompson. The employment of certain substances for antiseptic purposes. March 23

8509 A. Boake and F. G. A. Roberts. Improvements in disinfectants. April 9

XVIII.—ELECTRO-CHEMISTRY.

APPLICATIONS.

4114 L. R. Davies and M. Shearer, London. Improvement for protection of elements (while in solution) of batteries or cells. March 18

4126 M. Bernard and E. Bernard, London. An improved process for the electrolysis of certain double chlorides. March 18

4219 C. Desmazures, London. Certain improvements in accumulators of electricity or other primary or secondary galvanic batteries. Complete specification. March 21

4225 G. Hookham, London. Improvements in electricity meters, partly applicable to dynamo-electric generators and motors. March 21

4303 W. Main, Brooklyn, U.S.A. Improvements in and relating to secondary batteries. Complete specification. March 22

4311 H. H. Lake—From A. Vanwyck Meserole, U.S.A. Improvements in and relating to secondary batteries. Complete specification. March 22

4322 J. Hopkinson and E. Hopkinson, London. Dynamo-electric machines. March 22

4460 T. Parker, Manchester. Improvements in electro-dynamic and dynamo-electric machines. March 25

4472 S. P Thompson, London. Improvements in electro-deposition of cobalt. March 25

4527 L. Epstein, Liverpool. Improvements in electrodes applicable for use in primary or secondary batteries. Complete specification. March 26

4571 W. E. Heys—From J. Beattie, jun., United States. Improvements in the construction and manufacture of zincs for galvanic batteries. March 28

4577 H. C. Beland, London. Improvements in electric secondary or storage batteries. March 28

4618 C. L. Tweedale, Manchester. Improvements in primary batteries. March 29

4664 W. P. Thompson—From E. H. Cowles and A. H. Cowles, United States. Improvements in or relating to electric furnaces applicable for making aluminium, and for other purposes. Complete Specification. March 29

4667 W. P. Kookogey, London. Improvements in galvanic battery solutions. Complete specification. March 29

4744 H. J. Harris, London. Means for supporting or suspending elements in electric batteries. March 30

4781 The Electrical Power Storage Co. Limited and H. W. Butler, London. Improvements in electric batteries. March 30

4823 C. H. Cathcart, London. An improved galvanic battery. March 31

4824 O. C. D. Ross, London. Improvements in the method of and in apparatus for generating electro-magnetic currents. March 31

4832 H. Leipman, London. Manufacture and construction of carbon "plates" or electrodes for use in primary batteries and for electro-metallurgical, electrolytical, and otber electrical purposes. March 31

4931 M. Bailey and J. Warner, London. An improved construction of battery and method of regulating the same. Complete specification. April 2

5009 J. T. Armstrong, London. A new and improved method of charging, cleansing, changing, and varying the chemicals and liquids used in secondary batteries. April 4

5096 J. Kapp, London. Improvements in dynamo-electric Machinery. April 5

5125 G. E. Dorman, Stafford. Improvements in thermo-electric elements. April 6

5140 W. H. Quarterman, London. Improvements in galvanic batteries. April 6

5193 G. A. Grindle, London. Improvements relating to a system of generation and distribution of electricity. April 7

5303 H. W. Ravenshaw, W. T. Goolden, and A. P. Trotter, London. Improvements in dynamo-electric machines. April 12

5162 W. H. Scott and E. A. Paris, London. Improvements in dynamo-electric machines. April 11

5505 H. W. Ravenshaw, W. T. Goolden, and A. P. Trotter, London. Improvements in dynamo-electric machines. April 15

5562 W. Maxwell, London. A system of generating, re-producing, and distributing electricity. April 16

5583 H. Liepmann, London. Improvements in galvanic batteries. April 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

2880 H. H. Lake—From G. E. Cabanellas. Apparatus for the generation and utilisation of electrical energy. March 30

4662 F. King. Automatic electrical distribution and charge of secondary batteries. March 30

4751 H. S. Maxim. Application of magnetism or electro-magnetism for the separation of metals, and for other purposes; and apparatus therefor. April 2

5092 A. Rust. Thermo-electric generators. April 9

6422 J. G. Statter and S. L. Brunton. Armatures for magnets or dynamo-electric generators. March 23

7004 R. E. B. Crompton. Apparatus for generating electricity. April 2

7189 J. E. Pearce. Primary voltaic batteries. March 30

7353 P. R. de Faucheux d'Humy. Galvanic batteries. April 2

7596 J. Pitkin. Elements for secondary batteries. April 9

7704 E. J. Houghton. Fuse for dynamo-electric machinos. April 9

10186 C. W. Hill. Electric generators and motors. March 26

1887.

1337 N. W. Perry. Galvanic cells. April 9

2721 C. G. Curtis, F. B. Crocker, and S. S. Wheeler. Electric batteries. April 9

2835 G. Y. Lagarde. Improvements in electric batteries, and means for putting same into and out of action. March 26

XIX.—PAPER, PASTEBOARD, ETC.

APPLICATIONS.

4619 T. M'Dougall and F. Lindley, Glasgow. Improvements in the manufacture of paper, and in apparatus therefor. March 29

5269 G. Pitt—From R. P. Pictet and G. L. Brelaz, Switzerland. Improvements in the manufacture of paper from wood, and in apparatus therefor. Complete specification. April 9

5296 L. Bastet, London. The manufacture of waterproof and combined water- and fireproof paper. Complete specification. April 9

5406 W. Bertram, Glasgow. Improvements in drying paper. April 14

5425 W. Bertram, Glasgow. Improved mechanism for drying paper. April 14

5528 T. Goodall and T. Webster, London. Improved means for straining pulp. April 15

5649 C. Barataud, London. An improved machine or apparatus for reducing material for the manufacture of paper. Complete specification. April 18

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

7530 E. de Pass—From La Société de Lafarge, Lèbre et Cie. A process and apparatus for rendering all kinds of paper impermeable and transparent; the said apparatus being applicable for rendering cotton and other fabrics impermeable. March 26

17159 N. Browne—From J. Scherbel and T. Remus. Apparatus for drying strawboard, cardboard, and the like. April 16

1887.

3927 C. Russell and P. H. Craigin. Paper-pulp screens. April 16

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

5524 G. Delfos, London. An oily chemical preparation for the manufacture of Russian leather. April 15

5590 E. Merck, London. Improvements relating to the manufacture of naphthalol, and to the utilisation of the same for medicinal purposes. April 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

7903 W. L. Wise—From E. Mourlot, fils. Obtaining certain products or substances from essence of birch bark, and utilising the same in the manufacture or production of certain compounds or substances. April 16

XXI.—EXPLOSIVES, MATCHES, ETC.

APPLICATIONS.

4110 R. W. Punshon and H. J. Maclure, London. Improvements in the manufacture of explosive compounds. March 25

4111 H. J. Maclure, London. Smokeless gunpowder. March 25

4636 E. Hollanders, Portsea. An improved electric safety-pistol for firing canons and explosives. March 29

4713 C. D. Abel—From H. Schöneweg, Germany. Improvements in explosive compounds and safety cartridges for blasting purposes. March 29

5366 G. A. Farini, London. Improvements in ammunition for rifles, sporting and other guns, pistols or revolvers; also applicable to heavy ordnance. Complete specification. April 13

5161 W. J. Brewer, London. An improved land torpedo. April 11

5538 W. J. Brewer. Improvements in torpedoes. April 15

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

7911 J. Rigby. Improvements in ammunition. April 16

9166 C. Roth. Manufacture of explosives. April 9

1887.

2679 C. Roth. Manufacture of explosives. April 2

3173 S. H. Neuly and L. Hutchins. Marine torpedoes. April 9

Printed and Published by EMMOTT & Co., New Bridge Street, Strangeways, Manchester, for the Society of Chemical Industry.

OF THE
Society of Chemical Industry:
A MONTHLY RECORD
FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 5.—Vol. VI.

MAY 31, 1887.

Non-Members 30/- per annum; Members 21/- per Set; Single Copies 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.

COUNCIL FOR YEAR ENDING JULY, 1887.

President: ***David Howard.***

Vice-Presidents:

Sir I. Lowthian Bell, Bart., F.R.S.
Prof. James Dewar, F.R.S.
Dr. Peter Griess, F.R.S.
Dr. Ferdinand Hurter.
E. K. Muspratt.
Dr. W. H. Perkin, F.R.S.
Sir H. E. Roscoe, M.P., F.R.S.
John Spiller.
E. C. C. Stanford.
J. C. Stevenson, M.P.
John Williams.
Philip J. Worsley.

Ordinary Members of Council:

John Calderwood, F.R.S.E.
Eustace Carey.
R. Forbes Carpenter.
Henry Doulton.
Dr. John Evans, F.R.S.
S. H. Johnson.
Ivan Levinstein.
John Pattinson.
S. A. Sadler.
Sir Bernhard Samuelson, Bart., M.P.
Sir Chas. Tennant, Bart.
Lewis T. Wright.

With Sixteen Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Ludwig Mond, 20, Avenue Road, Regent's Park, N.W.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

NOTICES.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those members of Council whose names are placed in italics in the annexed list, will retire from their respective offices at the forthcoming Annual General Meeting.

Professor James Dewar, F.R.S., has been nominated to the office of President, and Mr. David Howard has been nominated Vice-President under Rule 11.

Professor Clowes, Mr. J. Neilson Cuthbertson, Mr. Ivan Levinstein, and Professor W. A. Tilden, F.R.S., have been nominated Vice-Presidents under Rule 8; and Mr. B. S. Proctor has been nominated Ordinary Member of Council under Rule 17, in the place of Mr. Levinstein, nominated Vice-President.

The Treasurer and Foreign Secretary have been nominated for re-election.

Members are hereby invited to nominate fit and proper persons to fill four vacancies among the Ordinary Members of Council under Rule 18. Special nomination forms for this purpose can be obtained from the General Secretary upon application.

Extract from Rule 18:—"No such nomination shall be valid, unless it be signed by at least ten members of the Society, who are not in arrear with their subscriptions, nor unless it be received by the General Secretary, at the Society's Office, at least one month before the date of the commencement of the Annual General Meeting, to the election to take place at which it refers. Nor shall any such nomination be valid if the person nominated be ineligible for election under Rules 12 or 15. No member shall sign more than one nomination form."

Notice is hereby given, that the next Annual General Meeting will be held in Manchester on Wednesday, Thursday, and Friday, the 13th, 14th, and 15th of July next. Detailed arrangements and the programme of proceedings will appear as soon as complete.

Comment having been made on the delay in reprinting the numbers for January, 1882 and 1883, the Secretary begs to inform those whom it may concern, that the delay is due to the fact that up to the present not more than twenty orders for those numbers have been received. It is hoped that this notification may stimulate those who desire to complete their sets, to make early application with a view to expedite the consideration of the question of reprinting by the Council. Notice is also hereby given that the numbers for January and February, 1886, being exhausted, no orders for those copies, nor for complete sets of Vol. V., can be executed.

Authors of communications read before the Society or any of its Local Sections are requested to take notice that, under Bye-Law 43, they cannot receive the prescribed 50 copies of their communications unless they comply with the condition laid down in that Bye-Law—viz., that they give notice of their desire to receive such copies upon their manuscript before sending it to the Editor. Mention should also be made as to whether the Discussion is to be included in the reprint.

CHANGES OF ADDRESS.

Herbert W. Bainbridge: Journals, etc., to Malvern Hall, Solihull, near Birmingham.

G. H. Beckett, l/o Forest Gate; 21, Howard Street, Horton Lane, Bradford, Yorks.

J. C. Belcher, l/o Brighton; c/o Sanitas Co., Limited, Letchford's Buildings, Three Colts Lane, Bethnal Green, E.

Jas. Beveridge, l/o Cardiff; Main Street, Frodsham, Cheshire.

C. W. Bickerton, l/o Bosden; Torkington Fold, Norbury, near Stockport.

Dr. L. Claisen, l/o Coln; Marsstrasse 1 *a* 2, Munchen, Bavaria.

W. P. Cochrane, l/o Redcar; Holmhurst, The Park, Middlesbro'-on-Tees.

Wm. Donald, l/o Pembrey; 29, Eglinton Street, Saltcoats, N.B.

H. Fergusson, l/o Manchester; Prince Regent's Wharf, Victoria Docks, E.

And. Ferrie, l/o Corporation Street; Harpurhey Chemical Works, Manchester.

H. Forth, l/o New Basford; Beech Avenue, Sherwood Rise, Nottingham.

C. J. Fox, l/o Aldersgate Street; 17, Charterhouse Buildings, London, E.C.

Wm. Glover, l/o Silvertown; 180, Hulme Hall Lane, Miles Platting, Manchester.

R. Grimwood, l/o Upper Holloway; 41, Lady Margaret Road, London, N.W.

J. Hammond, l/o Lewes; Resident Engineer, Gas Works, Eastbourne.

W. Hoghen, l/o Edinburgh; c/o Monville Phibrolithoïd Co., Limited, Monville, Seine Inférieure, France.

Dr. H. Kupferberg, l/o Blackley; 49, Cleveland Road, Higher Crumpsall, Manchester.

F. H. Leeds, l/o Forest Gate; 29, Bouverie Road, Stoke Newington, N.

Otto Luthy, l/o Church Street; 2336, Fairmount Avenue, Philadelphia, Pa., U.S.A.

T. R. Marshall, l/o Edinburgh; bei Herrn Kolle, 9/3 Dachauer Strasse, Munchen, Bavaria.

Jno. Murphy, l/o Prince's Park; Kingston House, Aigburth Road, Liverpool.

F. Nettlefold, l/o 52; 21, Sterndall Road, West Kensington, W.

Chas. Renard, l/o L'Estaque; 25, Allées de Meilhan, Marseilles, France.

T. Rowley, l/o Manchester; Croston Cottage, Alderley Edge, Cheshire.

Wallace Thorneycroft, l/o Glasgow; Tettenhall Towers, Wolverhampton.

H. Wager, l/o Lymington; Larich Bhan, Loch Awe Side, Dalmally, Argyllshire, N.B.

A. J. Watts, l/o Pernambuco; 40, Goldhurst Terrace, South Hampstead, N.W.

G. S. V. Wills, l/o Southwark; Arundel Lodge, Tulse Hill, S.W.

L. Wykes, l/o Oldbury; Minas de Rio Tinto, Huelva, Spain.

CHANGES OF ADDRESS REQUIRED.

C. S. Doggett, l/o 53, Karl Strasse, München.

Jas. Towns, l/o Morgan Street, Canning Town, E.

LIST OF MEMBERS ELECTED, MAY 23, 1887.

F. W. Babington, School of Practical Science, Toronto, Canada, demonstrator of applied chemistry.

F. J. Beaumont, 42, Trinity Square, Borough, S.E., lecturer on science.

J. Edwin Boon, High Street, Brading, Isle of Wight, chemist.

J. M. Collett, 7, Brunswick Square, Gloucester, chemical manufacturer.

Jno. Craig, Clippens Villa, by Johnstone, N.B., manager of oilworks.

Thos. Goodall, Hendon Grange, Sunderland, paper manufacturer.

Hugh Hastings, 13, Neal Street, Bradford, Yorks., student of chemistry.

Alf. H. Knight, 18, Chapel Street, Liverpool, metallurgical chemist and assayer.

G. A. Koenig, University of Pennsylvania, Philadelphia, U.S.A., professor of mineralogy and metallurgy.

Eardley B. Manby, Lightbounds, Halliwell, Bolton-le-Moors, manager of bleach and dyeworks.

Edmund Milnes, Seedfield, Bury, Lancashire, manufacturer of extracts for dyeing and printing.

Philip H. Rathbone, The Cottage, Green Bank, Liverpool, Chairman of Weldon's Chlorine Co.

Thos. B. Saunders, 8, Melbourne Place, Horton Lane, Bradford, Yorks., manufacturing chemist.

Willis Scrutton, University College, Gower Street, W.C., demonstrator.

H. Thornton, 5, George Street, Euston Road, London, N.W., chemist.

Jno. Turney, Trent Bridge Leather Works, Nottingham, tanner.

Jos. T. Wood, Trent Bridge Leather Works, Nottingham, tanner.

London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: David Howard.

Committee:

Sir F. A. Abel.
H. E. Armstrong.
W. Lant Carpenter.
W. Crowder.
C. Graham.
S. Hall.
A. K. Huntington.
R. Messel.
B. E. R. Newlands.
B. Redwood.
T. Royle.
John Spiller.
G. C. Trewby.
J. Williams.

Hon. Local Sec. and Treasurer: Thos. Tyrer, Garden Wharf, Church Road, Battersea, S.W.

The meetings of the London Section will be held on the first Monday in each month.

SESSION 1886—87.

Prospective Arrangements.

June 6.—Dr. H. E. Armstrong, "The Alkaloids—the Present State of Knowledge concerning them, and the Method employed in their Investigation."

" Mr. Boverton Redwood, "Notes of a Recent Visit to some of the Petroleum-producing Territories of the United States and Canada."

Mr. J. Ruttle, F.I.C., F.C.S., "Further Notes on the Analysis of Certain Fertilisers."

July 13, 14 and 15.—Annual Meeting in Manchester.

Notices of Meetings and Papers will be found in the Scientific Journals.

Notices of papers and communications to be made to the Local Secretary.

Meeting held May 2, 1887.

RECENT BACTERIOLOGICAL RESEARCH IN CONNECTION WITH WATER SUPPLY.

BY PERCY F. FRANKLAND, PH.D., B.SC. (LOND.), F.I.C.

Eighteen months ago I had the honour of introducing to the notice of this Society some of those novel methods of bacteriological research which have given such an impetus to this study during the past few years, and by means of which such important results have been obtained.

The functions of micro-organisms are so closely connected with such numerous industrial processes, and are of such wide practical significance, that I cannot but think that the Journal of this Society is a medium pre-eminently fitted for bringing to the knowledge of practical men the progress which is being made in a subject with which so many are consciously, or unconsciously, directly or indirectly concerned.

In my previous communication I endeavoured to point out how these new methods of investigation could be rendered available for the solution of a number of problems which have long presented themselves to those interested in the subject of water-supply, but which had previously been unapproachable owing to the technical difficulties with which they were surrounded. I pointed out more especially how the efficiency of filtration and other methods of water-purification could now be determined from an entirely new point of view, and one which for many purposes was of much greater importance than the chemical standard which had hitherto been alone available. At the present time I think no one will dispute that the biological standard of purity, as regards drinking-water, is of more importance than the chemical standard, for it has long been admitted that the *greater* dangers of contaminated drinking-water reside in the presence of living organisms and not of unorganised organic matter. I say the "*greater*" dangers of contaminated water, for there can be no doubt that minor disturbances may be caused by the presence of excessive quantities of organic matter in water, irrespectively of the presence of pathogenic organisms; but cases of such gross pollution in which toxic effects result from the presence of large quantities of organic matter are comparatively rare, are almost exclusively confined to private supplies from wells, tanks and cisterns, and possess but little interest in connection with the supply of water on the large scale.

The new bacteriological methods, as I have already pointed out, admit of being applied to the examination of water supplies in such a manner as to ascertain what is the efficiency of the purifying processes—natural or artificial—upon which the safety of the supply is supposed to depend. In my previous communication I dwelt at some length on the results which are obtained when water is submitted to filtration on the small scale in the laboratory, and I pointed out how substances which had hitherto been regarded as of practically no value for filtration, could, when employed in a sufficiently fine state of division, be made to act as highly efficient filters, at any rate for a short period of time.

I propose, in the first instance, this evening to bring before you the results which I have obtained during the past year in my monthly examinations for the Local Government Board of the London Water Supply, by the methods in question.

These results are of interest, not only as illustrating the variations in the amount of organic life present in the different waters throughout the year, but also in showing the effect of the processes practised in the purification of water on the large scale; for besides determining the number of developable microbes in each of the various waters, the number is likewise determined in the unfiltered river-waters at the points where the latter are abstracted for supply.

In Table I. I have recorded the total number of micro-organisms found in one cubic centimetre of each of the waters.

In connection with this table there is one point to which I particulrly desire to draw attention, and that is, that in the case of the river-waters the samples richest in micro-organisms are those collected in the winter months, and not in the summer. It might have been anticipated that the reverse of this would be the case, and that the higher temperature being favourable to the growth and multiplication of the organisms, the latter should be more prevalent in the summer than in winter. It must, however, be remembered that in summer the rivers are principally fed by spring-water, and receive comparatively little surface-drainage, whilst in winter the rivers are generally more or less in flood, and are swollen by large volumes of surface-water, which is naturally rich in micro-organisms. The fact that the filtered waters also contain, as a general rule, the smallest number of organisms in the summer and not in the winter, clearly shows that the figures obtained do really give a picture of the work done in the purification of the water, and are not materially affected by any process of multiplication which may be favoured by a high temperature.

It will, moreover, be seen that in every case a very much smaller number of micro-organisms was found in the filtered than in the unfiltered waters, and in most cases this difference is exceedingly striking indeed.

In Table II. this difference between the filtered and unfiltered waters is expressed as a percentage

number, exhibiting in each case how many out of every 100 microbes present in the original water have been removed in the processes of treatment adopted by the companies.

It is particularly interesting to find from this table that the results obtained by the various companies are by no means identical, but that some companies are almost uniformly more successful than others. In another place (the Institution of Civil Engineers) I have pointed out that these differences correspond in a remarkable manner with certain differences in the mode of treatment, such as the time of storage, rate of filtration, thickness of filtering materials, etc., adopted by the various companies. This is a point deserving the special attention of water engineers, and it is especially desirable that the connection between the mode of treatment and the results obtained should be elaborated by a systematic series of experiments made on the individual filter-beds, instead of upon the whole supply.

Quite recently I have had an opportunity of applying these tests to the water supply of a large town in the North of England, and the results are of interest, by way of comparison with those obtained in the case of the Metropolitan supply, as the circumstances are in many respects similar.

The water supply in question is derived from a river which receives the drainage of several towns of considerable size above the point where the water is abstracted.

The following four samples of water were collected as representative of the conditions of supply, and these four samples were respectively submitted to chemical and bacteriological examination.

Sample 1.—Collected from the river about 27 miles above the intake, and down to this point the river has received no drainage from any place of considerable size.

Sample 2.—Taken about 16 miles above the intake in question, and 10 miles below a town of 7000 inhabitants, from which, and from a smaller town, it receives sewage.

Sample 3.—Taken from the river at the intake, between which, and the point at which Sample 2 was taken, there is no noticeable source of pollution.

Sample 4.—The water as supplied to the town in question, and after undergoing the processes of storage and filtration.

	Remarks	Slightly turbid.	Slightly turbid.	Slightly turbid.	Very slightly turbid.
	Number of colonies obtained on cultivation of 1cc. of water	1,800	33,400	31,200	122

From the above it will be seen that, whilst the river at the points 1, 2, and 3 is of much the same chemical composition in each case, the condition as regards the amount of microbial life present in the water at the point No. 1 is very different from that at the points Nos. 2 and 3. Now it must be observed that the increase in the number of micro-organisms which No. 2 exhibits, as compared with No. 1, is coincident with the admission into the river between these two points of the sewage of the two towns referred to above, whilst the practical equality in the numbers found at points 2 and 3 corresponds with

---

* The samples in question were collected in the forenoon, with all due precautions, and were received at my house and there submitted to plate-cultivation on the evening of the same day, so that there was no time for any disturbance of the results through multiplication in the interval between the times of collection and cultivation.

the 16 miles' length of river in which, as we have seen, there is no noticeable source of pollution.

Most striking of all, however, is the enormous reduction in the number of microbes found in the case of the Sample No. 4, which is the water actually supplied, and which, as regards chemical composition, is almost an exact duplicate of No. 3, the differences exhibited by the two samples being almost within the limits of experimental error.

The reduction in the number of microbes before distribution to the town in question thus amounts to no less than 99·6 per cent., which compares favourably with the results similarly obtained in London, for the average reduction in the case of the Thames water during the whole year 1886 amounted to 98·0 per cent.

In connection with the results to which I have just referred, I wish it to be most clearly understood that no conclusions whatever, as to the relative excellence of the various waters, are to be drawn from their greater or less freedom from micro-organisms, any more than it is possible, on the strength of chemical composition, to say that one water is more wholesome than another. On the other hand, these determinations undoubtedly do indicate what would be the probable fate of any harmful organisms gaining access to the sources of supply, and what is the relative chance of their reaching the consumers; *for that method of treatment which abolishes the largest proportion of organisms of all kinds is also the most likely to abolish any pathogenic forms should they be present.*

Experiments on the Filtration of Water on the Small Scale.

Since the communication of my previous paper, further experiments have been made on the subject of domestic filtration, but whilst my experiments were made with a view of testing the efficiency of various materials when employed in the most advantageous manner, these later experiments, on the other hand, have been made with filters which are actually in the market at the present time.

Were I to follow my own inclinations in the matter, I should pass over these experiments without any comment, as it is certainly my experience that any public reference, whether favourable or unfavourable, to proprietary articles of any kind is invariably followed by annoyance and unpleasantness. I feel, however, that I should be but imperfectly executing the task which I have undertaken of bringing before you the recent progress in this subject, without briefly recapitulating the results which have been obtained in these investigations.

The experiments in question have been obtained by Dr. Plagge, of the Hygienic Institute of Berlin, who published his results last autumn before the Public Health Section of the German Association of Naturalists and Physicians.

Dr. Plagge has examined a great variety of filters—viz.: (1.) *Carbon filters.* (2.) *Stone and sand filters.* (3.) *The spongy iron filter.* (4.) *Paper filters* of several kinds. (5.) *The porous earthenware filters* of Chamberland (Paris), Olschewsky (Berlin), and Hesse (Schwartzenburg). (6.) *The Asbestos filters* of Breyer (Vienna), Hesse, Arnold & Schirmer (Berlin).

In experimenting with these various forms of filter, Dr. Plagge found—

(1.) That the *carbon filters* not only admitted of the free transmission of micro-organisms, but that in some cases the number of microbes in the filtrate greatly exceeded that in the unfiltered water; thus in one case the

Unfiltered water yielded 68 colonies per cubic centimetre.

whilst—

The filtered „ „ 12,000 „ „ „

It may be remembered that a similar case was cited by me in my previous communication, in which an experimental filter of animal charcoal, which I had had in operation for one month, gave the following results:—

Unfiltered water yielded ......2800 colonies per cc.
Filtered „ „ ..... 7000 „ „

In these cases the filtering medium obviously acts as a hotbed for the development of micro organisms.

(2.) The *stone and sand filters* were all found to be worthless.

(3.) The *spongy iron filter* yielded the following results:—

Unfiltered water yielded 38,000 colonies per cc.
Filtered „ „ 18,000—24,000 „ „

(4.) The *paper filters* yielded very unsatisfactory results; thus in one case in which filtration was carried under a pressure of 1¾ atmosphere—

Unfiltered water yielded ....40,000 colonies per cc.
Filtered „ „ .... 8,000 „ „

And in another case at a low pressure (½ atmosphere), the 40,000 colonies in the unfiltered were reduced to 4000 in the filtered water.

(5.) The *earthenware filters*, on Pasteur's principle, gave in nearly every instance a filtrate practically free from micro-organisms. Thus in one case the unfiltered water yielded 284, and the filtered only 4 colonies per cubic centimetre.

This result is similar to that previously obtained by me in the filtration of London water through a Chamberland filter.*

(6.) The *asbestos filters* gave results essentially similar to those obtained with the earthenware filters.

These results of Dr. Plagge's speak for themselves, and require no further comment; they obviously enable us to classify these domestic filters in three definite groups:—

(1.) Filters which are highly efficient.
(2.) Filters which are inefficient.
(3.) Filters which are not only inefficient, but absolutely injurious to the purity of the water.

Experiments with Specific Organisms.

In all experiments with natural waters we have, as I have already pointed out, to deal principally with organisms which in themselves are not known to be endowed with dangerous properties, and consequently as the results possess only an indirect significance, it has been thought desirable to conduct experiments in which definite organisms, some of which are known to possess pathogenic properties, are employed.

The object of these experiments has been to ascertain what is the fate of these various pathogenic organisms when they are artificially introduced into different kinds of natural water, and in order to simplify the investigation—I might almost say, in order to bring the investigation within the limits of experimental possibility—the natural waters into which the pathogenic forms are introduced are previously freed from all other microbes by sterilisation. The method of investigation, which has been followed in the more systematic of these experiments, has been to introduce a very minute quantity of a pure cultivation of the particular organism in question into a large quantity of water previously sterilised, and contained in a sterile vessel protected from aërial contamination. The inoculated water is then rendered homogeneous by agitation, and a measured portion removed with a sterilised pipette, and submitted to plate-cultivation in the ordinary way. Thus the initial number of organisms of the particular kind in a given volume of water is ascer-

---

* "The Removal of Micro-organisms from Water," Proceedings Royal Society, 1885.

tained. The infected water is then allowed to stand for a definite length of time—so many hours, days, weeks, months, etc.—and then again submitted to plate cultivation at suitable intervals, the sample being of course thoroughly agitated immediately before removing a portion with the sterilised pipette for cultivation.

I have myself carried out a large number of experiments in this manner on some of the best characterised organisms—viz.:—

1.—Koch's "comma" spirillum of Asiatic cholera.

2.—Finkler-Prior's "comma" spirillum, which is an organism very closely resembling Koch's comma, and formerly erroneously supposed to be identical with it. It was originally found in a case of European cholera.

3.—The bacillus pyocyaneus, an organism which gives rise to the greenish-blue colouring matter frequently present in abscesses.

4.—The micrococcus of erysipelas, the undoubted cause of this well-known disease.

5.—The bacillus anthracis, the unquestionable cause of splenic fever in cattle and of woolsorters' disease or malignant pustule in man.

The behaviour of these several organisms was studied when they were introduced respectively into distilled water, deep-well water, filtered Thames water, and sewage.

VITALITY OF KOCH'S COMMA SPIRILLUM IN SEWAGE, AND IN FILTERED THAMES WATER.

	(Incub.)	—	188	0	0	0	—	—	—	—

* These figures indicate the number of undoubted comma colonies; there was in each of these two cases also an immense number of other colonies due to a micrococcus.

Thus the "comma" spirilla were found in every case to flourish and multiply abundantly in sewage, whilst in deep-well and in filtered Thames water, although they were still demonstrable on the ninth day, they were present only in small number. It is moreover worthy of notice that both in the case of the deep-well and filtered Thames waters the numbers were greatly reduced immediately after inoculation, whilst subsequently they distinctly increased, only again to diminish after the fifth or sixth day. This process of acclimatisation, which I have also observed in the case of the bacillus pyocyaneus, has been likewise noticed by Wolfhugel.

Indeed, in sewage, the comma spirilla are so permanent that, after 11 months, I have still found them abundantly present in the case of two experiments which I have carried on up to the present time. As only the earlier observations made in these experiments have been previously recorded,* I have collected the results in the above table.

In other cases in which a weak cultivation of the comma spirillum was employed, a much more rapid destruction of the organism was observed, the latter being no longer demonstrable after the first day.

The results obtained with Finkler's spirillum differed very strikingly from those observed in the case of Koch's comma. This is particularly interesting, in consequence of the many points of similarity, both in microscopical appearance and in their behaviour, in cultivations which these organisms present. The invariable result obtained with Finkler's spirillum was that the organism could no longer be demonstrated in any of the waters, not even in London sewage, after the first day. The vitality of Finkler's spirillum in water is, therefore, very much less than that of Koch's comma.

The bacillus pyocyaneus, on the other hand, exhibits a vitality in water which far exceeds that of the comma spirillum: for this organism, when similarly introduced, was found to multiply, not only in sewage, in filtered Thames, in deep-well, but even in distilled water, and only in very exceptional cases was any destruction of the bacillus observed. As already pointed out, however, there were several instances in which a rapid diminution in the number of introduced organisms was subsequently followed by an even still more marked multiplication than in the case of the comma spirillum.

Note.—It should be observed that when it is stated that an organism has multiplied in distilled water, it must be understood that this multiplication has doubtless taken place at the expense of those *traces* of organic matter which must of necessity be present in experiments of this kind.

More recently I have made somewhat similar experiments with the bacillus anthracis and with the micrococcus of erysipelas; two organisms which are most indisputably the causes of the two well characterised diseases with which they are associated.

An introductory word or two is necessary in connection with the experiments made with the bacillus anthracis. The bacillus anthracis is the micro-organism of all others of which perhaps the life-history has been most completely and satisfactorily worked out. Now the life-history of this organism is divisible into two parts—(1) the *bacillar* stage, and (2) the *spore*, or oviform stage. It has long been known that the vitality of micro-organisms is very different according as they exist in one of these stages or the other; in point of fact, that the spore is enormously more refractory than the bacillus. Thus the spores of anthrax can be exposed without injury to all manner of conditions of temperature, of desicca-

* "On the Multiplication of Micro-organisms." Proceedings Royal Society. 1886.

tion, of antiseptic action and the like which would be rapidly fatal to the bacilli of anthrax. Under ordinary circumstances, when anthrax grows in any cultivating medium, it is present in both the bacillar and in the spore form, and it is only when the organism is taken immediately from the blood or tissues of an animal dead of anthrax that the bacillus is with certainty obtained free from spores. It is, therefore, the practice, in making experiments in which it is desired to employ an absolutely sporeless growth of anthrax, to take portions of the blood or tissues of an animal freshly dead of this disease.

Bearing these facts in mind, therefore, it is obvious that in conducting any experiments on the vitality of this microbe in water it is altogether essential that we should employ the organism in its spore-form if any conclusions are to be drawn as to the power of water to act as a carrier of this disease.

The experiments which I have made in this direction have, therefore, been conducted with cultivations of anthrax in which spores were abundantly present. From such a cultivation (agar-agar) a small quantity, about the size of a drop, was taken on a sterilised platinum needle and introduced into 50cc. of sterilised distilled water contained in a small sterilised stoppered bottle. The bottle and its contents were then thoroughly agitated, and from it two cubic centimetres were taken out in a sterilised pipette and introduced into 1500cc. of sterilised London sewage, Grand Junction water, and distilled water respectively. The inoculated waters were thoroughly agitated and then three small sterilised flasks were partially filled with each, so that there were nine smaller samples, three of which contained infected sewage, three infected Grand Junction water, and three infected distilled water. Each of these flasks was of course immediately plugged with sterile cotton wool.

Now assuming that 1cc. = 20 drops, it will be seen that in preparing the first attenuation in the stoppered bottle the original cultivation was diluted $50 \times 20 = 1000$ times, and in inoculating this attenuation into the waters themselves a further dilution of $\frac{1500}{2} = 750$ took place, so that the total dilution effected amounted to no less than $1000 \times 750 = 750{,}000$. In other words, the infected waters contained only one part of the original cultivation in 750,000 parts of water. From these smaller flasks, at the intervals of time given below, gelatine plates were then prepared in the ordinary way, with all the customary precautions.

The results of these experiments are recorded in the table on next column.

Thus in the distilled water, in all three experiments, the number of developable anthrax organisms remained practically the same during the period of 61 days over which the observations were extended. There can be no doubt, therefore, that the spores of anthrax are wholly unaffected by this long residence even in distilled water. They obviously undergo no development—no numerical multiplication in this medium; but their vitality is unchanged, and they have only to be introduced into the ordinary cultivating media in order to display their usual activity and exhibit their characteristic appearances of growth.

In the Grand Junction water, of which the chemical composition is given below,* the phenomena were somewhat different, as in the course of the first five days after inoculation a perceptible diminution in the number of developable anthrax organisms took place, after which the number remained practically stationary as in the case of the distilled water. The explanation of this is not difficult to find. In the case

† On this day plates were prepared from the *first* attenuation of the erysipelas micrococcus, but were found quite sterile.

of the distilled water, doubtless all the organisms which cultivation, within even the first hour, revealed were spores, the anthrax bacilli perishing, as we know, so rapidly in this medium; whilst in the case of the Grand Junction water the anthrax bacilli required several days before their vitality was wholly extinguished, and it is not until the fifth day that the numbers recorded are due wholly to the residual spores which, as in the case of the distilled water, remain practically unaffected for the remainder of the time over which the observations were continued.

The experiments with the sewage again present further differences: the diminution in the course of the first few days is less marked than in the Grand Junction water, but subsequently a very decided multiplication takes place, clearly showing that in this medium the anthrax organism is not only able to preserve its vitality in the spore form, but that it is also capable of finding in it the means whereby to exercise the functions of nutrition and reproduction.

It is thus obvious that ordinary drinking water, even should it be practically as pure as distilled water, is capable of acting as the carrier of the virus of anthrax, and that sewage may not only act as the carrier, but forms a suitable medium for the growth and multiplication of this pathogenic microbe.

I should remark that these results are in precise accord with those obtained by Meade Bolton in the Hygienic Institute of Göttingen, who, in similarly conducted experiments, found that whilst the bacilli of anthrax became extinct between the third and sixth days, their spores remained unaffected for practically an indefinite time (many weeks) even in distilled water.

I will now turn to the last pathogenic organism with which I have experimented—viz., the *micrococcus of erysipelas*. The distilled water, Grand Junction water, and sewage employed in these experiments were the same as those used in the anthrax experiments, and the method of inoculation was essentially the same as that already described, excepting that the degree of dilution was not quite as great. The erysipelas organism was taken from a broth cultivation, the final dilution amounting to 75,000 times. As in the case of the anthrax experiments, the waters were preserved at about 20° C., or rather under. The results obtained are recorded above.

The results of these experiments, which were carried on simultaneously with those with anthrax, present a very striking contrast to the latter. Thus, even within one hour of infection, the micrococci of erysipelas could not be demonstrated in the distilled water, whilst in the sewage they were still demonstrable on the second day, and in the Grand Junction water, in two out of the three flasks on the fifth day, but not afterwards. In fact, so slight is the vitality of this organism in these dilute media that on the 21st day it was no longer demonstrable even in the first attenuation, in which the original broth culture was diluted about 100 times with distilled water.

It is of interest to compare with this behaviour of the erysipelas micrococcus the behaviour under similar circumstances of the other pathogenic micrococci which have been submitted to investigation in this respect. Meade Bolton has made similar experiments with the *staphylococcus pyogenes aureus*, and with the *micrococcus tetragenus*. The former of these is the commonest generator of suppuration, having been found in about 71 per cent. of all the abscesses which have been submitted to careful bacteriological examination. The M. tetragenus, on the other hand, is an organism found in the caverns of phtisical patients; it is not known to be pathogenic to man, but is highly pathogenic to mice. Now experiments with the staphylococcus pyogenes have shown that this organism was no longer demonstrable in distilled and in ordinary drinking water after the 20th to 30th day, whilst the micrococcus tetragenus when placed in similar water could not be detected on the 2nd to 4th day.

I have lastly to refer briefly to those experiments which have been made with the organism which is with very considerable probability regarded as the cause of typhoid fever. This organism, like anthrax, is known in two distinct forms, the bacillus and the spore. Owing to the different powers of resistance possessed by these forms, we find the typhoid organism exhibiting a very similar behaviour in water to that which we have already noticed in the case of anthrax. Thus we find the typhoid bacilli are less persistent in water than the spores, although even the bacilli were not destroyed by remaining 10 to 14 days in distilled water, and the spores, of course, are quite unaffected by an immersion of even much longer duration.

There is yet another point upon which a few words must be said, and that is as regards the influence which is exerted upon these pathogenic organisms by the non-pathogenic forms commonly present in water. Very little has yet been done in this direction, and in point of fact the enquiry is attended with considerable technical difficulties. There is, however, a very prevalent impression that the permanence of these pathogenic forms is much reduced by the simultaneous presence of non-pathogenic or saprophytic forms, which flourish in water. The evidence of this crowding out by the saprophytic forms is, however, far from convincing, and there are many facts which can be adduced and which tend to show that this destruction of pathogenic forms by saprophytic ones has been much exaggerated. Thus, in several of my experiments, the pathogenic organisms have been persistent in the presence of saprophytic forms which have accidentally gained access during the numerous exposures of the flasks in taking out portions for cultivation. Thus, the comma spirilla, which had retained their vitality for 11 months, were present, in company with countless numbers of a micrococcus which had accidentally gained access. Similarly in the anthrax experiments in two or three cases saprophytic forms were present at the same time.

There can be no doubt that in many cases it has been erroneously supposed that the pathogenic forms have been suppressed by the saprophytic, in consequence of the great difficulty attending the recognition of comparatively few of the former in the presence of large numbers of the non-pathogenic. Again, in many cases, no doubt, the experiments have been interrupted too soon, and an erroneous conclusion has been arrived at in consequence, which would have been avoided if the competition between the various forms had been permitted to continue longer. Thus it was formerly supposed that the comma spirilla possessed but little power of competing with the ordinary putrefaction bacteria, and that if a cultivation of comma spirilla became contaminated with putrefaction bacteria the latter soon altogether suppressed the comma spirilla. Quite recently, however, it has been shown by Gruber* that, although the putrefaction bacteria gain an enormous numerical ascendancy over the comma spirilla for some time, yet the vitality of the latter is by no means extinguished, and that if the struggle between the two is sufficiently protracted, until the process of putrefaction is less active, the presence of the comma spirilla can be again readily demonstrated by cultivation.

---

* *Gruber*, Wiener medicinische Wochenschrift, 1887, No. 7 & 8.

It is necessary, therefore, to exercise considerable caution in judging upon this point in the present state of our knowledge, and it would be highly premature to place too much reliance upon this alleged destruction of pathogenic forms by non-pathogenic ones.

The various investigations which we have considered this evening have many very obvious bearings on the practical aspects of water supply and general sanitation.

In the first place we learn, as I have before pointed out, that the ordinary process of treatment by storage, sand filtration, etc., produces a far more marked effect on the biological than on the chemical properties of the water. Moreover, that the differences in the mode of treatment as practised for the various branches of the Metropolitan river supply result in the attainment of different degrees of efficiency in the removal of micro-organisms, which render it highly desirable that the individual details of these processes should be systematically investigated, with a view to bringing the several factors of treatment to the highest state of practical perfection.

As regards filtration on the small scale, we learn that most of the filters at present in use are, from a biological point of view, highly inefficient, or even worse than inefficient, and that it is extremely important that the private householder should be made fully aware of what is the real value of these professed guardians of our domestic health.

Again, the experiments made on the vitality of pathogenic micro-organisms in water, show that whilst ordinary drinking-water does not form a suitable medium for their extensive growth and multiplication, and that in some cases these forms may undergo more rapid destruction than was formerly supposed, yet, that in the condition of spores, they are extremely permanent in any kind of water, however pure, and that even those of which no spores are known may often be preserved for days or even weeks. We have thus no difficulty in now understanding both how zymotic poisons can be carried by water, as well as how in some cases water known to have been infected has failed to communicate disease.

We have seen that the behaviour of the various pathogenic microbes already experimented with is by no means uniform, and the fallacy of generalising from the results obtained in the case of a single form must be sufficiently apparent. It is essential that the results obtained with any particular organisms should only be made use of in drawing conclusions concerning the particular disease with which it is associated. It is, moreover, of the utmost importance that the great difference in vitality exhibited by bacilli and spores respectively should be most clearly kept in mind, and that in the case of those organisms which are known to exist in both forms, no legitimate conclusions of any practical value can possibly be drawn from the behaviour of the baccilli alone.

Finally we learn that ordinary sewage forms a suitable medium not only for the indefinite preservation of some pathogenic micro-organisms, but also, in some cases, for their rapid growth and multiplication.

DISCUSSION.

The Chairman said the members present must all feel the great importance of the researches which had been so lucidly laid before them. In this, as in every new branch of science, it was of course possible to make a wrong use of the knowledge acquired: to be over frightened on the one hand, or over confident on the other; but no one who had followed these researches carefully could fail to be impressed by the immense strides which knowledge had made in this direction. It might be said that a vast number of organisms might be present in water, and yet do no more harm to man than did the small organisms to the whale that lived on them. But though certain microbes might be harmless, the study of them was part of the great question of sanitation. An offensive smell might not do any serious immediate harm indeed, if offensive smells were fatal, a good many villages in England and towns in Italy would soon be devoid of inhabitants; but ordinary experience showed that a bad smell was generally a warning of some more serious danger which required to be grappled with. If we could remove 99 per cent. of the organisms present in water, it was clear that the chance of the pathogenic one surviving was much diminished. No doubt in the near future we should learn more of the real dangers and safeguards: at present we could but recognise the great value of the results obtained, and the immense importance of continuing those researches.

Mr. Gustav Bischof said it was of course understood that Dr. P. Frankland's paper was based on the assumed efficiency of Dr. Koch's gelatine test. He fully admitted that the rapidity and ease with which results were obtained by the test, the uniformity of those results in parallel experiments, and the nicety of the whole apparatus, formed a great fascination to the experimentalist. All the same, he was expressing not only his own opinion, but that of very weighty bacteriologists, when he entirely disputed that, so far, the efficiency of the test had been proved. In the first place, it was obvious that only those microphytes were cultivated by Dr. Koch's test which could be cultivated under any conditions whatever in gelatine-peptone; Dr. Klein had told them a number of pathogenic and other microphytes absolutely refused to be cultivated in that medium. Next, a great many pathogenic microphytes required for culture a temperature much higher than was possible in following the ordinary test; some requiring as much as 38°C. Time would not permit him to go further into details on that point. Next, Dr. Klein and others had told them that a great many microphytes required weeks—some even months—for their full development. Nevertheless, with the gelatine test observation ceased as a rule about the third day, when the liquifying colonies had developed to such an extent as to render thereafter distinction of colonies impossible. Therefore, we were left in ignorance of what might have taken place in a sample after that period. He thought he had said sufficient to show that there was great doubt as to the reliability of Dr. Koch's test. Then as to the number of colonies, Dr. Klein had referred to a case in which another method indicated as many as 150,000 colonies, while Dr. Koch's test indicated only 5000. And this was what Dr. Percy Frankland called "determination with very considerable quantitative accuracy"—indicating 3 per cent. He could not agree with Dr. Frankland that the teaching of the test rested on a satisfactory basis, if, as admitted by him, no inference could be drawn from the number of colonies as to the wholesomeness of water. Wholesomeness was the object of testing potable water, but under the circumstances, of two samples of water, the one which contained the greater number might even be the more wholesome. Dr. Frankland had repeated on this occasion an assertion which he had made before—viz., that although he did not draw any inference as to the greater or lesser wholesomeness of water before and after a treatment from the difference in the number of colonies, yet that the fact of the reduction of microphytes by a certain percentage admitted of the conclusion that any pathogenic microphytes present would be similarly reduced: and that therefore the danger of infection from them, should they accidentally have gained access to the water, would be correspondingly lessened. He had argued, moreover, some time ago, that neither in respect of size, nor form, nor habits, could pathogenic organisms be sharply distinguished from non-pathogenic organisms. Dr. Koch had, however, distinguished between different organisms, for he had written: "These bacteria, which I have called *Comma Bacilli* on account of their peculiar shape, are smaller than the tubercle bacilli." Was there no difference of size or form there? For all we knew, pathogenic microphytes might exist infinitely more minute than any micro-organisms as yet isolated. Then as to habits. If pathogenic microphytes differed essentially in the temperature, the medium, and the length of time they required for development, surely it could not be said that there was no difference in their habits. Dr. Frankland had himself said in another place that it was highly misleading to apply the results obtained with one set of organisms to the case of another set. Passing now to the pathogenic experiments, he doubted whether any inference could be drawn from the result of infecting a sterilised water with one particular pathogenic microphyte as to what would have taken place if an ordinary natural water were infected with the same microphytes. He could not share Dr. Frankland's doubts as to the effect of crowding out. He would again quote Dr. Klein, who had said he would prepare a sample of water, infected by a dozen pathogenic microphytes, state the names of those microphytes, so that it might be known what to look for, and in nine cases out of ten no one would be able to recognise any given form. With regard to the results of filtration experiments shown on the large diagram before them, he would like to know how it was supposed that the sand acted in retaining microbes—was it a purely mechanical action? If so, then these tabulated results contradicted well-established biological facts, or, if one preferred to put it that way, were contradicted by well-established biological facts. These sand filters were permeated month after month and year after year by water containing a greater or lesser number of colonies. Now, what happened if one took a sample of water containing even only a few microphytes, and stored that water in a sterilised flask protected against any possibility of contamination? Dr. Frankland and himself were agreed that the result was an enormous multiplication of the microphytes. If the microphytes were simply retained in the sand, how was it that no multiplication took place there? He had no hesitation, therefore, in saying that there must be an error somewhere. Again, the percentage reduction tables were entirely misleading. Supposing he had a sample of filtered water containing 100 microphytes, a 90 per cent. reduction would be shown if the unfiltered water contained 1,000 colonies, and 99 per cent. if it contained 10,000. The worse the unfiltered water, the better the showing of the percentage reduction; but after all, one sample of water containing 100 colonies, as far as the numbers of colonies go, was no worse than another containing the same number. He would like to call attention to certain experiments, made, he admitted, before Dr. Koch's method was known, and before many considerable improvements had taken place in the construction of sand filters. Dr. Burdon-Sanderson had experimented on the Metropolitan water supply, with the result that he found that the average "zymotic property" of water was not in any appreciable degree affected by sand filtration. Perhaps something had happened since to alter the conditions; but it was remarkable that a man like Dr. Burdon-Sanderson should have published such statement in an official report in 1870, and that now everything should be quite the reverse. There was a question he would like Dr. Frankland to answer. He had spoken of the large number of microphytes in certain months as the result of the filters being overtaxed. He hoped that this would bring out Dr. Frankland's opinion as to whether the sand exercised a purely mechanical action or not; because if the action were purely mechanical, then the overtaxing would be in direct contradiction to all experience. Every chemist knew that the longer filtration was continued through a filter the more complete was the separation of suspended matter, though of course the yield was reduced; and it was equally well known that with certain precipitates the filtrate had to be returned again and again on to the filter before all suspended matter was retained. With respect to the domestic filter experiments he would say very little. It was remarkable that the results given that evening by Dr. Frankland did not at all agree with those which the same author communicated to the Society last year, when, for instance, in the case of spongy iron, he (Dr. Frankland) had found that after one month's action a water containing 1280 organisms per cc. gave a filtrate containing only 2 organisms per cc., or, as this was within the limit of error of the test, Dr. Frankland found last year that filtration by spongy iron after one month's action gave a sterile water. Nothing had been said as to the conditions under which the experiments were made by Dr. Plagge, and everything depended on that. It was easy to obtain in any such experiment a large number of microphytes; for instance, if one took an ordinary filter with a big reservoir at the bottom, of course multiplication would take place in the water standing in the reservoir. He would say only a few words about the only filters which Dr. Frankland represented as efficient, viz: Pasteur's filter tubes, and the asbestos filters. It was not possible to manufacture these filters absolutely uniformly; hence some would transmit microphytes freely, others be so close in grain as even not to let water pass through. It was, however, quite true that these filters frequently yielded sterile water, but again it was equally true—and he had this from Dr. Koch's own lips—that microphytes very soon grew through the filter tubes, and he might add also through the asbestos filters, when a larger number of colonies might be indicated in the filtered than in the unfiltered sample. One was thus placed in the awkward position of not having a single really trustworthy filter left, if Dr. Frankland's latest conclusions were accepted.

Mr. C. T. Kingzett said this was a most interesting and instructive paper; at the same time, he thought that some of Dr. Frankland's assumptions were not free from danger. In the first place he had drawn too hard and fast a line between pathogenic and non-pathogenic organisms. Many years ago Panum had found (and his results were afterwards confirmed by Burdon-Sanderson) that micro-organisms which were not ordinarily considered pathogenic would, under favourable conditions, produce substances which were poisonous to animals. For instance, sepsin had been thus formed, and sepsin was a body which had considerable toxic effect upon animals. Therefore it was not fair to say that such organisms were not pathogenic to a certain extent. It was too often assumed that microbes had but one mode of life, for instance that the cells of yeast could only live in solutions of sugar, and produce alcohol—in brief, that they could only perform one particular fermentation. But that idea was quite erroneous. The action of the microbes depended upon the mediums into which they were introduced; and if the mediums were changed, the products would necessarily change also. This was not a matter of mere speculation, but had been experimentally demonstrated by him (Mr. Kingzett). It was even conceivable that the *bacillus subtilis* should produce effects corresponding to the *bacillus anthracis* (from which it could hardly be distinguished under the miscroscope) if acting under the same conditions. He did not like to hear any investigator assuming that which passed beyond the limit of ascertained fact. Dr. Frankland had averred, that the organism associated with erysipelas had been proved to be the cause of that disease, and that Koch's *comma bacillus* was the real cause of cholera. He was tolerably well acquainted with the literature of this subject, and he disputed that statement; the assumed connection was in each case a pure matter of influence upon grounds that were open to much criticism. It was true that these micro-organisms had been found associated with the particular disease; there was no absolute proof that they constituted the real causes of the diseases, and as to Koch's *comma bacillus*, it was to be found under many circumstances where there was no question of disease existent. With respect to the inoculation of different waters with the *Anthrax* spores, Dr. Frankland had admitted that in the case No. 3, the experiment had failed through the accidental introduction of other spores on the removal of the stopper. If that was so, how could he be sure, in those other cases where the number had multiplied to a great extent after the first few days, that at some intermediate stage other organisms had not been admitted—especially as dilute sewage was one of the best mediums, not alone for *anthrax* spores, but also for many of the germs which were generally found floating in the atmosphere, and all of which had the power, in common with the *bacillus anthracis*, of liquefying this particular gelatine test. And this led him to a fourth point, which was—had Dr. Frankland proved that the forms which had liquified the test were the spores of the *bacillus anthracis* or not? Apparently he had been satisfied with a microscopical examination, but even if that could be relied upon, it would leave unsettled the doubt that they had been introduced from the atmosphere of the laboratory in the way that he had suggested.

Mr. Johnson suggested that the table representing the effect of filtration upon the water of the different companies would have been improved by the addition of figures representing the rainfall during each month. It had recently come to his knowledge that the month of April, which was proverbially the rainiest month, had for ten years past been one of the driest, and that July had been one of the wettest. Therefore the theory that surface water contamination was the source of impurities seemed to be contradicted. It was more likely that the organic impurities naturally formed by the decay of vegetation would account for the results found by Dr. Frankland. With regard to the experiments on the cultivation of pathogenic germs in drinking water, he questioned whether the quality of the water was not materially altered by the means employed to render it sterile. He did not know what those means were, but if they consisted in raising the temperature, it suggested the possibility that the albumenoid matters which formed the pabulum in which those bodies grew might be readily coagulated by the heat. He thought that the manner in which Dr. Frankland's statements had been received by the members, and the striking concordances elicited, dispelled altogether the idea that his results were not reliable.

In reply, Dr. Percy Frankland said he regretted that Mr. Bischof had spoken in the names of others rather than of himself. He regretted, too, that Dr. Klein was not present, because the greater part of Mr. Bischof's remarks professed to have his authority; and thus in disputing Mr. Bischof's statements he would be brought indirectly into antagonism with Dr. Klein. With regard to the idea that these tests were of no value for forming an opinion as to the number of organisms in water, it occurred to him that their value could be best illustrated by a comparison. Let it be supposed that one had a test for white-faced people, and suppose that this test was applied to the inhabitants of London, and it indicated only the white population: now, although one would undoubtedly miss in such a census of the Metropolis all the coloured inhabitants, yet the absolute result would not materially differ from the correct census taken by the Registrar-General. Similarly, in the case of these waters, what was the probability of any large proportion of those particular and comparatively rare organisms being present which could not be revealed by gelatine culture? Was it likely, for instance, that a sensible percentage of the microbes in Thames water should be tubercle bacilli, which it was quite true could not be cultivated on gelatine? He had no hesitation in saying that the number of organisms of this kind in water must be quite insignificant compared with those which were revealed by gelatine cultivation. It was most necessary to bear in mind that practically all the greater discoveries which had been made in bacteriology during the past few years had been achieved by means of these methods of Dr. Koch's, and that it was almost impossible to overestimate their value. He did not say that the test was perfect, but it was undoubtedly by far the best at present known. With regard to the particular example which Mr. Bischof had brought forward, the case of 150,000 colonies shown by one method against 5000 colonies revealed by the gelatine test, he had often heard that statement before, but always from Mr. Bischof only, and never from Dr. Klein. Dr. Klein had never published that statement in any paper of his own, and had he been present he would like to have asked him by what method that result had been arrived at. There were only two methods in use for arriving at the number of organisms present in any sample of water or other liquid—viz., the method by plate cultivation and the method of Fol and Dunant. By the latter method a certain quantity of water was divided into, say, 50 equal parts, and each part was then put into a tube of sterile broth. The number of organisms present was then deduced from the number of these broth-tubes, which, on incubation, developed organisms, and it was necessary, therefore, to so arrange the experiment that only a portion of the whole number of tubes became infected. Thus if 1cc. of the water in question was distributed through 50 broth-tubes, and of these 10 subsequently developed organisms, it would be assumed that the water contained 10 organisms in 1cc. He (Dr. Frankland) had fully discussed this method in another place (*Journal of the Society of Arts*), and he had shown that it was not only intolerably cumbrous and inconvenient, but was liable to lead to hopelessly erroneous results. With each of these fifty tubes one ran the risk of aërial contamination through fifty exposures to the air. The chances of error were therefore very considerable. In Dr. Klein's laboratory the chances of contamination were found to be so great that he (Dr. Klein) could not perform the operation in the ordinary way by opening the tubes at all, but had to introduce a sterilised pipette down the side of the wool. A series of experiments had recently been made in the Hygienic Institute of Göttingen on the results obtained by this method and by the gelatine method, and in those cases where the Fol and Dunant method yielded trustworthy results they agreed fairly well with the gelatine method. Referring again to this particular experiment mentioned by Mr. Bischof, he would observe that it was only quite recently that one had become aware of the fact that the microphytes in ordinary water often underwent enormous multiplication in a comparatively short time. It was quite unknown at the time that Dr. Burdon-Sanderson's experiments were made, and he had little doubt that it was unknown when this experiment with the 150,000 colonies was made. Numerical experiments of that period must be regarded with great suspicion; and he felt certain that the authors of these experiments would not wish them to be now utilised as they had been by Mr. Bischof. However, even assuming that the gelatine test did not reveal more than a comparatively small fraction of the total number of organisms, its value in estimating the efficiency of filtration was by no means impaired, because the same test being applied to the water before and after filtration, the differential result obtained clearly indicated what was the effect of the filtering process on those organisms which gelatine cultivation reveals. There could, moreover, be no doubt that the process of filtration would deal in just the same manner with any micro-organisms, whether the latter were developable in gelatine or not. Thus the suggestion made by Mr. Bischof that there was some intrinsic difference in size between pathogenic and non-pathogenic organisms was wholly contrary to fact, and the quotation from the writings of Dr. Koch was quite irrelevant and misapplied. Thus Dr. Koch, in describing his *comma bacillus*, wished to give some general idea of its size, and so, instead of saying that it was so many micromillimetres long, etc., he said "it is rather smaller than the *tuberculosis bacillus*;" and from this Mr. Bischof wished it to be understood that Dr. Koch had said that there was a great difference in the size of pathogenic and non-pathogenic organisms! In reply to what Mr. Kingzett had said about the micrococcus of erysipelas, he could only say that Mr. Kingzett was in error in supposing that the evidence as to this micrococcus being the real cause of erysipelas was incomplete. The action of this organism had been perhaps more fully established than that of any other. It had been the practice of some surgeons to artificially produce erysipelas in patients who were suffering from certain forms of cancer, and instead of using virus directly from another patient suffering from erysipelas the disease had by Fehleisen been produced by inoculating carefully prepared pure cultivation of the micrococcus in question. With regard to Mr. Kingzett's criticism of the *anthrax* experiments, and his doubt whether the multiplication indicated in the table was due to the *anthrax* organisms or to some other organisms accidentally introduced, he could say that all the numbers put down in the table were the numbers of undoubted *anthrax* colonies. It was exceedingly easy to distinguish them. The other organisms which had gained access were in the one case a mould, and in the other case a micrococcus, which also formed a totally different colony. With regard to Mr. Johnson's suggestion as to the rainfall being introduced into the tables, that would be a great advantage if these samples were really representative samples of the month, but that unfortunately was not the case. He had only taken one sample per month, and in a month which on the whole might be a dry one the particular sample might have been collected at a rainy time, and *vice versa*. One would have to multiply the number of experiments enormously to give a really average result for each month. As a general rule, however, the river was in flood in January and in the winter months, and comparatively free from flood in July and throughout the greater part of the summer. He must admit that the experiments on the vitality of organisms would be more satisfactory if they could be conducted in unsterilised water; but that would enormously increase the difficulty of the experiments, if indeed it did not render them impossible. Such experiments had been tried by some people, but the results obtained were highly misleading. For the present he thought they could only make use of the results with the sterilised water, and these already established some very important points connected with the vitality of pathogenic micro-organisms in water.

NOTE ON THE ACTION OF ZINC CHLORIDE ON CASTOR OIL.

BY C. R. ALDER WRIGHT, D.SC., F.R.S.

CASTOR OIL has, as is well known, a somewhat peculiar constitution as compared with other oils and fats. Whilst, like these, it is a threefold ether of ordinary glycerol, the acid radical present is of a character different from that of palmitic, stearic, oleic, linoleic acids, etc., in that it contains more oxygen; so that the various acids of oils and fats may be distinguished as belonging to the several families—

$C_nH_{2n}O_2$	—*e.g.*,	Stearic acid $C_{18}H_{36}O_2$: Palmitic acid $C_{16}H_{32}O_2$.
$C_nH_{2n-2}O_2$	,,	Oleic acid $C_{18}H_{34}O_2$.
$C_nH_{2n-4}O_2$	,,	Linoleic acid $C_{18}H_{32}O_2$ (according to earlier experiments, $C_{16}H_{28}O_2$).
$C_nH_{2n-2}O_3$	,,	Ricinoleic acid $C_{18}H_{34}O_3$.

Accordingly, the glyceride of ricinoleic acid (the main constituent of castor oil) differs in numerous physical and chemical characters from the glycerides of the other commonly-occurring fatty oils and acids, more particularly in its specific gravity and solubility in alcohol and other menstrua. Inasmuch, however, as ricinoleic acid belongs (like oleic and linoleic acids) to the series of non-saturated substances, therein differing from stearic acid and its homologues, it possesses, in common with the former, the property of becoming polymerised by contact with certain agents—of which nitrous acid or materials generating it is one of the best known—and thereby altered in physical condition to an extent depending somewhat on the nature of the polymerising agent, and the extent and duration of its action, etc.

Whilst experimenting in conjunction with Dr. Alexander Muirhead upon actions of this class, it was observed that zinc chloride in concentrated solution, or as fused hydrated crystallised salt, possesses a most marked thickening and solidifying action upon certain oils, and more especially upon castor oil, so that under suitable conditions this latter is converted into a horny or gristly indurated mass, which, when freed from zinc chloride by thorough washing with water, is capable of various useful applications, more especially as an ingredient in mixtures intended as covering and insulating materials for electric leads, etc. According to the proportion of zinc chloride used and its concentration and the temperature employed, the degree of solidification and induration effected can be controlled at will, the consistency of the product varying from a somewhat thicker and more viscid or semi-solid oil up to a tough, leathery, cartilaginous mass, resembling rasped horn. The most effective treatment consists in evaporating down zinc chloride solution until the boiling-point rises to near 175° C., at which temperature the degree of hydration is not far from that corresponding with the formula $ZnCl_2,H_2O$. This concentrated fluid is then cooled to about 125°, and well intermixed by agitation with one-third its weight of castor oil at about the same temperature. The oil rapidly becomes converted into a thick clot, which separates from the fluid zinc chloride in lumps resembling bullocks' liver in appearance, but becoming a mass of nearly white cartilaginous shreds when digested with water and vigorously agitated therewith. The zinc chloride used is practically all recovered, the majority in the form of hot fluid separating spontaneously from the clot and ready for immediate use over again, and the remainder in the form of aqueous solution washed out from the clot and simply requiring evaporation down to the proper strength.

The cartilaginous shreds thus obtained differ much in their general physical character from the original unconverted castor oil, being practically insoluble in the various menstrua in which the latter dissolves. The glyceridic character, however, is not wholly destroyed; thus notable quantities of impure glycerol can be obtained by long-continued boiling with alcoholic potash of the shreds, previously completely freed from all traces of unconverted oil by repeated digestion with carbon disulphide.

IMPROVED FILTERING FUNNELS.

BY B. NICKELS, F.C.S.

The usual devices for accelerating filtration are well known to chemists, but they all have the disadvantage of leaving certain parts of the filter paper without any support at the back, causing thereby a grave risk of breakage of the paper. Fig. 1 represents a double funnel, the inner attached to the outer by means of suitable "ribs" or "projections" placed at intervals. The inner funnel is perforated with holes in a downward direction. Fig. 3 is similar to Fig. 1, with the exception that the space between the two funnels at the top is closed, with a stop-cock for admission of air, and for cleaning purposes. Ordinary filtration with these funnels is greatly quickened, as the filtrate has a free exit through all the perforations. It is frequently desirable to wash the back of a filter paper; but this is risky, and always unsatisfactory. With the improved filter, however, it is only necessary to attach a piece of tube, with a stop-cock, to the bottom of the funnel, and when the filtrate has drained away, to close the cock and fill the jacket with the water or other wash liquor, which immediately makes its way, through the holes, to the *back* of the filter paper, quickly and thoroughly washing the same. Fig. 3 is for use in connection with aspirator water or other pump: the usual hollow platinum cone is unnecessary: the perforations in the inner funnel, being very small but numerous, admit of a high vacuum being employed without risk of breaking the paper, and filtration is conducted with very great rapidity. Dialysing, as usually conducted, is troublesome, owing to the difficulty of making a tight joint with the parchment paper to the proof containing the liquid to be dialysed. All that is necessary with this funnel is to attach a tube and stop-cock to the end, and place a piece of parchment paper folded as a filter paper in the inner funnel, but projecting about one inch above the top. The liquid to be dialysed is placed therein, and the jacket filled with distilled water, which may be drawn off as it becomes charged with the products of diffusion, and replaced by a fresh supply. The quantity of water is thus minimised, which is an important feature in this operation. The funnel is well adapted for filtration of volatile liquids, and may supersede the somewhat complicated apparatus usually employed. The funnel is placed through a cork, and tightly inserted into a vessel to receive the filtrate. The filter paper having been inserted in the usual manner, the liquid to be filtered is poured therein in the ordinary way, and the *whole top of the funnel* covered with a disc of ground glass, underneath which may be placed a disc of indiarubber, if the joint is not tight enough. As the filtrate enters the vessel, the displaced air finds its way to the top of the funnel jacket, and entering the inner funnel through the holes, causes filtration to proceed without cessation or loss of volatile liquid filtrate.

ON MOISTURE AND FREE ACID IN SUPERPHOSPHATES AND SIMILAR FERTILISERS.

BY JOHN RUFFLE, M.R.A.C., F.I.C., ETC.

Moisture in superphosphates is usually determined by exposing a weighed portion to 212° F., cooling, reweighing, and the loss found considered as moisture, and so stated in all analysis. A suspicion, however, exists in the minds of some chemists that if left too long at 212° F., some of the water of combination may be driven off, and so the result be stated too high; and commonly a limit of about one and a half to two hours is accepted as the time to leave the portion at 212° F. Some operators put the portion into the water-oven and leave it overnight; this has apparently one merit—*i.e.*, that the total loss of 212° F. is then constant, and any error be a constant one, but whether such be an error or no, no one knows.

In preparing a sample for analysis it is most usual to rub it into a paste with a pestle and mortar. Some chemists take a part of this paste and expose it to 212° F., whilst some take the manure in the natural state, but in neither case with any definite knowledge as to whether the pasting does or does not affect the result, and, if affecting it, then the degree is unknown. This article is therefore put forward as a contribution on the subject, and as an assistance towards a satisfactory method of dealing with a vexatious question as yet unattacked.

Some samples of ordinary superphosphates were selected from large heaps and maintained at various temperatures until practically constant, the loss noted, and the soluble and total P_2O_5 estimated before and after drying.

CAROLINA SUPERPHOSPHATE.

	100–120° F.	160–180° F.	212° F.	300° F.
Loss..................	12·92	15·42	16·10	17·93
Soluble P_2O_5, theory	15·74	16·20	16·34	16·70
,, ,, found	15·02	15·11	14·45	10·26
,, ,, loss	0·72	1·09	1·89	6·44
Total ,, theory	16·25	16·72	16·86	17·24
,, ,, found	16·19	16·52	16·63	17·10
,, ,, loss	0·06	0·20	0·23	0·14

SOMBRERO SUPERPHOSPHATE.

	100–120° F.	160–180° F.	212° F.	300° F.
Loss..................	11·96	11·20	15·50	17·62
Soluble P_2O_5, theory	20·17	20·69	21·01	21·55
,, ,, found	19·90	20·07	19·50	11·20
,, ,, loss	0·27	0·62	1·51	7·35
Total ,, theory	20·13	20·96	21·29	21·80
,, ,, found	20·43	20·85	20·69	20·92*
,, ,, loss	—	0·11	0·60	0·88

The above results show that the soluble P_2O_5 is affected as the temperature rises, and that even the total P_2O_5 is affected in a minor degree. Some superphosphate was therefore dried without rise of temperature over oil of vitriol under a bell glass till constant.

	Carolina Super. over H_2SO_4.	Sombrero Super. over H_2SO_4.
Loss	14·84	13·56
Soluble P_2O_5, theory	16·09	20·54
,, ,, found	16·04	20·47
Total ,, theory	16·61	20·81
,, ,, found	16·61	20·90

These results show that drying a superphosphate without rise of temperature does not affect the soluble nor total P_2O_5. Such drying over H_2SO_4 was, however, too tedious, occupying about fifteen to eighteen days.

The operation at 212° F. was again tried to see if some stated period could not be found at which the result could be accepted. (See tables on top of next page.)

In their natural state these superphosphates contained—

	Carolina.		Sombrero.
Soluble P_2O_5..........	13·71	....	17·76
Insoluble ,, ...	0·44	....	0·23
	14·15		17·99

The figures show that a drying of from five to seven hours was necessary to arrive at anything like constant results, and that from a quarter of an hour upwards the soluble P_2O_5 was affected, and no period was discernible at which the result could be finally accepted.

Some portions of superphosphate from large stocks in heap were then dried at 212° F. in the natural state, and also after beating up in pestle and mortar, giving results as below:—

	Carolina Superphosphate.		Sombrero Superphosphate	
	Natural State.	Beaten up.	Natural State.	Beaten up.
½ hour ..	18·51	7·27	17·44	7·76
1 ,, ..	18·68	8·24	17·45	11·0
2 ,, ..	18·73	10·17	17·68	13·63
3 ,, ..	—	11·11	17·89	14·73
4 ,, ..	—	13·33	17·87	15·88
5 ,, ..	—	—	—	16·57

It is evident here that the "natural state" or "beaten up" vitally affects the loss at 212° F.

The loss at 212° F. being so unsatisfactory, it was desirable to show if it were all moisture or if including water of combination, and if so how much.

To help to clear this up some superphosphates were prepared of known composition, the raw materials analysed beforehand, the losses in mixing noted, and the products carefully weighed and preserved. These superphosphates were made from ordinary raw materials, and, from long experience with this class of compounds, and the agreement of the results obtained with these preparations in comparison with those obtained from superphosphates made on the usual wholesale scale, the writer has confidence in putting forward the results as reliable, and in accordance with the properties and behaviour of ordinary superphosphates.

---

* 1·018grms. of this was fused with "fusion mixture," and the total P_2O_5 determined, obtaining 21·68 per cent. instead of 20·92 per cent., showing, therefore, that the total P_2O_5 had been affected, but was recoverable as ortho-phosphoric acid.

The loss in mixing was in each case accepted as due to carbonic acid and water. Of course, in some cases a little hydrofluosilicic acid was driven off, but any loss on this head was not enough to disturb the result, and any attempt to ascertain the loss due to this would have been unreliable.

Four superphosphates were prepared with Carolina, Sombrero, Spanish, and Curaçao phosphates respectively, and gave superphosphates in good, fair condition:—

(⁴) „ „ $MgOSO_37H_2O$

With the above superphosphates experiments were carried out as to effects of exposure to 212° F.—What is soluble in water? etc.

The above superphosphates of known composition were exposed to 212° F. for various periods in natural state and beaten up (November, 1886). (See table on top of next page.)

These results, after exposure to 212° F., show that if exposed in natural state a loss is suffered well within the usual time of exposure, which must include some of the water of combination, and give results much too high; whilst if exposed in the beaten-up state, the results drag a long way behind, need twenty-four hours to overtake the natural state, and are not certain to do this even then, as is instanced in the "Carolina," which is only 18·60 against 20·22 after 24 hours.

The soluble P_2O_5 is in note-books and in practice held to exist, combined with two molecules of water and one molecule of lime, but is this really so? If such be the fact, then on dissolving out the soluble P_2O_5 with water, there would be found as much CaO present as would combine with the soluble P_2O_5, and a little more from the calcium sulphate dissolved. The superphosphates were mixed with their own weight of water, and allowed to filter, and the filtrate examined, with the results tabulated in second table on next page.

From these results it is manifest that, whilst some of the soluble P_2O_5 may be present as monocalcium, the larger portion must be present as free acid—*i.e.*, $P_2O_53H_2O$, especially when we bear in mind that some of the lime present is doubtless combined with

24	20·22	18·60	18·95	18·89	17·74	17·80

the SO_3 found. Also the SO_3 found is in smaller proportion to the P_2O_5 than would be if the soluble iron, soda, alumina and magnesia were sulphates; so that the SO_3, not being present in enough quantity to combine with all these, cannot be considered present as free SO_3, and in particular in presence of so much more lime than it needs, and the known solubility of calcium sulphate. This is additional ground for accepting that the free acid is phosphoric.

Having shown that the existing soluble P_2O_5 is not entirely present as monocalcium phosphate, and that exposure to 212° F. drives off too much, it remained to arrive at some convenient results which should agree with an apportionment of the existent water amongst the constituents present. To this end drying was tried over H_2SO_4 under a bell jar, and the same in vacuum of an air-pump; over sodium hydrate, sodium chloride, sodium carbonate, potassium carbonate, magnesium chloride, etc., etc., in the vacuum of an air-pump; also with dry calcium chloride ditto. All these various experiments gave results too irregular for acceptance, save those with calcium chloride, which, approaching to a definite formulæ, with variations as may be expected in a body of such variable composition as a superphosphate, and yet following in figures some of the known properties of these bodies, offers a plan for estimating the true moisture —that is, the adhering, uncombined water.

	Carolina.	Sombrero.	Spanish.	Curaçao.
Soluble P_2O_5 found ..	10·96	13·12	14·15	16·91
" CaO* " ..	1·58	3·18	0·67	3·00
" SO_3 " ..	0·17	0·38	0·56	0·44
* Amount thoretically needed to form monocalcium phosphate with the soluble P_2O_5 found	4·32	5·17	5·53	6·78

To make a rigidly accurate assignment of the water, combined with each constituent present, is practically impossible, but the main components being water, soluble P_2O_5, lime and sulphuric acid, we may deal with these, and disregard the smaller matters, and if the final results approximate to the results found, consider the method put forward as sustained, particularly as these important constituents, with the insoluble silicious matters, make up 91·12, 93·15, 95·69, and 97·70 per cent. of the totals respectively.

(*a.*) From the soluble P_2O_5 and soluble CaO found in the filtrate, calculate how much soluble CaO is proportional to the total per cent. of soluble P_2O_5 in the manure, and this calculate into monocalcium phosphate.

(*b.*) The soluble P_2O_5, not so combined, calculate into free phosphoric acid.

(*c.*) From the insoluble P_2O_5 calculate the insoluble tricalcium phosphate.

(*d.*) The whole of the SO_3 calculate into calcium sulphate, combined with one molecule of water.

The results obtained by the exposure to dry calcium chloride in vacuum of an air-pump were :—

	Feb. 1.	March 3.	March 23.	April 25.
Carolina Superphosphate	14·38—14·12	13·57—13·55	13·17	12·86—12·90
Sombrero Sup'rphosphate	15·65—15·81	15·28—15·31	14·79	14·45—14·30
Spanish Superphosphate....	14·50—14·48	13·89—13·91	13·46	12·96—12·85
Curaçao Superphospate	—	12·37—12·21	11·89	11·38—11·22

It is known practically that superphosphates, if kept in a heap, bag or jar, gradually improve in condition—that is, become drier to handle; and it is interesting to notice in the above figures that as every few weeks go on the amount of uncombined water slightly decreases, thus becoming a measure of the drying which is proceeding by the calcium sulphate gradually absorbing more water than it had at first.

The amounts of "moisture by calcium chloride" put down above are the amounts obtained up to the date when the filtrates were examined; they will, therefore, refer to the conditions the superphosphates were under at such time. Owing to the acid products present it may be that the calcium sulphate does not at once absorb the whole of its water, but does so gradually; if so, some of its water, as calculated, would come out on drying, and so be reckoned twice. To such may be due the high result obtained in some cases.

However, from the close approximation of the results obtained to those calculated, and bearing in mind the complex composition of superphosphate with its known variation in condition, the method proposed may be accepted.

A convenient way is to weigh out 2 to 5grms. in its natural state on a double watch-glass, place under air-pump, exhaust, and leave for 18 to 24 hours, then weigh. This period is sufficient for practical purposes, and is the one here adopted. A shorter period suitable for any one day's work is not always enough; the portion can therefore be left overnight.

To show the effect of time the results below are given as obtained :—

LOSS BY THE VARIOUS SUPERPHOSPHATES IN VACUUM OF AN AIR-PUMP OVER DRY CALCIUM CHLORIDE.

with practical observation, is not at all indicated by exposure to 212° F. Thus :—

	Carolina.	Sombrero.	Spanish.
Loss by exposure to 212° F. ...	19·11	18·76	17·18
Ditto two months afterwards ..	19·79	18·69	17·40

One precaution is advisable—*i.e.*, to have an air-pump which will keep its vacuum for 24 hours. This can be readily obtained, but many pumps sold will not do it.

Ammoniated Superphosphates.

The treatment of Peruvian and other guanos with sulphuric acid, and the treatment of phosphates intermixed with sulphate of ammonia or other more or less ammoniacal matter, is in each case essentially only a superphosphate ammoniated by the ammonia added, and these form a very large proportion of the chemical manures produced. Having proposed a method for the estimation of the moisture in superphosphates, it is desirable to see how far such method could be used in the ammoniated superphosphates. If in both of these classes, then the method could be generally adopted for artificial, or rather for chemical manures produced by treatment with sulphuric acid in the dinary way.

Three mixtures were prepared by using curaçao phosphate, sulphate of ammonia, H_2SO_4, and water, all of which were carefully examined beforehand, weighed off, losses in mixings duly noted, and the final product kept for trial and experiment. The mixtures were intended to represent ammoniated superphosphate, containing respectively 3%, 6%, and 9% of ammonia (NH_3).

The analyses of these were as follows, all the H_2O of all the constituents being classed as water, and the SO_3 from all sources put together :—

COMPOSITION OF THE AMMONIATED SUPERPHOSPHATES.

	3% NH	6% NH_3	9% NH_3
Water	21·63	20·71	20·33
Soluble P_2O_5	15·02	13·05	11·66
Insoluble P_2O_5	2·40	1·77	1·01
Lime (CaO)	21·43	18·44	16·72
Sulphuric acid (SO_3)	31·40	35·62	38·45
Ammonia (NH_3)	2·98	6·15	8·87
Magnesia, alkalis, etc	4·60	3·82	2·63
Insoluble silicious matters	0·54	0·44	0·33
	100·00	100·00	100·00

These were each mixed so as to make good, fair-conditioned manures.

Each was then, as in the case of the plain superphosphates, mixed with its own weight of water, filtered, and the filtrate examined. The first table on next column gives the results.

It is at once evident, from the very wide divergence between the CaO found and the CaO of theory, that substantially monocalcium phosphate is not, and can not, be present in the manure.

Also it is highly interesting to notice the relative amounts of SO_3 and NH_3 found. The NH_3 was put in wholly in combination with SO_3, and one would at first sight naturally expect to find it still combined with SO_3, so that whatever changes occurred in the manure the SO_3 would, at anyrate, be present in sufficient amount to combine with NH_3; but such is not the case, as is seen by a comparison of the SO_3 and NH_3 found :—

	Filtrates of the		
	3 per Cent.	6 per Cent.	9 per Cent.
Soluble P_2O_5	13·12	13·08	12·10
" CaO....................	0·31	0·10	0·14
" SO_3	1·18	7·44	10·70
" NH_3	2·29	4·19	5·10
The above P_2O_5 to form monocalcium phosphate would need of CaO	5·17	5·15	4·77

	3 per Cent.	6 per Cent.	9 per Cent.
SO_3 found	1·18	7·11	10·70
Would need of NH_3—theory	0·50	3·16	4·50
NH_3 found	2·29	4·19	5·40

Here the NH_3 was more than the SO_3 could combine with, and the only other acid present was the P_2O_5, therefore the P_2O_5 must have been liberated so as to act as a free acid, and have attacked the ammonium sulphate so as to drive out some of the sulphuric acid and take its place.

Also the P_2O_5 is much more than is needed to combine with the small amount of CaO present and the remaining or even all the NH_3; and there are no other constituents to combine with the P_2O_5, therefore here also the free acid is phosphoric.

To arrive at the proportionate amounts of the various bodies present we can proceed thus :—

(*a.*) From the CaO found in the filtrate calculate the amount of CaO combined with the percentage P_2O_5 so as to form monocalcium, in proportion between the P_2O_5 in the filtrate and the percentage P_2O_5.

(*b.*) Calculate the insoluble P_2O_5 into insoluble tricalcium phosphate.

(*c.*) The CaO of the monocalcium and of the insoluble phosphate add together, the sum subtract from the total CaO, combine the remaining CaO to calcium sulphate plus one molecule of water.

(*d.*) The SO_3 of the calcium sulphate deduct from the total SO_3, and the remaining calculate into ammonium sulphate.

(*e.*) The ammonia of the ammonium sulphate deduct from the total ammonia, the balance calculate into ammonium phosphate.

(*f.*) Add together the P_2O_5 of the ammonium phosphate and of the monocalcium, the rest calculate into free phosphoric acid.

Tabulate these (see table on top of next page) and set out the H_2O combined.

These manures were also dried over dry calcium chloride in the vacuum of an air-pump, and the result obtained at about the same date as the making of the filtrate is put down above as "moisture by calcium chloride."

The water combined off, deducted from the total water, leaves amount of 8·99, 7·39, 7·33 per cent., which, reduced by the "moisture" found, leaves respectively 1·09, 2·81, 3·02 per cent. of water unaccountable for. Now it is seen that such figures approximate to the amounts of water in the ammonium sulphate of 3, 6, and 9 per cent. respectively.

By calcium chloride.

On adding a strong solution of ammonium sulphate to gypsum it sets to a hard crisp mass, different in texture to gypsum hydrated with plain water, and this hard crisp condition is also a characteristic condition of ammoniated superphosphates. From facts and the approximation of the foregoing figures, it is probable that a double sulphate is formed appropriating to itself one molecule of water for combination, in which case the whole of the water present is satisfactorily accounted for.

The gradual dryings of the samples noticed in the plain superphosphates is also observed in these fertilisers :—

	3 per Cent.	6 per Cent.	9 per Cent.
March 9, after 24 hours	8·81—8·93	4·98—4·95	5·15—5·41
March 24, after 24 hours	8·51	4·58	5·03
April 25, after 24 hours	7·90—7·91	4·11—4·01	4·37—4·31

The effect which the length of the exposure to the chloride has upon the result is shown in the following table :—

	3 per Cent.	6 per Cent.	9 per Cent.
After 2 hours	8·20	4·38	4·94
After 6 hours	8·30	4·51	5·03
After 24 hours	8·51	4·58	5·03
After 48 hours	8·56	4·63	5·03
After 72 hours	8·56	4·65	5·11

Whilst the "moisture" by the method proposed was as given, the loss by exposure was as shown beneath :

	3 per Cent.	6 per Cent.	9 per Cent
Loss after 212° F., 3 hours	11·65	12·15	9·18

It is instructive and novel to compare the loss at 212° F. with the known water in the samples, and to see where the loss has arisen, and to notice how in this, the usual way of proceeding, the water of combination is attacked.

The results over dry calcium chloride in air-pump vacuum are confirmed by those over dry calcium chloride under a simple bell jar, but the latter are much longer in becoming constant, needing in fact from 300—400 hours.

Bearing in mind that the alkalis and the magnesia are not determined, and that these throughout the whole series of these experiments will have an influence upon the moisture, though of too irregular a nature for their extent to be accurately measured, whilst the important and extensive constituents are the water, soluble P_2O_5, the SO_3, and the CaO, which have been dealt with and assigned to their places with as fair an approximation as can be expected in a compound which is continually and progressively altering in some small degree, the method proposed for estimating the "moisture"—*i.e.*, the uncombined adhering water by exposure to dry calcium chloride in the vacuum of an air pump—is one to be accepted.

Only one molecule of water has been assigned to the calcium sulphate in the above calculations, because of all the various experiments tried by drying in presence of calcium chloride, sodium hydrate, etc., none left sufficient water in the manure to supply the calcium sulphate with more than one molecule; the inference, therefore, is that one molecule is all that is combined with the calcium sulphate.

The writer desires to express his indebtedness to Mr. Thomas W. B. Mumford for the kindly practical assistance with which he has helped on this research.

Liverpool Section.

Meeting held Wednesday Evening, May 4, at the University College.

DR. J. CAMPBELL BROWN IN THE CHAIR.

Mr. J. W. Macdonald exhibited a few samples of scale and powder taken from the external shells of boilers, which he thought would be of interest to members. He said that the boilers he had had to do with had no external scale until recently, but during the last five weeks they had noticed the grey scale, which was about $\frac{1}{16}$in. thick, and on the scale a grey powder, $\frac{1}{8}$in. thick. On analysis, the scale was found to consist chiefly of ferric sulphate. It was very difficult to remove, and required a great deal of hammering. Under the scale the boiler plate was as bright as new silver. He could not be certain that the scale had been formed at the expense of the boiler plates; probably the first of it was from the metal, but the rest of it had the appearance of being deposited in layers from the outside. No doubt they had been getting some bad slack, containing an undue amount of sulphur and pyrites. His theory of it was that the sulphuric acid, having been oxidised by the presence of nitrates in the coal, condensed on the boiler-plates, which would not be much hotter than the water on the other side of them. The fine flue dust, which contains a considerable quantity of oxide of iron, would then stick to the condensed vitriol, and thus layer by layer of the sulphate might be formed. The powder, strange to say, had not the same composition. Its chief ingredient certainly was sulphate of iron, but this was mixed up with the other constituents of coal ash. Notwithstanding the brightness of the metal below the scale, it could not be said that there was any apparent wasting of the plates. He would be glad if any of the members could throw any light on this matter, and send their experience to the Journal. He himself thought it showed the objection to using coal with much sulphur. Apart from the injury of the plates by the sulphuric acid, the loss of heat, owing to the presence of $\frac{3}{16}$in. of a non conducting substance, must have been considerable. Their boilers were fed by mechanical stokers, but he could not say whether the better combustion thus obtained helped the formation of sulphuric acid more readily than hand firing. He had made many inquiries, both from sellers and consumers of large quantities of coal, but could not hear of any similar experience, excepting in their works in London, where stokers, but different slack, were used. In this case, however, there was no scale, only a *dark* powder, resembling in composition the grey powder, but containing more carbon (only 2½ per cent., however). This powder was easily removed by a hard wire brush. All boilers were more or less covered with a dark powder, and which was generally assumed to be soot. He thought it was more likely to be chiefly sulphate of iron, and that consumers should pay more attention to the quantity of sulphur in the coals they used. The following were the analyses of the three samples referred to; the grey powder contained copper, but it was not estimated:—

◆◆◆

MANUFACTURE OF ARROWROOT STARCH IN ST. VINCENT.

BY J. W. MACDONALD.

As we have lately been treated to a very interesting paper on starch manufacture from Indian corn, it was suggested to me that we might with advantage continue our discussions on this subject by learning something of its manufacture from another raw material, arrowroot, or, as it is known in botany, Maranta Arundinacea. This plant is essentially a starch-producing plant, the starch existing in it in almost absolute purity, and no other use having been found for it, as far as I am aware, excepting for feeding cattle. I have long felt, and this was also dwelt upon by our Chairman in his discussion on Dr. Archbold's paper, that it was a great waste of valuable nitrogenous matter to manufacture starch from such materials as maize, wheat, rice and potatoes, which in themselves form a large proportion of the food of man. We have around us large masses of half fed human beings, nevertheless we daily destroy hundreds of tons of valuable food in the manufacture of starch, etc. I feel sure that as the world advances and becomes more populated, a more conserving spirit must prevade our manufactories, and only such raw materials be used as will cause the least waste of matter; countries, too, that are best suited by natural forces for the production of certain commodities, will have to carry out the intentions of nature. We will not then have such anomalies as Europe trying, by the aid of Governments, to supply the world with sugar; for nature's sugar plant is the sugar cane, and its home, the tropics.

Arrowroot is also a native of the tropics. The island of St. Vincent in the West Indies has taken the foremost part in its growth and production; a fair quantity is also made in Natal, and smaller quantities in India, Fiji, Queensland and other countries. Formerly, the Bermuda Islands produced a good deal, but, as there is very little arable land and a scarcity of water, and the inhabitants having turned their attention to growing early vegetables for the New York markets, arrowroot is gradually being given up.

In St. Vincent the plant grows two to three feet high. It is a weak fibrous stalk with six to eight arrow-shaped leaves resembling the leaves of the lily. When the root is ripe, these leaves fall and wither. The plant flowers but does not bear seed, and is therefore propagated by the root. This can be done in two ways, either by pulling the green stalks, trimming off the long hairy roots, and setting them six inches apart in fields previously prepared for their reception, or, as is most generally done, by returning to the soil the upper end of the root, which is hard and fibrous and contains very little starch. As the fields are dug up, the labourers pick out the roots and break off these top pieces four to six inches long, and bury them in holes six inches apart and a few inches deep. In this way reaping and planting go on simultaneously. Care must be taken, however, to avoid returning to the soil small thin weak roots. The roots commence to grow in about a fortnight, but, to avoid choking, the fields have to be weeded two or three times. In about ten to twelve months the roots are ripe, and are then twelve to eighteen inches below the surface. If they are reaped before being properly ripe, the next crop suffers and frequently takes fifteen months to mature, and the fields require to be frequently weeded. With careful attention and manuring fields will produce crops for over 20 years. The arrowroot is a very hardy plant, and will continue to grow up and die down for years after its cultivation has ceased in a field. The roots are long and tap shaped, and are jointed at intervals of three quarters to one inch. In the soil they are protected by a fibrous covering which grows from each joint, the folds overlapping each other to the end of the root. Full-grown roots are from ten to eighteen inches long, the most starch being found in the lower or youngest end.

The first part of the manufacturing process is to soak the roots in water to soften the covering and the adhering earth. They are then stripped of the covering and washed, and thrown into a second or rinsing tank. When thoroughly clean they are taken to the pulping machine. The skin is said to contain a resinous matter which gives a yellow tinge and unpleasant flavour to the starch, if the latter is not well washed. In former times the roots were very carefully skinned with German silver knives, before being pulped. This is said to have produced whiter starch, but as it was so laborious and expensive, it was discontinued. The skinned roots were pulped by subjecting them to great pressure by passing them through an upper, and then a lower and much closer, pair of polished brass rollers, to break the starch cells. The method of pulping now generally adopted is to feed the clean unskinned roots against a fine saw grater very similar to a potato grater. It is a solid cylinder of hard wood about 23 inches diameter and seven inches wide. Slits are made by a saw from end to end of the wood at half-inch intervals. Saw blades having six to ten teeth to the inch are then fitted into the slits, and the whole immersed in water to swell the wood and fix the saws. The grater is now fitted into its place very close to a wooden feeding bed. As it revolves several hundred times per minute it tears the roots into shreds. A great deal, however, depends on the fineness of the teeth and the velocity of the drum.

On account of the very fibrous nature of the pulp there is considerable difficulty in the sieving or separating of the starch from it. The fibres readily gather into lumps and enclose the starch, so that hand sieving, although very tedious, has to be resorted to. The pulp is first run into a box or sieve, the bottom of which is a sheet of copper or tin punched with holes about one-fifth inch diameter. While water flows on, the contents are kept thoroughly agitated by hand, until all the starch has been washed out. While one strainer full is being washed, another is being filled so that there should be no delay. However careful one is, there is a loss of starch in the fibre owing to the presence of small bits of the roots which have escaped pulping.

In one factory, instead of the above strainer a tin-lined copper cylinder has been tried. The cylinder was stationary, its under side being pierced with holes, and, inside, paddles or beaters revolved at great speed amongst the pulp and water, until the latter flowed away free from starch. The washed fibre was then removed and a fresh charge of pulp put in. This, however, has been discontinued. In another factory, a half cylinder, also stationary, is in course of erection. Its under side is also pierced with small holes, but there is a slide under this to open or close at will. Inside, there are rakes attached to two shafts, which move in opposite directions and cause the rakes to oscillate very rapidly between each other, thereby keeping the fibre always open. The starch water is let out, more water run in, and the operation repeated until the starch has ceased; then the fibre is taken out. The great objection to any mechanical washer is the tendency of the fibre to accumulate on the agitators and break them. I do not know at present of a single mechanical washer being in use. To get over this difficulty it has been proposed to chop up or slice the roots into small short pieces, and either rasp them or pass them through metal rollers or mill-stones, so that the thin disintegrated pulp may flow over mechanical sieves. I do not know if this plan has yet been tried. Although causing a loss of starch, the present method of rasping avoids an undue pulverising of the soft yellow fibre, and so gives a very white starch without much further trouble.

From the fibre strainers the starch water flows consecutively through a series of brass wire sieves of 40, 80, and 100-meshes; each of these retain small fleshy bits of unpulped root. From the last sieve the water runs into the settling cisterns, which are preferably lined with white glazed tiles to avoid accumulation of slime.

A portion of the fibre collected on the finer sieves is used for feeding the animals on the estate, the remainder and all the coarse fibre are used as manure. For this purpose it is left in heaps until it decomposes, after which it is distributed on the fields along with pen manure. Sometimes also ashes and guano are used. The waste water from washing the starch contains a considerable amount of vegetable matter, and gives good results where it is run on the fields, but the extensive application of this is not practicable. After the starch has settled in the cisterns the water is run off and more added, the whole is stirred up and again allowed to settle. This generally suffices to dissolve out soluble matters. At night all the cisterns are drained, and the starch is dug out and taken to a mixing box, where it is mixed with a small amount of water, then run through another fine sieve into the separating pans. These are small round galvanised cisterns with smooth perpendicular sides. When filled, the starch milk is stirred round with a small oar until it is in violent circulation. The oar is withdrawn and the cisterns left until morning. The stirring has the effect of separating the starch from any remaining impurities. These, being of less specific gravity, settle last and therefore on top of the starch. Next morning the water is drained off, and the light impure starch scraped off the surface. If the earlier parts of the process are carelessly done, this separation may have to be repeated before the starch is quite pure. The impure surface starch contains a large proportion of starch entangled in very fine particles of fibre and broken cell walls. Although this can be dried and exported as an inferior starch, it is generally given to the labourers as a perquisite. It is used in various forms as flour. Poultry and pigs are also fed with it. Weak caustic soda extracts a colouring matter from it, but also precipitates a yellow substance, making it very difficult to separate the starch from it in a pure state.

The pure starch in the separators is now taken out in blocks, and placed on trays for about twelve hours to drain and harden. It is then broken into smaller pieces, and taken to the drying house, where it is air dried. This building is open on all sides for free circulation of air. It is surrounded, however, with galvanised wire to keep out the small birds which hover about. Inside, there are a series of wire shelves over large shallow wooden trays. The top shelf is made of very open wire, the next is closer, and so on, the lowest being the closest. The wet lumps of starch are placed side by side on the top shelf, where they remain until by the action of the air they crack up and fall through on to the next shelf. In time, the whole falls through the lowest shelf, and is in a fine granular state, ready for packing. It contains from 14 to 17 per cent. of water. In cold wet weather the starch dries very slowly, taking sometimes as long as two weeks. During this time, if the starch has been imperfectly purified, the lumps get sour, and become yellowish. Indeed, the whole process must be as rapid as possible. In the settling cisterns especially, if the starch is left in contact with the impure water too long, its whiteness is affected. The crop lasts from October to May. The name "arrowroot" is, I think, derived from the Indian word, Ara-ruta, or "mealy root;" but some say that this root has been confounded with the maranta galanga, which was called the arrowroot on account of its bruised roots being used as an antidote to the poison of the Jatropha Manihot, which was used for poisoning their arrows. I may say that tapioca starch is obtained from this poisonous root. The poison, however, is contained in the juice only, and is destroyed by heat.

Regarding the yield of arrowroot, an acre will produce 13,000 to 15,000lb. of roots, according to the season: in wet seasons the roots are heavy and moist, and give less starch. A fair average yield is 22cwt. air-dried starch, with 14 per cent. water, per acre, or about 19 per cent. on good roots. I have no doubt that this will be considerably increased by the use of much-needed improved pulping and sieving machinery. The roots that I have analysed got slightly dried in transit, so that they show a rather high amount of starch. The analysis, however, will give an idea of the constituents of the roots. In some respects it differs from an analysis by Benzon, stated in Ure's Dictionary, and which I append:—

	J. W. M.	Benzon.
Starch	27·07	26·00
Fibre	2·82	6·00
Fat	0·26	0·07
Albumin	1·56	1·58
Sugar, Gum, &c. ..	4·10	0·60 (Gum)
Ash	1·23	0·25 ($CaCl_2$)
Water	62·96	65·50
	100·00	100·00

The ash consisted of phosphate of lime and alkaline sulphates, and chlorides.

I have made an attempt to introduce the residual coarse fibre as a raw material for paper manufacture, but consumers say that it is too weak and lacking in tenacity. For paper making the starch still remaining could be recovered by steeping in boiling water, and used for sizing the finished paper.

Owing to the fall in the value of sugar, the production of arrowroot in the West Indies has been extended rather beyond the demand. The wholesale price has consequently fallen to an almost unremunerative point. This low price, however, will permit it to be used for whatever purposes the commoner kinds of starch are now employed. In some respects it is superior to common starch, and one of my chief objects in writing this paper is to draw the attention of large users of starch to this comparatively new source of very fine starch. Arrowroot swells much more readily and with less heat than maize, rice, or wheat starch, and forms a stiffer jelly. It is, therefore, highly adaptable for sizing and laundry purposes. I think this property is attributable to the larger size of the granules of arrowroot starch which are among the largest of the starch granules, whereas the granules of wheat, maize, and rice starch are very small and will contain a greater proportion of starch cellulose and less granulose, the latter being the substance which swells when dissolved in hot water. Another use for which arrowroot starch is very suitable on account of its great purity and freedom from chemicals, is for the preparation of powder for the skin. Many of the powders sold are composed of very questionable ingredients: arrowroot well crushed and dried on a plate before the fire is both simple and safe.

It is as an article of food, however, that it has hitherto been mostly used, but the exorbitant retail price put on it (from 8d. to 2s. per lb.) has kept it out of general use. Of course being starch it cannot have the flesh-forming power of flour and other nitrogenous meals, but it is the purest, most digestible and palatable of the starches, and is devoid of the unpleasant taste or flavour observed in potato starch and in the so-called cornflour, and other starches extracted from the cereals by the caustic soda and fermentation processes.

Regarding adulteration, this is only done when the arrowroot is for sale at a high retail price for food. This is chiefly effected by such cheap starches as those from potato sago and tapioca. I have also found chalk and plaster of Paris in arrowroot, but this is very rare. The microscope affords the only reliable means of detecting admixtures of starch, and as this is only within the reach of very few, admixtures often go on with impunity. I need not here enter into a description of the characteristics of various starch granules, for they are described in many well-known books. I find, however, that many of the prints given and the descriptions are very erroneous, so that one should resort more to personal observations, using samples of the various starches for comparisons, the origins of which have been carefully ascertained and noted. When examining a sample of unknown starch, a small portion from the standards should be mounted and compared in order to make sure of the origin of the unknown sample. If a thin well-washed section of the root be examined by the microscope, the arrangement of the cells is seen to be very perfect and beautiful, resembling somewhat a section of the honeycomb. The cells are hexagonal and very transparent, and are filled with very uniform starch granules. The pith of the root contains very small and somewhat irregular cells, which are filled with exceedingly small starch granules; this is probably the source of the smaller granules seen in a sample of arrowroot starch. The fibres are arranged in concentric rings round the pith. They are somewhat strong in the fleshy part of the root, but weak at the joints, which break very easily.

Regarding the annual production of arrowroot, I have not been able to obtain many statistics. Bermuda raises only 500 to 700 kegs, so that very little of what is sold as Bermuda really comes from there. Natal produces 2000 to 3000 cases, and St. Vincent about 22,000 brls., 20,000 of which come to England, and most of the remainder is sent to America. The production of other countries is, I believe, very small.

ANALYSIS OF ARROWROOT STARCH.

	Per cent.	Per cent.

DISCUSSION.

Dr. J. Campbell Brown (Chairman) said that the Society was indebted to Mr. Macdonald for his able and interesting paper. He thought it formed a very good appendix to Dr. Archbold's paper. No doubt it was new to most of them that the name arrowroot was derived from the Indian name signifying "mealy root," and he thought this a much better derivation than "arrow" root, the root that yields arrow poison.

Before calling on Dr. Hurter to read his paper, the Chairman read a letter received by the Local Secretary from Messrs. Cross and Bevan, stating their inability to attend, and intimating that if Dr. Hurter's experiments did not, as they understood, agree in results with theirs, it was probably because the conditions of electrolysis were different in the two cases.

Dr. Hurter said that in justice to himself he must say that he himself invited Mr. Cross to be present at that meeting. He then read his paper on Hermite's Process.

ON HERMITE'S ELECTROLYTIC PROCESS FOR THE MANUFACTURE OF BLEACHING LIQUOR.

BY FERDINAND HURTER, PH.D.

Some years ago, when an electrolytic process for the manufacture of soda and chlorine from common salt was advertised as the "Tyne alkali process," I made a series of experiments on the electrolysis of common salt, which led me to the general conclusion that for the production of articles of low price electrolysis as a manufacturing operation was impracticable. Even for such an article as chlorate of soda, the electrolytic preparation of which presents no difficulty, I found the process too expensive, the efficiency of the current being extremely low. I was, therefore, greatly surprised to find, on reading Messrs. Cross and Bevan's paper on the Hermite process, that their results differed so far from mine as to lead them to entirely opposite conclusions, and to calculate a handsome profit on the electrolytic preparation of a substitute for so cheap an article as bleaching powder. I must, therefore, have been wrong in my conclusions, and I determined to make a few experiments myself, particularly as Messrs. Cross and Bevan obtained much more chlorine from a given current than could be calculated by Faraday's law, a result which was diametrically opposed to all my experience, for I had never been able to obtain as much as the theoretical quantity.

The Hermite process, as described in the English specification of patent No. 3957, 1886, consists in electrolysing solutions of the chlorides of the alkalis and alkaline earths between electrodes of platinum or carbon, as anodes and mercury, or amalgamated zinc plates as cathodes. The apparatus described consists of a tank, the bottom of which is covered by a layer of mercury at a distance above which the anode of platinum is placed horizontally. The anode is perforated to permit the free escape of gases. It is asserted that during the electrolysis of the chlorides the metal of the chloride amalgamates with the mercury, and that this is an essential feature of the process.

From Messrs. Cross and Bevan's paper we learn that the best results are obtained by the use of magnesium chloride of such concentration that one litre contains 25grms. of the anhydrous chloride. With such a solution Messrs. Cross and Bevan obtained in four successive periods the following amounts of chlorine :—

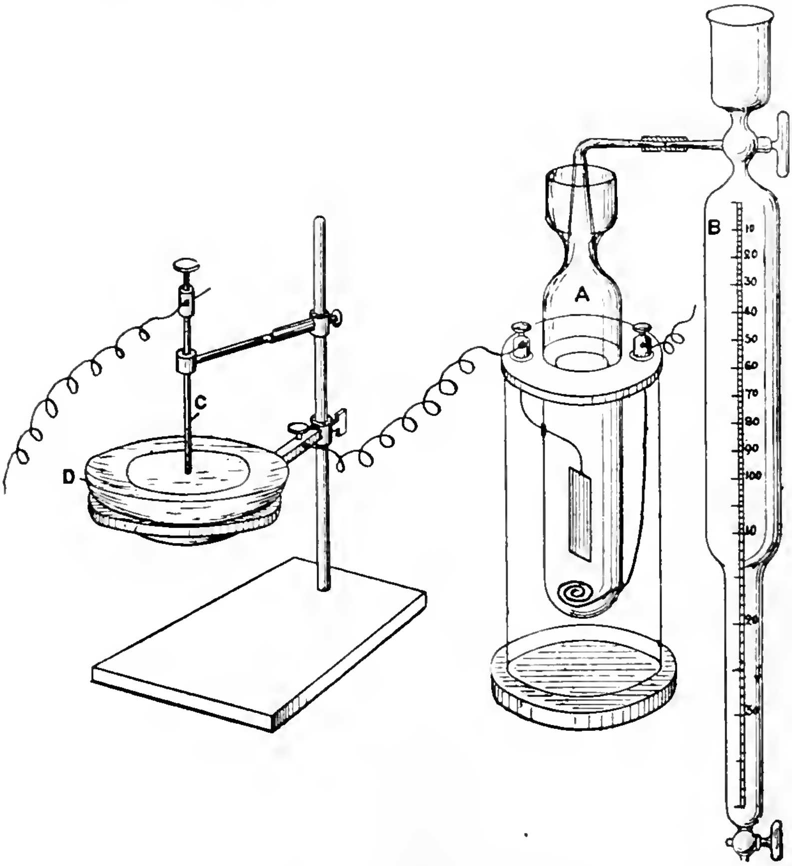
	Per Ampère Hour.	Or for 100 Cl theoretically possible.
1.	1·80grms.	134·3%
2.	1·12 ,,	83·5
3.	1·56 ,,	116·3
4.	1·40 ,,	104·4
Mean.	1·47grms.	109·4

The low result in the second period is said to be explained by the addition of lime, which in some way diminishes the yield.

Upon these marvellous results, Messrs. Cross and Bevan quite seriously base a calculation of costs to which I shall refer later on.

The first point which I had to investigate was, whether this high yield was a reality or an illusion

Clearly, if one ampère gives more chlorine than the electro-chemical equivalent, it must also yield more magnesium, or since that metal is not deposited in the metallic state, we must obtain more hydrogen gas. I, therefore, so arranged my experiments that I could measure and analyse the gas obtained during the electrolysis as well as the electrolysed liquid. The apparatus was very simple, the electrolytic cell A consisted of a glass cylinder in which were fused in at the bottom a platinum spiral, afterwards covered with mercury, and higher up a piece of platinum foil serving as anode. The cylinder was closed by a gas delivery tube ground into the neck. This delivery tube was connected to a Bunte's burette B, in which the gas could be measured and analysed. The current of a Bunsen battery, after passing the cell, was conducted through a copper voltameter, consisting of a copper plate C as anode, and a platinum dish D as cathode, containing pure copper sulphate solution three-fifths saturated as electrolyte; the current afterwards passed through a galvanometer. I will only trouble you with the details of one single experiment, as most of them were carried out in a similar manner.



Experiment No. 1.—A solution of magnesium chloride containing 8·70grms. of $MgCl_2$ per litre was electrolysed in two successive stages, for both of which the amount of copper deposited and the gases evolved were determined separately; but owing to the small amount of solution in the cell, this was only analysed after the second stage.

The gas obtained during the first stage amounted to 37·3cc., corrected for temperature and pressure, and consisted of—

Cl	1·50	per cent.
O	9·17	,,
H	89·03	,,

The copper deposited during this period amounted to 0·1035grm., which, taking 0·0003307 as the electrochemical equivalent of copper, corresponds to 313 coulombs (ampère-seconds) of electricity.

The amount of hydrogen in the gas corresponds to 37·3 × 0·8903cc. = 33·20cc., and as each cc. corresponds to 8·533 coulombs, the hydrogen only accounts for 283 coulombs. Similarly calculated, the oxygen is equivalent to 60·2 coulombs, and the chlorine evolved to 4·7 coulombs.

Consequently, for every 100 coulombs which were measured in the copper voltameter, only 90·4 [313 : 283 :: 100 : 90·4] evolved their equivalent of hydrogen, or 100—90·4 = 9·6 coulombs passed through the electrolytic cell without evolving hydrogen, and since when no hydrogen is evolved at the cathode, no chlorine or oxygen can be evolved at the anode with magnesium chloride solution as electrolyte, 9·6 per cent. of the current were ineffective for the production of chlorine. Another portion of the current—viz., 19·25 per cent. [313 : 60·2 :: 100]—produced oxygen at the anode instead of chlorine; this portion also was ineffective as regards production of chlorine, so that we have only 100—(9·6 + 19·25) = 71·15 per cent. of the current which really did produce chlorine.

I shall term the percentage of current which really yields chlorine, or oxygen compounds of chlorine, the efficiency of the current.

During the second stage of the electrolysis of this solution a gas was obtained consisting of 10·75 per cent. of oxygen and 89·25 per cent. hydrogen gas, and measuring 38·6cc. (reduced volume). The copper collected in the voltameter amounted to 0·1126grm., corresponding to 340 coulombs. A similar calculation to the previous one shows that in the second period, for every 100 coulombs of electricity,

13·5 per cent. did not evolve hydrogen;
20·8 „ evolved oxygen instead of Cl.

31·3 per cent. were ineffective for the production of chlorine, and only 65·6 per cent. produced chlorine.

The mean of both periods is—

11·5 per cent. produced no hydrogen.
20·02 „ „ oxygen.
68·48 „ „ chlorine.

The solution was now analysed.

The total chlorine was determined in the solution before electrolysing by means of silver nitrate.

The *available* chlorine, meaning thereby free chlorine and hypochlorites, all calculated to their equivalent of free chlorine, was determined by means of an acidulated solution of iodide of potassium, the iodine set free being titrated with sodium thiosulphate.

The total oxidising chlorine of the solution (including in this term free chlorine, hypochlorites, and chlorates, all calculated to their equivalent of free chlorine) was determined by boiling a portion of the solution with a standard solution of ferrous chloride and titrating with potassium bichromate, as the solutions must be made strongly acid with hydrochloric acid if the chlorates are to be thoroughly decomposed.

These methods of analyses were followed in all experiments, except where special points had to be settled.

The solution was thus found to contain—

Total chlorine	0·3578grm.
Available chlorine	0·0619 „
Total oxidising chlorine	0·1698 „

The electro-chemical equivalent of chlorine being 0·0003727, the available chlorine corresponds to 166 coulombs, and the total chlorine to 456 coulombs.

As during the two periods 313 + 340 = 653 coulombs had passed through the voltameter, the efficiency of the current as calculated from the analysis of the solution is—

For available chlorine	25·1 per cent.
„ total oxidising chlorine	69·7 „

whilst the efficiency from gas analysis is for total oxidising chlorine 68·48 per cent.

This approximation shows that gas analysis alone is sufficient to settle the efficiency of the current.

Before giving you the results of further experiments, it will be convenient to explain shortly the reactions which go on in the cell. I am afraid I shall trouble you with rather too elementary an explanation, but as the subject has been unnecessarily mystified in Messrs. Cross and Bevan's paper, I wish to be exceedingly careful to clear the mysteries away.

The primary result of the electrolysis of most chlorides is the separation of the atoms, the metal appearing at the cathode, the chlorine at the anode. When the metal is capable of decomposing water, the metal is separated as hydrate, and its equivalent of hydrogen is evolved at the cathode. Magnesium chloride forms no exception to this rule.

The first products of the electrolysis of magnesium chloride are chlorine gas at the anode, hydrogen and magnesia hydrate at the cathode. When the solution of magnesium chloride is alkaline the chlorine does not escape, when the solution is neutral some chlorine does escape, as the first gas analysis shows; but when chlorine and magnesia have been produced in sufficient quantity and diffused through the solution, they react upon each other in the well-known manner according to the equation: $2MgH_2O_2 + Cl_4 = MgCl_2O_2 + MgCl_2 + 2H_2O$, producing magnesium hypochlorite and chloride.

The solution then contains two salts, magnesium chloride and hypochlorite, both of which are electrolytes.

The current of electricity has now the choice of travelling by two conductors instead of only one, and according to the quantity of each salt present divides itself in a certain ratio, one portion continuing to decompose magnesium chloride, another portion decomposing the hypochlorite.

When oxygen salts are electrolysed, the usual result is the appearance of the metal at the cathode; or when the metal decomposes water, hydrogen is evolved and the hydrate of the metal formed at the cathode, while the acid separates at the anode together with the oxygen belonging to the base. Thus the electrolysis of magnesium hypochlorite produces hydrogen and magnesia at the cathode, while oxygen and hypochlorous acid should be found at the anode.

These are the primary reactions which account for the hydrogen and oxygen found in the gases, but which do not account for that part of the current which did not evolve hydrogen, nor explain why the whole of the chlorine produced is not available chlorine.

It is well known, when the solution of an oxidising agent is electrolysed, that as a secondary reaction the nascent hydrogen at the cathode reduces partially the oxidising agent. This is exactly what happens in this case; part of the hypochlorite is reduced again to chloride. The hydrogen being oxidised to water does not appear in the gaseous products. This is the explanation of the hydrogen which is missing.

While this secondary reaction is proceeding at the cathode, there is another secondary process going on at the anode. It is a well-known fact that hypochlorous acid very readily changes into chloric acid, and it is a peculiarity of the electrolysis of the hypochlorites that, instead of hypochlorous acid, chloric acid is formed at the anode. By what steps this happens is of little consequence; I will represent the results of the electrolysis of the hypochlorite by equations as follows:—

$$3MgCl_2O_2 + 9H_2O = \underbrace{3MgH_2O_2 + H_6}_{\text{Cathode.}} + \underbrace{6HClO + O_3}_{\text{Anode.}}$$

$$6HClO = 2HClO_3 + 4HCl.$$

Of course all these acids do not remain free, but soon combine again with magnesia. What I wish to point out by these equations is this: For every two molecules of chloric acid so formed there are three atoms of oxygen evolved. But whereas the six molecules of hypochlorous acid would count as available chlorine, and would be equivalent to 12 atoms of free chlorine, the two molecules of chloric acid into which they are transformed do not count as available chlorine, and consequently for every three atoms of oxygen evolved the available chlorine in the solution is reduced by an amount equivalent to 12 atoms of free Cl. If we translate this result into current efficiency, we have to remember that each atom of oxygen corresponds to two coulombs, and each atom of chlorine to one coulomb.

Consequently, we may say that for every six coulombs of the current which produce oxygen, the available chlorine which requires 12 coulombs for its production vanishes, or for every coulomb which produces oxygen the available chlorine corresponding to two coulombs vanishes.

If we review the results of the experiment in the light of this explanation, we can say that as the amount of oxygen evolved corresponds, on the average, to 20·02 per cent. of the current, that 20·02 per cent. of the current electrolysed $MgCl_2O_2$, producing oxygen and chlorate at the anode, and hydrogen at the cathode. In consequence of the reduction of hypochlorite at the cathode, 11·5 per cent. of the hydrogen due to the current was not evolved; and in consequence of the conversion of hypochlorite into chlorate at the anode, 2 × 20·02 per cent. of the available chlorine were rendered unavailable, so that of the chlorine which 79·98 per cent. of current yielded, 11·6 were reduced again at the cathode, and 40·04 changed into chlorate, leaving only 28·34 per cent. of the current useful for available chlorine. From the analysis of the solution, the efficiency for available chlorine was found to be 25·4 per cent. When we remember that magnesium hypochlorite readily changes into chlorate under ordinary conditions, the difference between the results is not important, and the experiment is a proof of the explanation given.

Experiment No. 2.—Magnesium chloride solution, containing 24·15grms. $MgCl_2$ per litre. Gas collected in two portions, and copper in voltameter weighed for each.

	1st Stage.	2nd Stage.
Total volume	37·25cc.	45·70cc.
Hydrogen	95·57	95·0
Oxygen	4·43	5·0
Cu collected	0·1189grm.	0·1459grm.

From these results we calculate that 91·16 per cent. of the current electrolysed magnesium chloride, yielding chlorine at anode, and hydrogen at cathode, and that 8·84 per cent. of the current electrolysed magnesium hypochlorite, yielding chlorate and oxygen at anode; 16·10 of the hydrogen reduced hypochlorite at cathode, and 17·68 of available chlorine became unavailable, owing to transformation into chlorate. Hence, from gas analysis, the current efficiency was: 75·06 per cent. for total oxidising chlorine, and 57·38 per cent. for available chlorine. The analysis of the solution gave—

Available chlorine	0·1171grm.
Total oxidised chlorine	0·2316 ,,

From which the efficiencies are calculated to be 77·66 per cent. for total oxidising chlorine, and 49·3 per cent. for available chlorine, much less than from the gas analysis, owing to spontaneous conversion of hypochlorite into chlorate.

Experiment No. 3.—Magnesium chloride solution, containing 68·6grms. $MgCl_2$ per litre.

Total volume of gas	84·1cc.
Containing 97·5% hydrogen.	
2·5 oxygen.	
Copper collected	0·2728grm.
Cl as available in solution	0·2116 ,,
Cl as total oxidising chlorine	0·2397 ,,

From these data the current efficiency is from gas analysis: 80·12 and 71·42; from the solution, 77·94 and 68·84 respectively, for total and available chlorine.

Experiment No. 4.—Solution containing 33·39grms. $MgCl_2$ per litre.

Gas obtained	158·1cc.
Containing Cl	1·05
Oxygen	3·95
Hydrogen	95·00
Copper collected amounts to	0·5275grm.
Available chlorine found	0·3550 ,,
Total oxidising chlorine	0·4135 ,,

From which data the efficiency is calculated to be, from gas analysis, 73·63 and 60·26 per cent.; from the analysis of the solution 69·58 and 59·7 respectively, for total and available chlorine.

I have tabulated these results so that the resemblance in the results from the analysis of gas and liquid may be perceived. I have also added the percentage of chlorine in the solution, which was converted by the current.

RESULTS OF EXPERIMENTS I.–IV.

Experiment No—		1	2	3	4
Efficiency of Current per Gas Analysis	Total Oxid. Cl	68·4	75·0	80·1	73·6
	Avail. Chlorine	28·3	57·4	71·4	60·2
Efficiency of Current per Analysis of Solution	Total Oxid. Cl	69·7	77·5	77·9	69·1
	Avail. Chlorine	25·4	49·2	68·7	59·8
Magnesium Chloride in grms. per litre		8·7	24·1	68·6	33·4
% of Chlorine converted	into total Oxid. Cl	47·5	21·0	7·9	8·7
	,, avail. Chlorine	17·1	13·3	7·0	7·5

It will be seen that in this series of experiments the results of the gas analyses tolerably well agree with the results of the analysis of the solution. But this is only so when the electrolysis has not advanced very far, as it has not done in any one of the above experiments. The method of stating the total oxidising chlorine is apt to give a very wrong impression of the composition of the solution. Thus, in Experiment No. 1 it is stated that the oxidising power of the solution was equivalent to 47·5 per cent. of the total chlorine in the solution, giving one at first sight the very erroneous impression that nearly the half of the magnesium chloride had been decomposed. In reality that very solution consisted still chiefly of magnesium chloride, for it contained, for 100 molecules of magnesium chloride, in round numbers—

$MgCl_2$	100 molecules.
$MgCl_2O_2$	10 ,,
$MgCl_2O_6$	6 ,,
$MgCl_2O_8$	(?)

When the electrolysis is pushed still further, the analysis of the gas no longer permits to form so approximate an idea of what is proceeding in the electrolytic cell: the analysis of the solution only can be relied upon, as is shown by the following experiment carried out in a different apparatus:—

Experiment No. 5.—Solution containing 25·9grms. $MgCl_2$ per litre.

Gas obtained	1380cc. corrected vol.
Containing H, 87·5%	
,, O, 12·5	
Copper collected in voltameter	4·1687grms.

The solution was found to contain:—

Chlorine equivalent to total oxidising power	2·308grms.
Available chlorine	0·630 ,,

From these results the following efficiency for the current, calculated in the same way as explained, are obtained:—From gas analysis: for total oxidising chlorine, 58·0 per cent.; for available chlorine, 11·4 per cent. From the analysis of the solution, 49·1 per cent. for total oxidising chlorine, and 13·2 per cent. for available chlorine.

In this experiment, for every 100 coulombs passed through the voltameter, 18·75 had passed without producing H in the electrolytic cell, and 23·3 had produced oxygen at the anode instead of chlorine. The total oxidising chlorine amounted to 78·2 per cent. on the total chlorine contained in solution.

From this experiment, and various differences in the others, it is evident that another reaction was going on in the cell, which had not been taken into account. In order to discover whether it was a reaction due to hypochlorites, or whether it was due to the chlorate formed, I electrolysed a solution of bleaching powder, nearly free from chlorate, which the hypochlorite solution obtained by electrolysis never is; and I also electrolysed a solution of potassium chlorate. The following are the results:—

Experiment No. 6.—Solution of bleaching powder, containing 18·193grms. available chlorine and 19·965 grms. total oxidising chlorine per litre, was electrolysed.

The gas obtained amounted to 36·5cc. corrected volume, and contained—

Hydrogen.. 41·32 ,, corresponding to 129 coulombs.
Oxygen .... 58·68 ,, 366 ,,

The copper deposited in voltameter amounted to 0·3350grm. = 1013 coulombs.

After electrolysis, it was found that the solution had lost available chlorine, corresponding to 0·390 grms. = 1046 coulombs, or electro-chemical equivalents.

These results must be interpreted as follows: Of the 1013 coulombs measured in the voltameter—

366 electrolysed calcium hypochlorite.
647 electrolysed calcium chloride.

Since only 129 coulombs of the electricity produced hydrogen, 884 coulombs have reduced hypochlorite to chloride. We have therefore—

Gain of available chlorine by electrolysis of calcium chloride	647	electro-chem.	equivalent.
Loss of available chlorine due to reduction at cathode	884	,,	,,
Due to conversion to chlorate, 2×366	732	,,	,,
	1616		
	647		
Balance of loss	969	,,	,,

According to analysis of solution, the reduction in available chlorine was 1046 electro-chemical equivalents.

Experiment No. 7.—Bleaching powder solution containing 19·30grms. available Cl per litre was electrolysed.

Gas obtained = 36·5cc. corrected vol.
Hydrogen, 36·3 per cent., corresp. to 113·5 coulombs.
Oxygen 63·7 ,, ,, ,, 397·0 ,,
Copper deposited in voltameter, 0·3170grm. = 959 coulombs.

Analysis of solution showed a decrease in available chlorine of 0·382grm., corresponding to 1024 coulombs (electro-chemical equivalents). We have, therefore, 959—113=846 coulombs passing through the cell, which reduce hypochlorite at cathode, and 397 coulombs converting hypochlorite into chlorate, equivalent to a loss of 2 × 397 = 794 equivalents available chlorine. The total loss of available Cl is therefore 846 + 794 = 1640 equivalents. But by electrolysis of 959—397 = 562 equivalents of calcium chloride we gained available chlorine, so that the real loss amounted to 1640—562 = 1078 equivalents, whereas the analysis of the solution shows the loss to be 1024 equivalents.

These two experiments show very clearly that as far as the electrolysis of chlorides and hypochlorites are concerned, the explanation given is absolutely correct, that the formation of chlorate exactly corresponds to the oxygen found in the gas, and as calcium hypochlorite does not under ordinary circumstances change into chlorate, the change must be due to the current; and that as the solution becomes richer in hypochlorites, the hydrogen evolved decreases more and more. Whereas in the experiments in which there is no available chlorine in the solution at the beginning, the current evolves about 90 per cent. of the theoretical quantity of hydrogen, in these latter experiments, where the solution contained 19grms. of available chlorine per litre, the hydrogen evolved by the current is only 13 to 15 per cent. of the theoretical quantity, and consequently electrolysis can by no possibility yield a solution in which the proportion of chloride to hypochlorite equals that of a solution of bleaching powder, since under these circumstances the current destroys more hypochlorite than it produces.

In both these experiments with bleaching powder solution there was, in addition to the loss of available chlorine, a small loss of total oxidising chlorine. I have taken no notice of it, in order not to complicate matters, as the following experiments will clearly show from what cause the discrepancies between gas analysis and analysis of solutions arise:—

Experiment No. 8.—A solution of potassium chlorate was electrolysed. The solution contained 46·0grms. of potassium chlorate per litre. During a first trial 46·4cc. of gas were collected, consisting of—

36·6 per cent. oxygen corresp. to 290 coulombs.
63·36 ,, hydrogen ,, 251 ,,

During the same time 0·1170grm. copper were deposited in the voltameter. Neither of the gases corresponded to the theoretical quantity which ought to be obtained if the electrolysis proceeds according to the equation—

$$2KClO_3 + 3H_2O = \underbrace{2KHO + H_2}_{\text{Cathode.}} + \underbrace{2HClO_3 + O}_{\text{Anode.}}$$

On interrupting the current it was found that the mercury cathode still continued to evolve gas, a phenomenon which had not in any previous experiments manifested itself. It was evident that a potassium amalgam had formed to some extent, which required time for its decomposition.

Accordingly a new experiment was made.

Experiment No. 9.—The electrolysis of a similar solution was conducted in two stages.

Owing to too small a gas burette, a small quantity of the hydrogen evolved after opening the circuit was again lost in the first period.

1st Period: Gas obtained with closed circuit, 38·8cc., increasing after opening the circuit to 50·6cc.; corrected volume = 47·5cc. Gas consisted of—

Oxygen 36·17 per cent., corresp. to 294 coulombs.
Hydrogen. 63·83 ,, ,, ,, 259 ,,
Copper deposited in voltameter, 0·1335grm. = 403 coulombs.

2nd Period: Gas obtained, 27·5cc., increasing after opening the circuit to 46·1cc., or 44·1cc. corrected volume. Gas contained—

Oxygen 26·3 per cent., corresp. to 198 coulombs.
Hydrogen. 73·7 ,, ,, ,, 278 ,,

In this case the evolution of gas had entirely ceased.

The copper deposited during this period was 0·0920grm. = 278 coulombs.

The first point I wish to draw your attention to is that in this latter period, where there was no failure, the hydrogen evolved corresponded exactly to the copper deposited, so that no reduction of chlorate takes place at the cathode. But the oxygen evolved at the anode is for both periods together 492 electro-chemical equivalents, whilst 681 ought to have been obtained according to the amount of copper deposited; the difference, 189, was absorbed in the solution.

Analysis of the solution showed that the total oxidising chlorine had decreased by an amount corresponding to 0·1037grm. of potassium chlorate. That this decrease was not due to any reduction of chlorate to lower oxides of chlorine or to chloride was proved by testing the solution for available chlorine with iodide of potassium which was not discoloured, and for chloride by nitrate of silver which gave no precipitate.

The chlorate was simply oxidised to perchlorate, which, as is well known, will not yield its oxygen to an acid boiling solution of ferrous chloride.

According to the equation $KClO_3 + O = KClO_4$, we see that for every atom of oxygen used for oxidation one molecule of potassium chlorate vanishes. Consequently, if the 0·1037grm. of potassium chlorate were oxidised to perchlorate, they required 0·0135 grm. of oxygen, which correspond to 161 electro-chemical equivalents. By the gas analysis 189 electro-chemical equivalents of oxygen had been used for oxidation. The slight difference is due partly to errors in analysis, partly to the fact that a portion of the oxygen in the gas was in the allotropic form ozone, and was not, therefore, correctly measured, a difficulty frequently experienced in electrolytic work.

Experiment No. 10.—Exactly similar to the previous one; carried out on a much larger scale. Owing to collecting the gases by displacing water in an aspirator, a correction must be allowed in the measurement of the gases. The electrolysis was divided into three stages, and the liquid analysed after the third stage only.

	I.	II.	III.
Total gas collected	2016cc.	1972cc.	1937cc.
Hydrogen..............	69·33	73·25	70·26
Oxygen	30·67	26·75	29·74
Copper collected	3·9976	4·2005	3·8262

Total copper corresponds to 36360 coulombs.
" hydrogen " " 35857 "
" oxygen " " 29380 "

This latter figure needs increasing by three per cent. owing to absorption in water of aspirator, which brings it to 30,271.

The solution was found to have lost 3·672grm. of chlorate, requiring 0·4780grm. of oxygen for oxidation to perchlorate. This amount of oxygen corresponds to 5691 electro-chemical equivalents, whereas in the gas are missing 6089. The discrepancy is due to the same cause, the formation of ozone. The perchlorate formed crystallised out, and was examined.

The important point in these experiments on the electrolysis of chlorates is, that the current very easily electrolyses them, producing its exact equivalent of hydrogen at the cathode (except at first), and nearly five-sixths of an equivalent of oxygen at the anode, the rest of the oxygen being taken up by the chlorate to form perchlorate.

It is for this reason that calculations from gas analyses, and from the analyses of the solutions, do not agree perfectly, particularly when the solution contains any appreciable amount of chlorate, because the total oxidising chlorine is reduced by 6 equivalents for every equivalent of chlorate changed into perchlorate by the current, and the gases are enriched by a certain amount of oxygen, to which there is no corresponding transformation of hypochlorite into chlorate.

What we have learnt, so far, may be summed up in a very few words. 1. There is no failure of Faraday's law in the electrolysis of magnesium chloride. 2. Owing to the presence, after some little time, of two or three other salts besides the original chloride, part of the current electrolyses them, and thus is wasted, and not only wasted, but actually undoes continuously a portion of the work which another portion of the current is doing.

If you bear in mind that in the experiments with the bleaching powder solution the result was a loss of available chlorine of nearly 35 per cent., you will the more readily see that there is a limit to the relative amount of chloride and hypochlorite in solution, beyond which electrolysis cannot go, and beyond which the current is absolutely wasted, if it is intended to prepare bleaching solutions.

The following experiment was made in a tank holding two litres, between anodes of platinum and cathodes of amalgamated zinc, the current being measured as hitherto by a copper voltameter.

The results are tabulated, and will be readily understood. The amount of solution in the tank was approximately 2 litres. The electrolysis was carried out in five periods. (See table below.)

EXPERIMENT No. 11.

(SOLUTION CONTAINED 26·6GRMS. $MgCl_2$ PER LITRE.)

PERIOD.	Total Chlorine Produced.		Copper Collected.		Cl. equivalent to Cu.	Current Efficiency.		On Total Chlorine in Solution.	
	Avail.	Total.	Each Period.	Total.		Avail.	Total.	% Available.	% Total Oxide.
	Grm.	Grm.	Grm.	Grm.	Grm.	%	%		
1	3·72	1·42	5·75	5·75	6·44	57·7	68·6	9·35	11·10
2	6 38	13·91	20·38	26·13	29·26	21·8	47·5	15·4	34·2
3	7·84	17·11	6·85	32·98	36·93	21·2	46·3	19·36	42 8
4	8·25	24·66	17·43	50·11	56·44	14·6	43·6	20·51	64·6
5	8·35	27·16	5·68	56·09	62·82	13 3	43·7	20·8	73·4

It will be evident from this table that the limit of the available chlorine worth having had been reached with a current efficiency of 22 per cent. only, after the 2nd or 3rd period; from that period the current produced an increase in the hypochlorites or available chlorine at very great cost. In order to show the intimate connection between the current efficiency and the limit to which electrolysis of the solution is pushed, I append the subjoined tables, which include all the experiments with magnesium chloride detailed in this paper, or all the experiments I have made in which the current was measured by means of the copper voltameter. I also append diagram to show the difference of the results obtained by Messrs. Cross and Bevan and myself, and their relation to the theoretical amount:—

A.—SMALL SCALE EXPERIMENTS.

(AMOUNT OF SOLUTION USED, 60—150CC. MERCURY AS CATHODE, PLATINUM AS ANODE.)

No. of Experiment—	3	4	2	1	5
Available Chlorine %	7·0	7·5	13·3	17·4	20·4
Total Oxidising Chlorine	7·9	8·7	21·0	47·5	78·2
Current Efficiency for available Chlorine %.	68·7	59·8	49·2	25·4	13·2

B.—LARGER SCALE EXPERIMENTS.

(AMOUNT OF SOLUTION USED, 2 LITRES. AMALGAMATED ZINC AS CATHODE. PLATINUM AS ANODE.)

Period of Experiment No. 11.	1	2	3	4	5
Available Chlorine %	9·3	15·4	19·3	20·5	20·8
Total Oxidising Chlorine %	11·1	34·2	42·8	61·6	73·4
Current Efficiency for available Chlorine %	57·7	21·8	21·2	11·6	13·3

I will not give the details of the following few experiments, made with a view to ascertain the influence of carbon anodes. The current was measured by the copper voltameter:—

C.—EXPERIMENTS WITH CARBON ANODES.

(AMOUNT OF SOLUTION, 150—250CC.)

	Cathode. Amalgamated Zinc.			Cathode. Mercury.
% Total Oxidising Cl......	47·2%	16·6%	.....	18·3%
Current Efficiency	1·07	13·4	......	12·7

D.—EXPERIMENTS WITH SMALL DYNAMO MACHINE.

(CURRENT MEASURED BY GALVANOMETER.)

Carbon Anodes.	Amalgam. Zinc Cathodes.		
Current Efficiency for available Cl	39·7%	......	11·3%
Total Oxidising Cl	1·07	......	3·78

I have not had time to find experimentally a satisfactory explanation why the results with carbon anodes were so much worse than those with platinum anodes. The carbon anode is rapidly acted upon, and disintegrated; the gases evolved contain carbonic acid to the amount of 3 per cent. But what are the chief products of the oxidation of the carbon, I have not ascertained. The solutions are coloured yellow when electrolysed by carbon anodes.

I have made a great many experiments with current densities, varying from ½ to 40 ampères per square foot, with vertical and horizontal electrodes, with various distances between them. There is only one result to be got, and that is a miserable current efficiency whenever you wish to reach a solution which shall equal a solution of about 1° Tw. of bleaching powder—*i.e.*, contain 5grms. available chlorine per litre.

This is as much of experimental evidence as I think is necessary to give a pretty correct idea of the commercial value of this process.

Messrs. Cross and Bevan have presented us with a calculation of the cost of producing bleaching solution by the Hermite process equivalent to one ton of bleaching powder.

They take as basis for their calculations—

(1.) One ampère-hour yields 1·47grms. of available chlorine, which, in my way of expressing results, is a current efficiency of 109·7 per cent.

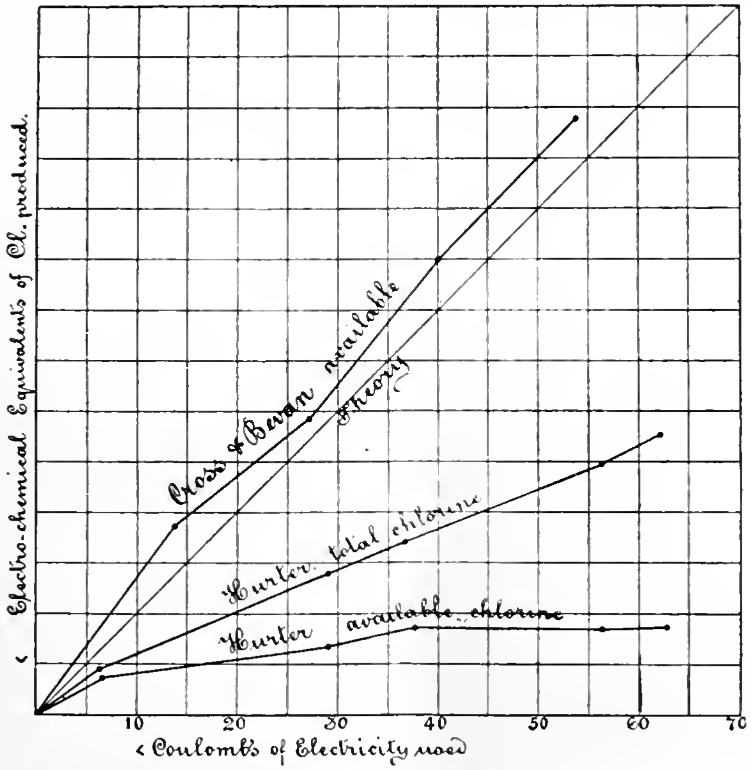
(2.) They assume that the available chlorine produced has greater bleaching efficiency than the same amount of available chlorine in bleaching powder in the proportion 3 : 5.*

(3.) They assume that the waste of magnesium chloride is inappreciable.

(4.) That an installation including dynamo for a current of 1000 ampères and 5 volts, steam engine, leads, and tanks, comprising platinum anodes, will cost £350; every such unit giving the equivalent of ⅙ ton of bleaching powder in 24 hours, or 1 ton per week.

They thus arrive at the result that the equivalent of one ton of bleaching powder costs £2 10s.

I will discuss these points one by one.



(1.) We will accept, for the moment, the basis, but

---

* These two statements together mean that 1000 ampères decomposing $MgCl_2$ will give chlorine compounds of such efficiency as would equal free chlorine gas produced by 1800 ampères.

examine to what extent we should have to push the electrolysis in order to produce a bleaching solution containing, say, 5grms. of available chlorine, which is as much as a solution of bleaching powder of about 1° Tw. would contain. Since a 2½ per cent. solution of chloride of magnesium contains, in round numbers, 20grms. of chlorine per litre, we should have to carry on the electrolysis until 25 per cent. of the chlorine had become available chlorine. In none of my experiments with a 2½ per cent. solution of magnesium chloride was this result obtained, the highest being 21·8 with a current efficiency of 13·3 per cent.; and if we are satisfied with a bleach solution equivalent to a solution of bleaching powder of about ½° Tw., we may obtain it with a current efficiency of 20 per cent.

The explanation which Messrs. Cross and Bevan give for their current efficiency of 110 per cent. is that, owing to the incomplete separation of the ions, Faraday's law requires a different interpretation, and is inapplicable to the electrolysis of magnesium chloride. Professor Armstrong, in the discussion on their paper, said something must be wrong. I have clearly shown what is wrong. I have not only shown that this high efficiency is an illusion, but I have clearly shown what every single ampère has done in passing through the cell. I must, therefore, accept my own current efficiency as the only reliable one, though Messrs. Cross and Bevan assert that their measurements were accurate within 1 per cent. My experiments show that the reactions in the cell are totally incompatible with their results; that the reasons for the low current efficiencies are not to be found in mere physical or mechanical conditions, but are due to the fact which they themselves admit—the extensive complications with which this electrolysis is attended. There are certainly no indications in the inventor's specification of means to prevent the current electrolysing the very products of the electrolysis which he wishes to produce.

Thus, leaving as they stand the marvellously cheap plant, the cheap horse-power, and the extraordinary bleaching properties of the electrolysed solution, the cost of one ton of the hypothetical bleach rises in the proportion of 20:109, from £2 10s. to something between £13 15s. and £25, according as we are satisfied with a solution corresponding to a bleach solution of about ½° Tw. or 1° Tw.

(2.) The assumption of Messrs. Cross and Bevan that the electrolytic bleach liquor has greater bleaching power than a solution of ordinary bleaching powder rests probably on as insecure a basis as their statement and explanation of the high yield of chlorine. They explain that the bleaching compounds are of high tension. They assert that the solution contains hydrogen peroxide and higher oxides of chlorine. Some of the bleaching compounds were soluble in ether, and evaporated with the ether into thin air.

It is surprising to hear that the solution contains peroxide of hydrogen. Hydrogen peroxide is as deadly an enemy to hypochlorites as the Hermite process is, in Messrs. Cross and Bevan's opinion, to the present chlorine industry. The very fact that these two compounds do not exist in one solution has been made use of by Professor Lunge for a new method of estimating the chlorine in bleaching powder.* There is no chance whatever for peroxide of hydrogen to exist beside the hypochlorites. As to the higher oxides of chlorine, I have mentioned those I found. I searched for the missing one—the chlorite—but failed to prove its presence. Chlorates and perchlorates are useless to the bleacher. I am driven to the conclusion that the whole difference, if there really is one, is due to the difference in speed with which magnesium hypochlorite and calcium hypochlorite do their work, a difference which has already been noticed by other authors. Perhaps the solution contains a little free hypochlorous acid.

If bleaching is oxidation, the assumption that the magnesium hypochlorite will do 166 per cent. of the work which the equivalent amount of calcium hypochlorite would do, is as devoid of foundation as the assertion that Faraday's law did not directly apply to the electrolysis of magnesium chloride.

I for one must dismiss this higher efficiency as a basis of calculation, and I must consequently raise the price of the "hypothetical bleach" once more in the proportion of 3 : 5, which brings the price up to £22 8s. or £42, according to the strength of the solution required.

(3.) In estimating the horse-power necessary to do the work, Messrs. Cross and Bevan speak in the same sentence of using 5 volts, and of obtaining 600 Watts from 1 horse-power. If they really mean to employ a machine giving only 5 volts, they will find themselves greatly disappointed; the horse-power will yield more, nearly 400 Watts instead of 600, which will make another considerable difference in the prices calculated. And they take no notice of the resistance of the circuit, which might make very serious differences also.

Messrs. Cross and Bevan wind up by saying that the chloride of magnesium is not wasted. It is proposed to circulate the liquid between the electrolytic tank and the bleaching tank. That is very beautiful in theory, but my experiments show that it cannot work for any length of time. There would gradually accumulate chlorate and perchlorate in the solution, and the efficiency of the current would so deteriorate that I believe it will pay better to throw the solution away after using it once or twice.

That the current will electrolyse chlorates and hypochlorites as easily as the chlorides may appear strange, since it is known from Professor Kohlrausch's researches that chlorates do not conduct quite as well as chlorides, the specific conductivity of magnesium chloride being 71, that of chlorate 57. But it must not be forgotten that the final result of the electrolysis of an oxygen salt is hydrogen and oxygen evolved from liquid water, the corresponding electromotive force being 1·45 volts, while the result of the electrolysis of a chloride yields chlorine and hydrogen, the electro-motive force being 1·66 volts.

Thus, the one salt, the chloride, would require a little greater difference of potential between the electrodes than the oxygen salts.

Be that as it may, the fact is the current divides itself among the various salts, as is well known in other cases, and any accumulation of chlorates and perchlorates would mean a serious loss of efficiency. But if ⅓ of the solution has to be thrown away when only ¼ is made useful, this means an expense for chloride of magnesium, at present prices, of £2 10s. per ton of bleach produced.

We are told that the proprietors of the patent-right are fitting up a research laboratory. Let us hope they will have no cause to regret having acquired the patent-right first and fitted the laboratory last.

DISCUSSION.

Dr. Campbell Brown said he must congratulate the meeting on having the privilege of hearing a most admirable paper, which was characterised, as Dr. Hurter's papers usually were, by profound knowledge and skill, and by a most elaborate and persevering pursuit of truth through a long series of experimental observations recorded in a most precise

---

* This Journal, 1886, 391.

manner. He supposed that every one who had endeavoured to decompose the chlorides of alkalis or alkaline earths had been puzzled by the apparently unaccountable proportions of hydrogen, oxygen and chlorine which were obtained. Some of them no doubt had come to the conclusion, without making quantitative determinations, that electrolysis was not satisfactory either for the production of chlorine or hypochlorite, but no one, he thought, had hitherto made quantitative experiments. Dr. Hurter had shown what really took place when the current passed through magnesium chloride, and the conclusions which he had made out were perfectly clear, and in accordance not only with Faraday's law, but with the fact, previously known, that the higher oxygen compounds of chlorine are produced by the electrolysis of chloride. Dr. Hurter certainly had advanced their knowledge of the subject very materially, and the manner in which he had done his work and placed it before them was beyond all praise. One could not avoid contrasting the clearness and precision of Dr. Hurter's paper with the absence of those qualities in the paper printed in the March number of the Journal.

Dr. Kohn remarked that the deficiency of hydrogen certainly showed that a secondary reaction had taken place with the formation of hypochlorite as shown, and asked if it might not be possible that the hypochlorous anhydride formed by the decomposition of the hypochlorite would combine with the hydrochloric acid, forming water and free chlorine. The chlorine would then act on the magnesium liberated and afterwards converted into magnesium hydrate, to form magnesium chloride, and thus account for the large percentage of this substance found at the end of the process. The cause of the deficiency of hydrogen would also be to some extent explained. As to the electrolysis of potassium chlorate, whereby oxidation to perchlorate took place, it appeared that if magnesium chlorate were formed to any extent, the deficiency of hydrogen would be to some extent made good.

Dr. Hurter, replying to the last speaker, said he presumed what was meant was that the deficiency of hydrogen could be accounted for by some hydrogen disappearing at the anode, owing to the oxidation of chlorate to perchlorate, and that there would be a deficiency of hydrogen at the cathode? That was not possible. The oxidation took place always at the anode, and when the electrolysis of chlorate proceeded they found the exact equivalent to the current of hydrogen in the gas. There was no hydrogen missing whatever. The gas which was missing in that case was the oxygen, and when they analysed the solution they found that the oxygen missing in the gas was retained in the form of perchlorate. That was the whole of the reaction that went on in the case of chlorate. In the case of hypochlorite, he understood Dr. Kohn to say that the missing hydrogen might be accounted for by the decomposition of the hypochlorite? He found that he had on the one side oxygen and chloric acid, and on the other side he ought to have its equivalent of hydrogen. With nascent hydrogen gas at the cathode, they might consider the cathode a sphere of reducing action, and a part of the work of the current consisted in reducing hypochlorite back into chloride, and he thought that the tolerably close correspondence between the results calculated from the gas analysis and on the strength of that explanation which forms the basis of the calculation, and those results calculated from the solution, showed that the explanation could not be very far wrong; and when they came to compare this statement with any number of reactions which are known to happen in the electrolytic cells—such, for instance, as the reduction of ferric chloride to ferrous chloride, the reduction of nitric acid, the reduction of chromic acid—they would find nothing strange in the fact that this very powerful oxidising agent, hypochlorite, should be reduced also. There was absolutely nothing new in his paper, as there was not much in Hermite's process. Two Russian chemists had published a book on electric bleaching ("Le Blanchiment Electrique," A Lidoff and W. Tichomiroff; Moscow, 1883), in which they showed that the result of the electrolysis was free chlorine, hypochlorites and chlorates. The circulating principle adopted by Hermite was described in *Génie Civil*, 1883, vol. iii. p. 367. There is very little new in Hermite's patent, except perhaps the fact that Hermite uses mercury as a cathode, and he did not think that was worth very much. The mercury very soon wore off the zinc plates, and there were other things just as good as pure mercury. The reactions he had explained were certainly true, and none of them new; and the only new thing, perhaps, was that he had shown the quantitative relation of the various products. It was very easy for any chemist to see that the more concentrated the solution becomes with hypochlorous acid, the more chlorate will be produced at the anode, and the more hydrogen will be oxidised at the cathode. Where the solution contains to begin with only pure magnesium chloride, there would be fully 100 hydrogen, and there would be fully 100 chlorine for every 100 coulombs, but as soon as the molecules of hypochlorites and chlorates increase in number, part of the current electrolyses them, and they could no longer expect to get 100 per cent. of chlorine from the current. Of Faraday's law there was not failure, but it is impossible to get chlorine from that part of the current which does other work than that of electrolysing magnesium chloride.

Mr. A. Watt asked, if the solution got warmed in passing a current through it, would it facilitate the formation of chlorates?

Dr. Hurter, in reply, said it would very materially. The chlorates were formed from the very beginning, and they were formed in tanks of 30 litres just as much as they were in a small cell holding 50cc.

DISCUSSION ON MR. WESTMORELAND'S PAPER, "DETERMINATION OF SULPHUR IN PYRITES" (February Journal).

Mr. E. K. Muspratt said that in their experience as buyers they had hardly any difficulty, as their tests for the sulphur in pyrites agreed generally with that of the seller's chemist. He was not quite certain whether Mr. Claudet used exactly the same method which they did, which, he believed, was the one advocated in Dr. Lunge's Pocket-book, but the methods adopted must be sufficiently accurate, since the results really did not differ to any considerable extent. Mr. Westmoreland said that it might be supposed that these differences would operate in favour of uniform methods of analysis, but apparently Mr. Westmoreland objected to that inference, because forsooth the introduction of standard methods would result in work being done by rule-of-thumb. He did not know whether the Society would appreciate that reasoning, but he certainly could not. It was desirable that they should decide upon and adopt where possible uniform methods of analysis. That they should use the best method in preference to others seemed to him perfectly reasonable, and the only question was whether the Lunge method was better than others. If so, he thought that all chemists should adopt that method, and in that way they would arrive at a uniform method. The differences in results were now very small; probably because more or less uniform methods were now adopted. There was another suggestion which Mr. Westmoreland made, which he certainly thought would be rather impracticable; it was, that as the consumer of pyrites did not make use of all the sulphur for which he paid, the burnt ore should be analysed as well as the raw ore, and that then there should be a deduction made so that the consumer of the sulphur should practically pay upon the difference between the sulphur in the raw ore and the sulphur in the burnt ore. As a consumer of sulphur, he (Mr. Muspratt) should be very glad if such a system could be adopted, but he did not see how it could be done, and he was afraid that there would be greater differences than there are now, in the settlement of the sulphur tests. They frequently forgot, when discussing questions of commercial tests, that the great point was to have some uniform system and practically uniform results. If that uniform system gave too high a result, the consumers would very soon find it out and settle it in the price. This was commonly done by all who had a commercial knowledge. If any method of analysis gave too high a result, or if they found any analytical chemist gave a higher result than another, they would take very good care to discount that when making their bargain. It was very well known in the potassium tests, in settling the price of muriates, that Dr. Ulex's tests differed from the Glasgow tests by 1¼ to 2 per cent. Sometimes they bought their muriates by the German test, and they took good care not to pay the same price as if they bought by Mr. Tatlock's test. All they required as commercial men was that some method should be adopted which gave uniform results. Another suggestion which Mr. Westmoreland made was that an allowance should be made for the lead, lime, and zinc in the ore. This would entail considerable difficulty, since they would have to estimate the lead and zinc before they could decide upon the amount of sulphur to be paid for. For these reasons he did not think that the practical suggestions which Mr. Westmoreland made were of very much value. It was very interesting to have tabulated the practical experience of differences of tests which he pointed out. He hoped that the discussion would lead to a more uniform method being adopted.

Dr. HURTER said that Mr. Westmoreland had expressed an opinion that the introduction of standard methods would lead to the employment of chemists who would not have the ability nor the time to investigate methods for themselves. Now he (Dr. Hurter) must say that in works they had plenty of other matters to investigate beside methods of analysis, and he for one was always thankful when scientific men supplied them with methods, and saved them the trouble to investigate for themselves. As regards Dr. Lunge's second modification of pyrites assay, he had no doubt that Dr. Lunge would not have introduced it if he had not found that the other method now and then gave wrong results. Dr. Lunge, however, was able to defend himself, and would, no doubt, do so if he thought it worth while. Altogether it appeared to him that there was much ado about nothing. At present prices, 1 per cent. of sulphur was 3d. per ton, consequently ¼ per cent. was three farthings, and he really did not think it was worth while to quarrel so much about so little.

Mr. WESTMORELAND, in reply to Mr. Muspratt's observation that if results higher than the truth were returned, the buyers would very soon find it out, said that the variable results he had recorded had not been detected either by the buyers' or vendors' analysts, although the thing had been going on for years, and that if it were necessary he would give tonnages of parcels with vendors' and purchasers' names in support of his statement, and he believed that the errors were not detected simply because there was no personal incentive for anyone to trouble about the matter. His suggestion was not that each parcel of ore should be tested separately for zinc, lime and lead, but that a deduction based on an average analysis should be made; but if buyers preferred the present system, let it remain. Regarding "rule-of-thumb" methods, his experience differed from Mr. Muspratt's, for many serious discrepancies had arisen from the fact that tests were made by young and inexperienced chemists by what may be termed "standard methods." Published instances of this might be found in his (Mr. Westmoreland's) paper on copper tests (this Journal, February, 1886), where they could see the discordant results of works tests of copper samples (nearly all the results being obtained by the same well-known process). In reply to Dr. Hurter, he might say that until recently sulphur was 6d. per unit, and when errors of 1 per cent. and upwards were made, for years the matter was much more serious than Dr. Hurter seemed disposed to admit. Of course, now that sulphur was less valuable, the subject was not of such importance.

MR. IVAN LEVINSTEIN IN THE CHAIR.

ON THE ESTIMATION OF CAUSTIC SODA IN SODA ASH.

BY ROWLAND WILLIAMS, F.C.S.

THE author stated that the methods usually employed for estimating caustic soda in soda ash—viz., by precipitating with barium chloride, and either allowing the precipitate to subside and titrating a portion of the clear fluid with normal hydrochloric acid; or boiling, filtering, and washing the precipitate, and titrating the filtrate and washings with normal acids—gave too low a percentage of caustic alkali, due to the fact that some of it is carried down and tenaciously retained by the barium carbonate. The following method is found to give absolutely accurate results:—A weighed quantity of ash is treated with strong alcohol in a stoppered flask, frequently shaken and allowed to stand overnight; the undissolved carbonate is filtered off and washed with strong alcohol until a drop gives no alkaline reaction; the filtrate and washings are then titrated with normal acid.

DISCUSSION.

Mr. CARTER BELL said that Mr. Peter Hart had given him the process to be found in the following paper, which was considered to be both more accurate and simple than that devised by Mr. Williams. Mr. Watson Smith had also drawn his attention to his paper published in this Journal, 1882, pages 85–88, in which the subject of the retention of alkali and the conditions of such retention are fully dealt with, as well as to the accurate and very expeditious process of Winkler, described in Lunge and Hurter's Pocket-book, p. 115.

* * *

ON THE ESTIMATION OF THE RELATIVE ACCOUNTS OF CAUSTIC AND CARBONATE OF SODA IN COMMERCIAL SODA ASH.

BY PETER HART.

As a rule, the method of analysis which is quick and moderately exact is the one preferred in a works laboratory. With this view we have adopted the following method of estimating the relative proportions of caustic and carbonated soda in a sample of soda ash :—50 grains of the sample is dissolved and made up to about half or three-fourths pint of water ($\frac{1}{2}$ to $\frac{3}{4}$), a little phenolthalein added, and the test acid (1 decem = 0·5 Na_2O) slowly run in until the colour disappears. At this point all the caustic soda and *one half* the soda exisiting as carbonate has been neutralised, the number of measures—say 30—is noted. To the same solution (the soda in which now exists as bicarbonate), a little methylorange is added, and the addition of acid from same burette continued, until the usual colour reaction indicating neutrality occurs—say the burette now reads 50. Then 50 – 30 = 20 as bicarbonate which originally existed as monocarbonate in the sample. This, therefore, must be doubled = 40. This, deducted from the total number 50, leaves 10 existing in original sample as caustic soda. The first stage of this method is identical with Mr. R. T. Thompson's method (*Chem. News*, 1883, 127), but instead of using methylorange, which we prefer as being more expeditious and equally exact, he boils and adds the standard acid until the phenolphthalein is finally discolourised.

MR. IVAN LEVINSTEIN IN THE CHAIR.

ON A RAPID METHOD OF DETERMINING THE TOTAL ACIDITY IN FLUE GASES FROM VITRIOL CHAMBERS, ADAPTED FOR THE USE OF WORKMEN.

BY W. YOUNGER.

In the manufacture of sulphuric acid a test is usually made of the gases escaping at the chamber vent.

This test is necessary, both as a check upon the working of the chambers, and also for the purpose of keeping the escape within the requirements of the Alkali Act. One arrangement frequently employed for this purpose is what is called the constant aspirator, or self-registering apparatus for testing flue gases. It consists of an ordinary Bunsen's water pump and a wet meter.

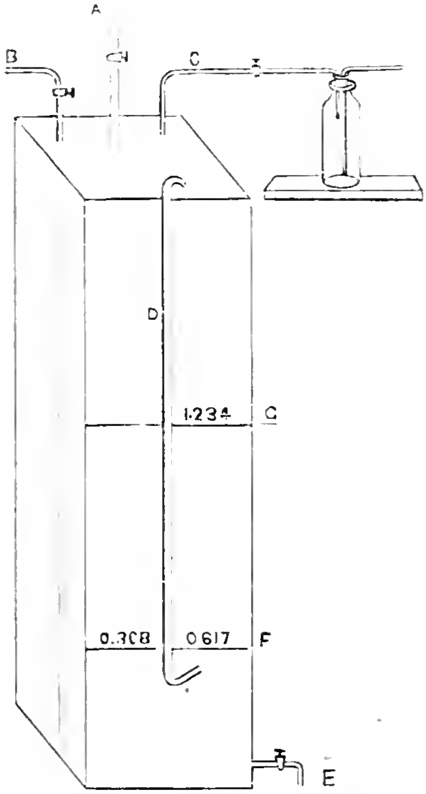
The gases are absorbed by drawing them through a measured quantity of a standard solution of caustic soda, which must be always in excess.

After taking the aspiration the solution is made up to a given volume, and a measured portion of it titrated with standard acid in order to ascertain the excess of soda left in the solution. In this way the amount of soda taken up by the gases is obtained, which after calculation is expressed in grains SO_3 per cubic foot.

This arrangement is kept constantly at work, and may be taken off once in twelve or twenty-four hours, in order to ascertain what the escape has been.

A test may be made in a similar manner to this, only using a cubic-foot box in place of a Bunsen pump, but, as this will only give you a test over a comparatively short time, say for half-an-hour or so, it is not so satisfactory as the method I have just described.

The method I am about to describe is one which was adopted for the use of the works foreman only, so that he might make a rough and ready test in order to ascertain what his escape might be.



The apparatus consists of a rectangular-shaped cast-iron box as shown in the figure. A is a water pipe for filling the box with water; B, an air pipe for allowing the air to escape; C, the tube connected to the bottle in which the aspiration is taken; D, a gauge glass for the purpose of reading off; E, the tube for running off the water in taking the aspiration.

Only one bottle is employed for absorbing. The absorbent in this case is also a measured quantity of a standard solution of caustic soda, coloured with litmus as an indicator.

In order to ascertain if the absorption of the gases be sufficiently complete for the test I had in view, a second bottle was attached containing distilled water only, when on drawing through the gases it was found that the soda in the first bottle was taken up, the solution assuming a red colour, while no acidity was shown in the second bottle containing water only.

In making a test you proceed as follows: Into a bottle are put 10cc. of a centinormal solution of caustic soda coloured with litmus. This quantity will equal 0·617 of a grain SO_3. The bottle is then coupled up to the aspirator and the gases from the chamber vent drawn through. From the top of the box down to the line marked F, represents one cubic foot; and if the solution in the bottle changed colour when the level of the water in the gauge-glass stood at this line, then the total acidity in one cubic foot of the gases would be equal to 0·617 of a grain SO_3; or again, from the top of the box down to the line marked G represents half a cubic foot, and if the solution in the bottle changed colour when the level of the water in the gauge-glass stood at this line, then the total acidity in one cubic foot would be equal to twice 0·617 or 1·234 grains SO_3, and so on, so that a table can be constructed the length of the box.

It was thought desirable that lower readings than 0·617 of a grain should be obtained, so a table was constructed down the other side of the gauge-glass, so that if a reading be not obtained when it has reached 0·617, the aspiration is stopped, the box filled up, restarted, and a reading taken down the other side. In this way readings as low as 0·308 of a grain per cubic foot can be obtained.

This is a method which makes no pretensions to any great degree of accuracy, as it was intended only for the use of the foreman to serve as a guide to him in the working of his chambers.

DISCUSSION.

Mr. R. F. Carpenter said that he had found Mr. Younger's apparatus to be very useful where foremen of works required to take rapid readings. It might be of interest to members to know that there was also another form of apparatus which seemed to him equally useful, and which had an additional advantage from the fact that the test solution used was not caustic soda, but iodine and some solvent potassium iodide. A Woulff's bottle was used, and the connection made with the exhaust by means of a thin indiarubber ball, so many squeezes of which represented a cubic foot. If one squeeze represented only four grains, the foreman then saw how many pounds of nitrate of soda were to be put into the pot, and this seemed to him quite as quick a way as that described by Mr. Younger, and it also carried the operation a little further. A knowledge of these things was a great aid in the performance of their duties.

Dr. Grossman said they were all very much obliged to Mr. Younger for bringing this apparatus before their notice, and thought it a great pity that it was not better known. It was nine or ten years since its first introduction by his (Dr. Grossman's) friend, Dr. Hurter, and the best description of it is in Wanklyn's book on "Gas Analysis." The most useful property of the apparatus was that you could easily tell how far the combustion was carried on—what fuel was used, and how much was wasted. This was a very important matter, and one which was of general use in nearly every chemical manufactory. He had been able in this way to test new furnaces in which they were blowing air through the fire instead of burning it in the usual way, and they had been able to get almost perfect combustion.

Mr. William Thomson thought Mr. Younger had not brought this apparatus forward as his own. He believed he had brought it forward to show how serviceable it was for work, and he thought simple suggestions of that sort brought before gentlemen connected with the various branches of industry were very useful. He took it to be one of the objects of the Society to bring forward any apparatus which might be overlooked by others, and which need not necessarily be something new. The arrangement of the bottle and the fact of being able to measure the heights of the liquids as they passed through the tubes, had their advantages. Mr. Younger that night had only got 19 per cent. from his air, whereas a fortnight since he obtained 22½. With regard to the other box, in which he measured the total acid passing up the chimneys, that was another useful apparatus, the application of which was most interesting to those engaged in that particular industry, where a man could stand with his neatly-appointed tap and at once weigh off the number of grains of SO_3 per cubic foot.

◆

ON A CONVENIENT MODIFICATION OF ORSAT'S METHOD FOR THE ESTIMATION OF OXYGEN.

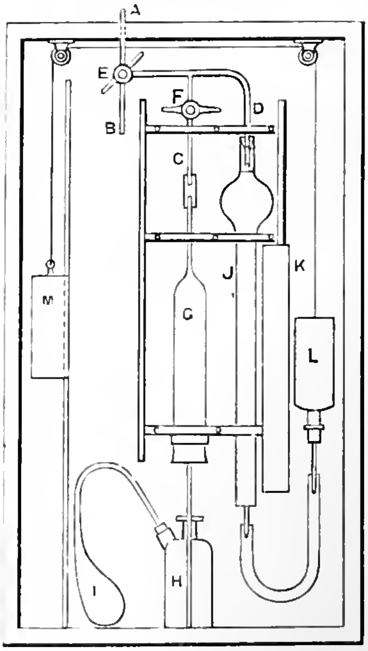
BY W. YOUNGER.

The apparatus I am about to describe to you is intended for the estimation of oxygen.

It is on the same principle as Orsat's, but of somewhat different construction.

It was first employed at the works of Messrs. Charles Tennant & Co., St. Rollox, Glasgow, but to which I have added a slight modification.

At the top of the annexed figure we have a set of tubes, one end of which, A, projects through the top of the box for the purpose of coupling it up to the source from whence the gases are to be drawn; B is another open end pointing downwards, while the other two ends, C and D, are coupled up, one to the absorbing tube, and the other to the graduated tube. E is a two-way tap, F a one-way tap. G is the absorbing tube containing the coil of copper-wire gauze; H a small Woulff's bottle containing the absorbing solution of ammonia chloride of copper; I an indiarubber ball for the purpose of forcing the absorbing solution up into the absorbing tube. J is



the graduated tube, and from zero at the bottom is graduated up to 25cc., divided into tenths, while to a mark immediately above the bulb is equal to 100cc.—the measured quantity of the gases to be operated upon. K is a scale for the purpose of reading off, which is the modification I have introduced. The lower end of the graduated tube is coupled up to a bottle L, which is inverted, through a hole in the bottom of which passes a piece of catgut knotted at the end. The catgut passes over two small pulleys, one at each corner, and to the other end of which is attached a balance-weight M, consisting of a piece of wood which slides up and down in a box. The inverted bottle L is filled, or nearly filled, with water, by lowering and raising which the gases are drawn in or expelled in making a test.

The method of using this apparatus will be apparent.

MR. B. S. PROCTOR IN THE CHAIR.

THE RECOVERY OF FERROCYANIDES FROM LEBLANC SODA LIQUORS.

BY F. S. NEWALL AND GEORGE SISSON.

So long as the Leblanc soda process continues to exist, the occurrence of ferrocyanide in the crude liquors produced in that manufacture must continue to have a very vital practical interest, inasmuch as such ferrocyanides are, when decomposed, the chief cause of the discolouration of the products. In fact, but for such ferrocyanides, the ordinary Leblanc ash could be made practically as white as ammonia ash.

Hence it is not surprising that many efforts have been made from time to time to remove or to prevent the formation of such cyanides, but all such attempts were processes of destruction, not recovery.

It might be well to state here, before going into a historical review of the subject, what the accepted theory of the formation of ferrocyanide in the Leblanc soda process is. The source is generally admitted to be the nitrogen of the mixing coal used in the balling furnace. This has been proved by using pitch or some such carbonaceous matter free from nitrogen as a substitute for mixing coal, when it was found that the balls contained little or no cyanide. The nitrogen of the air is no doubt capable of forming cyanides in presence of an alkali in a reducing atmosphere of carbonic oxide—for example in blast furnaces—but it has been shown that this is small in comparison with that formed from the nitrogen of the mixing coal, which contains generally from ½ to 1½ per cent. of N. The stages of formation of ferrocyanides can be shown by extracting ball soda with alcohol, the solutions showing cyanide of soda, and the extracted mass when lixiviated with water shows no ferrocyanide.

In 1853 Gossage took out a patent for separating ferrocyanide of sodium from other compounds of sodium in black ash liquors by means of repeated crystallisation, and if one may judge from the patent list, the subject appears to have been almost dropped till it was revived by the introduction of ammonia soda, making it necessary that Leblanc soda makers should improve the colour of their ash.

In 1866 Williamson proposed to remove the ferrocyanides by heating the liquors to 155° C. under pressure in an iron boiler, but this was given up on account of the hard crusts which formed in the boiler, rendering the process both difficult and dangerous to work.

The next process of interest was Pechiney's, which was introduced into England in 1877 by the late Mr. Walter Weldon, and consisted in adding, just before drawing the batch, sodium sulphate, which oxidised the cyanide into cyanate, and thus prevented the after-formation of ferrocyanide. Even this process leaves some ferrocyanides in the resulting liquors stated to be at least 0·03 per cent., and often 0·25 per cent. of the total alkali.

Several patents were taken out in 1878 and 1879, bearing more or less on Pechiney's, which were never worked commercially, and need not be more than mentioned here.

Gaskell in 1878 took out a patent for blowing a current of air and steam into the revolver during the working of the batch, for the purpose of oxidising the cyanide into cyanate, but the main reaction of the revolver being a reducing one, it is very difficult to make it slightly oxidising also.

In 1879 a patent was taken out by Messrs. Carey, Gaskell and Hunter for oxidising the liquors by injection of flue gases, and then pumping the liquors through coils of pipes at a temperature of 150° C., thus converting the ferrocyanide into sulphocyanate. This was a practical success so far as the destruction of the ferrocyanides went.

Mention should be made of the Thelen pan for evaporating the tank liquors, fishing and drying the salt at a temperature below 150° C., thus preventing the decomposition of the ferrocyanide, and so the discolouration of the ash.

Also of apparatus devised and patented by MacTear, for breaking into small pieces the batch as it was emptied from the revolver, thus exposing a large surface to the air. We tried this before MacTear, and found that the proportion of cyanide was much reduced.

Most of these processes seem to have expired, and the plan now is to allow the ferrocyanides to be destroyed in the calcining furnace, when a more or less red ash results; if white alkali is required, to redissolve this and separate the oxide of iron and other impurities by filtration or settling.

We will now describe a process which we have worked satisfactorily at Washington, and which we believe to be quite new, and as it has not been patented, we give it now without reservation, and for what others may consider it worth.

In making soda crystals direct from tank liquors, that is without previous calcination, it was found, naturally enough, that the whole of the ferrocyanide was concentrated in the mother liquors, which, on being evaporated and dried in the usual way, gave a weak alkali—not as is usually the case white, but a dark red or brown, which necessitated redissolving it to produce white alkali.

The amount of soda ferrocyanide was sometimes as much as 5 per cent. on the total alkali present, so that it seemed worth while to separate and use it in some way, and after very many trials the following process was adopted :—

The mother liquor from the crystals was run into a cast-iron cylinder, fitted with an agitator, and treated with a zinc salt in excess of the ferrocyanide present, and any caustic soda present in the liquor removed by CO_2 gas blown in till some bicarbonate of soda was formed. As a matter of fact the caustic rarely reached 1 per cent. on account of the thorough previous carbonation of the tank liquors by flue gases.

The zinc salt thus added completely removed the ferrocyanide from solution as zinc ferrocyanide, the latter being filtered off by means of a filter-press, and washed free from soda. The filtrate on being boiled down and calcined gave white alkali direct. The cakes in the press, consisting of zinc ferrocyanide, were treated with a boiling solution of caustic soda so as to obtain the ferrocyanide in a soluble form, and filter pressed, giving cakes of zinc oxide. Lastly, the solution of sodium ferrocyanide was added to a ferric salt — made from copperas, nitrate of soda, and H_2SO_4—giving a pure Prussian blue which was filter pressed into paste for the use of papermakers, etc.

The recovered ZnO in cakes from the press was made into a cream with water or the crude mother alkali liquors, and used for treating a fresh portion of liquors. Thus the zinc can be used over and over again, the mechanical loss having to be made good with fresh zinc salt.

It will be noticed that in the above process an equivalent of caustic soda is used in the treatment of the zinc ferrocyanide cakes, and as caustic soda is rather an expensive base, it was thought desirable to find a cheaper one, this being found in a soluble sulphide of calcium, large quantities of which we were then and are still making.

The calcium sulphide acts quite easily and completely on the zinc ferrocyanide, producing zinc sulphide and calcium ferrocyanide, which is quite soluble, and can be easily separated by a filter-press, and used equally well for making paste blue.

There is another form of cyanide occurring in such liquors—viz., sulphocyanate. After the removal of the ferrocyanide, the sulphocyanate still remains, and on acidifying and adding ferric chloride, a blood-red precipitate is produced, without any blue precipitate: but as this salt remains perfectly white on calcining, or rather is probably converted into sodium carbonate, no efforts were made to remove it.

Of course it will easily be seen that prussiate of potash could be made instead of Prussian blue, by treating the calcium ferrocyanide solution with sulphate of potash, filtering off the calcium sulphate and separating the prussiate of potash by crystallisation in the usual way.

The sample of blue on the table is from many tons made by the calcium ferrocyanide method.

The process depends on—

1. The stability of zinc ferrocyanide in a cold solution of soda, free from caustic.

2. The readiness with which zinc ferrocyanide is decomposed by caustic alkali or alkaline sulphides, or calcium sulphides.

The tests we used were—

For caustic, a solution of barium chloride, about twice normal, added in excess to a portion of liquor, and well shaken. A few drops of an alcoholic solution of phenol-phthalein gives a pink colour as long as any caustic is present.

For ferrocyanide, a portion of liquor filtered, acidified by HCl, a drop or two of ferric chloride added will give a blue precipitate so long as any ferrocyanide exists in the liquor. When all is removed, a clear red colour of ferric sulphocyanate is produced.

In treating zinc ferrocyanide with calcium sulphide, the reaction is complete when a well-boiled portion filtered, shows slightly black with lead acetate.

The ferrocyanide in the liquors was generally estimated by acidifying, and precipitating with ferric chloride, and washing the Prussian blue precipitate, decomposing with a little caustic soda, and titrating with standard permanganate of potash, standardised by pure crystallised potassium ferrocyanide.

DISCUSSION ON DR. SMITH'S PAPER (READ AT FEBRUARY AND MARCH MEETINGS).

MR. JOHN PATTINSON asked if Dr. Smith's method was applicable to the analysis of organic mixtures: it seemed to him that it would only be practicable by it to determine the amount of a single known substance where nothing else oxidisable by permanganate was present. He referred to Dr. Smith's strictures on the use of permanganate in water analysis, and pointed out that though the results were empirical, yet it afforded good comparative estimates, especially in successive examinations of the water from a single source. He had formerly employed it for estimating organic matter in the effluent water from paper works, and other sources, and had found it give very satisfactory results. He noticed that Dr. Smith spoke of the precipitated oxide as having a composition corresponding to the formula MnO_2. He had formerly experimented on the precipitation of manganese in this form with a view to its determination, and had found great difficulty in obtaining it as MnO_2. On reducing permanganate with alcohol, the precipitate contained only about 84 per cent. of the available oxygen corresponding to MnO_2: and on precipitating manganese salts in presence of bleaching powder or bromine, the precipitates always exhibited a deficiency of oxygen until the idea of adding ferric chloride or zinc chloride suggested itself.

DR. SMITH said the method was as yet in an experimental state: ultimately, he hoped to be able to determine the carbon dioxide produced in the oxidation, in which case there would be two data, giving the means of determining each substance in a mixture of two known bodies. Of course the nature of the substances present would have to be known before the method could be applied. Former methods making use of permanganate had been in error owing to the loss of oxygen, which he had been able to overcome. He could confirm Mr. Pattinson's statement that great difficulty is experienced in oxidising a manganous salt completely to the form of MnO_2 by means of permanganate, without employing a certain excess of the reagent.

MR. DUNN had formerly had occasion to make some experiments, which bear somewhat upon the question of the composition of the precipitate. He had boiled together solutions of permanganate, and of manganese sulphate. He found that when the respective molecular proportions of the two were as 2 to 1, the reaction was represented by the equation—

$$2KMnO_4 + MnSO_4 = 3MnO_2 + K_2SO_4 + O_2.$$

and that as the proportion of the permanganate was lessened, so also was the amount of oxygen evolved, till when the proportions were two molecules to three, there was no oxygen given off, and the reaction was as follows:—$2KMnO_4 + 3MnSO_4 + 2H_2O = 5MnO_2 + K_2SO_4 + 2H_2SO_4$. Analysis in all these cases showed the precipitate to consist of MnO_2. When the proportion of permanganate was lessened (or that of the sulphate increased) beyond this, still no oxygen was evolved, the whole of the available oxygen of the permanganate going to form an oxide, but this oxide invariably now contained less oxygen (or rather, perhaps, more manganese) than corresponded with MnO_2. Possibly this arises from the feebly-acid nature of MnO_2, which enables it to decompose some of the sulphate, taking its MnO as base; and probably the effect of Mr. Pattinson's addition of ferric or zinc chloride, is due to his substitution of another base, enabling the whole of the manganese to play the acid part as dioxide. It would be interesting to know whether Mr. Pattinson's precipitates contain any iron or zinc. When the permanganate, in the above-quoted experiments, was in the proportion of four molecules to one of sulphate, the first of the above reactions still took place, the whole of the excess of permanganate remaining unacted on. From this he was inclined to suppose Dr. Smith in error in attributing the loss of oxygen in his earlier experiments to action of dioxide on permanganate, considering it rather due to the action between permanganate and manganese sulphate, when the former was present in greater proportion than that represented by the second of the above equations. He desired lastly to enter a mild protest against Dr. Smith's use of the word "normal." That word having been appropriated to signify a solution containing the equivalent in grms. of some substance per litre (though he admitted there was occasionally a little looseness exhibited in determining on what basis the solution should be made, whether, for example, grms. of permanganate, or grms. of available oxygen per litre), it seemed a pity to use it for solutions of arbitrary strength, where the word "standard" would be equally applicable.

Dr. Smith thought that Mr. Dunn's results were explicable, if the acidity or alkalinity of the solutions was taken into account. He had shown that there was no less of oxygen in neutral or alkaline solutions, and it would be noticed that as the proportion of permanganate increased, the acidity of the solution, after reaction, diminished, till at the proportion of $2KMnO_4$ to one of $MnSO_4$, the free acid was neutralised, and no addition of permanganate beyond the actual point of neutrality would cause any additional loss of oxygen. He agreed, however, with Mr. Dunn that the acid character of MnO_2 had much to do with the reaction, and was rather inclined to think that the formation of a compound such as $K_2Mn_5O_{11}$, would mark the final stage in the decomposition (although, not having tried Mr. Dunn's experiment, he could not speak definitely), and that doubtless the formation of corresponding compounds with zinc and iron, explained Mr. Pattinson's results; but that could not be the explanation of the action of the ferric salt in stopping the evolution of oxygen in his (Dr. Smith's) method, for in that case zinc, like iron, should have been efficient, which was not at all the case. In regard to the use of the word "normal," it was usual on the Continent to apply the term to such permanganate solutions as these mentioned in the paper. They were of convenient strength; and if you adopted the other plan you must often, for convenience, make use of half, quarter or deci normal solutions.

Errata.—In Dr. J. H. Smith's paper (Feb. Number), p. 101, 1st column, 23rd line, *for* "excess" *read* "access." P. 105, 1st column, the equation should read $K_2Mn_2O_8 + nMnO_2 + H_2SO_4 = (n+2)MnO_2$, etc. P. 107, 2nd column, 13th line, *for* "1cc." *read* "1·1cc." P. 109, 1st column, 10th line from bottom, *for* "108cc." *read* "51cc."

MR. J. NEILSON CUTHBERTSON IN THE CHAIR.

ADDENDUM TO DISCUSSION ON MR. SUTHERLAND'S PAPER ON "SCALE TESTING" (THIS JOURNAL, VI. 271)

Mr. Hunter agreed with Mr. Hamilton as to the changes which had come over the paraffin industry. There was no doubt that only one or two unimportant works were now producing scale likely to go into the market as "scale." All the larger works were now making preparation for making candles, and in that way were using up their own scale. It was, therefore, not such an important question as it was a few months ago. Referring to the presses adopted, the number or size of men had always, he said, been an unknown quantity in testing scale. Definite results could never be got even by screwing the press up to a certain point, as it was well known how results obtained by screw-presses varied. A year or two ago his colleagues Mr. J. Falconer King and Mr. Wm. F. King had worked out a press which fulfilled all the purposes required. It was exceedingly simple, but very efficient, and the pressure exercised upon a given surface could always be got to an ounce. It consisted simply of a bent railway iron bar with a steel face let in. There was also a long beam with a knife edge working on the steel face, and on the end of the beam weights were hung. The screw, which was used only for keeping the beam in a horizontal position, rested on the top of the disc, and the conditions were the same in every respect as in the present press, except that there was no friction whatever. The direct pressure exerted on the square inch could be weighed to an ounce, and in that way it was a distinct advance on any other method adopted in scale testing. All the necessary precautions alluded to by Dr. Wallace were adopted, and the press could be arranged to any required temperature by means of a trough of brine, or glycerine, surrounded by a freezing mixture, circulating through the plates. He was in the habit of pressing scale at a temperature of 60°, and no difficulty was experienced in keeping the temperature constant. The press was, in his opinion, a great advance upon any other method; that at present adopted by the oil trade was very absurd.

◆◆◆

DISCUSSION ON MR. STEUART'S PAPER ON "BROXBURN PETROLEUM" (THIS JOURNAL, VI. 128).

Mr. Hamilton assumed that it would be well known that Broxburn had been surrounded by five or six different shale mines all on fire, and that consequently there was a certain amount of that shale oil in the strata which was constantly percolating through it. He regretted Mr. Steuart's absence, as he should like to have known whether or not this brine and petroleum occurred in the same place, or whether the petroleum did not occur near some place where a shale fire had been raging, and was it not simply the result of distillation of the shale by means of the destruction of another part? The oil more resembled an artificially-distilled oil than any natural oils he ever saw.

Mr. Hunter concurred in the remarks of the previous speaker. He had seen and examined this so-called petroleum. There was not the slightest doubt about it being paraffin oil that was discovered, and it was also perfectly well-known that in different directions where fires had occurred it was semi-solid paraffin. Mr. Steuart mentioned in his paper that it was of high viscosity to pump. It was certainly of high viscosity, as it was not petroleum, but partially filtered oil. The brine to which reference had been made was similar to that found in pits in many other places, and was in no way proof of petroleum.

Dr. Wallace said that when Boghead coal was first discovered, there was also a discovery at Binnie Quarry, near Bathgate, of a kind of bitumen which, on distillation, gave a large quantity of oil, and that bitumen was certainly an indication that petroleum might exist in some of the strata. The occurrence of that bitumen was, of course, before the paraffin industry commenced, or at the very commencement of it. He thought, therefore, that while it might be correct that this particular sample of petroleum was the result of fire in the mines, it was not at all impossible that petroleum might be found in Scotland. The occurrence of bitumen in Binnie Quarry was a certain indication that there was something of the kind in the strata.

Mr. Steuart, in reply, said that Mr. Hamilton suggested that the oil was distilled from shale by the burning mines of the neighbourhood. From the circumstances of the case this seemed quite impossible. If there had been workings in the lower seams into which the oil could have percolated, then something might have been said in favour of this view; but there were no such workings. When a bore was sunk through the strata in question, water and gas rose to the surface, showing the high pressure under which fluids in them existed. To saturate such a stratum with crude oil the oil vapour must have been produced under tremendous pressure. No burning workings could produce a pressure worth mentioning, as there would always be easy outlet into the workings themselves. In 1883 there was a fire in old workings within half a mile of where we found the petroleum, but it was put out in a fortnight. It was quite inadequate to produce either the crude oil or the pressure required. In the two places, about 950 yards apart, where the petroleum was found, it was the same stratum that yielded the petroleum. There was no crude oil seen in the old workings in which the fire was, and that the crude oil should have appeared at a considerable distance away, in a stratum that lies 85 fathoms lower, seemed quite absurd to anyone that knew anything about this mineral field. That the oil should have been produced by more distant fires, such as North Greendykes open cast, or Meldrie, seemed even more absurd. It was possible, perhaps, that this petroleum was produced by distillation of shale, but not from the puny fires connected with human operations, or in recent times; but in the bygone ages when the coal and shale of some localities here were coked by the subterranean heat. The smell, bromine-absorption, and other properties, indicated a natural petroleum, and not a crude shale oil. The amount of solid paraffin in it was no argument against it being a natural petroleum, for in nature we have all grades represented between the solid ozokerite of Binny Sandstone Quarry, mentioned by Dr. Wallace, with melting point 200° F., and the Russian petroleum, which has no solid paraffin. There is only one shale worked in this mineral field —namely, the Broxburn seam.

DISCUSSION ON MR. TATLOCK'S PAPER ON "THE ESTIMATION OF SMALL PROPORTIONS OF IRON" (THIS JOURNAL, VI., 276).

Mr. E. C. C. Stanford pointed out particularly the great value in any colour reaction of being able to dissolve it and bring it right out of the solution, because the trouble with many colouring matters was the difficulty of seeing them, especially where the solutions were—as they often are—rather turbid; and where the colour was taken out in another liquid, it afforded an opportunity of comparison which could not be shown in any other way.

Mr. J. Christie had pleasure in bearing testimony to the accuracy and beauty of this test, as applied in public works. For a great many years he had adopted this method for testing crystal alums and sulphate of aluminium, and he had found the great advantage of this test over the Prussian blue iron test, that was formerly used. One great novelty to him in this paper was the application of ether, which seemed to concentrate the colouring matter and increase the delicacy of the test. He had not tried this, but would do so in order to see what improvement it was over the old method of oxidising the iron, which existed, as a rule, in crystal alum in the ferrous condition.

NEW METHODS OF ESTIMATING ARSENIC IN PYRITES, Etc.

BY JOHN CLARK, PH.D., F.C.S., F.I.C.

Of the various processes for the estimation of arsenic in pyrites, the one which is based on the conversion of the arsenic into an alkaline arseniate by fusion with nitrate of potash and carbonate of soda, seems to have found most favour, especially that modification which consists in precipitating the arsenic as arseniate of silver and titrating the silver by Volhard's method. In most cases this is an excellent and reliable process, especially where the quantity of arsenic is considerable, as has been clearly demonstrated by Leroy McCay's experiments (*Chem. News*, *48*, 7), but it is open to two objections. 1st, The liability to estimate phosphoric acid as arsenic: and 2nd, The difficulty of determining very small quantities of arsenic in pyrites, owing to the large proportion of alkaline salts, and the solubility of the arseniate of silver in nitrate of ammonium, which is greater than Mr. McCay's remarks (*Chem. News*, *48*, 7) would lead one to suspect.

These objections may to a large extent be avoided by the following precipitation process, which is specially applicable to pyrites rich in sulphur, such as is used in the manufacture of sulphuric acid, and well adapted for the estimation of small quantities of arsenic.

Precipitation Process.

A weighed quantity of the pyrites (about 50 grains, or 3grms.) in a fine state of division is mixed in a platinum crucible with four times its weight of calcined magnesia and sodium hydrate free from arsenic (prepared by grinding together in a porcelain mortar equal parts of freshly-calcined magnesia and pure sodium hydrate), and the open crucible is placed for about 10 minutes over a moderately low Bunsen's flame. The mixture in the crucible shrinks somewhat, but no liquefaction takes place, and the contents of the crucible are easily extracted with boiling water. After the removal of the insoluble, the filtrate, which should be green in colour, owing to the presence of a little iron, is acidified with HCl, which causes an abundant disengagement of H_2S, and the solution, which is now nearly colourless, is boiled for a few minutes, when the sulphide of arsenic will separate along with a little sulphur. In most cases the whole of the arsenic is thrown down in this way, but to ensure complete precipitation it is always advisable to saturate the solution with H_2S gas. The precipitate is then thrown upon a filter, washed, the sulphide of arsenic dissolved out with ammonia, and the ammoniacal solution evaporated to dryness on a water bath. The residue is treated with a little strong nitric acid, in which everything dissolves, and the arsenic either estimated as ammonio-arseniate of magnesia or precipitated as arseniate of silver, and the arsenic calculated from the silver as determined volumetrically by Volhard's process, or gravimetrically by cupellation as recommended by Richter.

This process, which has been in use in my laboratory for some time, gives very accurate results, as I have proved by experiments made on pyrites mixed with pure sulphide of arsenic. On account of the large quantity of pyrites which can be manipulated without inconvenience, and the concentrated form in which the arsenic is obtained, very minute quantities can be determined in this way.

By fusion with nitrate of potash and carbonate of soda, with subsequent precipitation as arseniate of silver, I have found it impossible to estimate the arsenic in pyrites containing only about 0·1 per cent., whereas by the process which I have just described 0·03 per cent. can be determined without difficulty.

Of the other methods of estimating small quantities of arsenic in pyrites, those involving distillation are the most important. These processes are all based on the conversion of the arsenic into arsenic acid, its subsequent reduction to arsenious acid, and its volatilisation as chloride. Emil Fischer (*Ber. d. Deut. Chem. Ges.* 1880, 1778) was the first to show that the arsenic acid could be reduced and converted into chloride by ferrous chloride and hydrochloric acid, and afterwards either precipitated as sulphide or titrated with iodine. The results so obtained are described as accurate. But F. Hufschmidt (*Ber. d. Deut. Chem. Ges.* xvii. 2245) found it necessary to use HCl gas, or strong solution of HCl instead of the 20 per cent. HCl employed by Fischer, as otherwise the whole of the arsenic is not volatilised, even after ten distillations. Messrs. Classen and Ludwig (*Ber. d. Deut. Chem. Ges.* 1885, 1104) also insist on the necessity of using HCl gas or strong HCl, and they recommend sulphate of iron or the double sulphate of iron and ammonia as the reducing agent.

In carrying out the process the pyrites is either dissolved in nitric acid and the excess of nitric acid removed by repeated evaporation with sulphuric acid, or the arsenic is converted into arsenic acid by the action of caustic potash and chlorine, and the chlorate decomposed by HCl. After the removal of nitric acid or decomposition of the chlorate, the arsenic is converted into chloride by means of HCl and the ferrous salt. In either case the removal of the last traces of the oxidising agent occupies a good deal of time, and the presence of free sulphuric acid is objectionable, if the arsenic is to be titrated with iodine, as sulphurous acid is apt to be evolved when the distillation is carried too far.

In the new process, which I am about to describe, the oxidation of the arsenic is effected without the use of nitric acid or chlorine, and there is a considerable saving of time. On a former occasion I pointed out that when pyrites is heated with an intimate mixture of sodium hydrate and calcined magnesia, the sulphur is oxidised to sulphuric acid. Under the same conditions the arsenic is completely converted into arsenic acid, and can be afterwards reduced and distilled over as chloride. In the determination of sulphur, I recommended the use of the muffle to avoid the sulphur from the gas, but in estimating arsenic I prefer the Bunsen flame, as it is more generally available.

New Distillation Process.

The finely-pulverised pyrites (generally about 25 grains or about 1·7 gramme) is introduced into a platinum crucible with six times its weight of a mixture of pure sodium hydrate and calcined magnesia (prepared as above described) and well stirred with a glass rod. The open crucible is then placed over a moderately low Bunsen flame for a hour, at the end of which time oxidation is complete. The contents of the crucible, which have not fused, but simply shrunk in bulk, are easily broken up with a spatula, and transferred to an ordinary wash bottle flask, moistened slightly with water to prevent the evolution of too much heat, and then dissolved in strong HCl. For this purpose I usually employ 1000 measured grains, or about 70cc. The crucible is also washed out with strong HCl, and the contents of the flask are heated gently till there is no further action. The flask, which is fitted with a funnel tube, having the end drawn to a point and dipping under the liquid, is then connected with a small glass worm condenser, to the end of which a straight chloride of calcium tube is attached, and by means of the funnel tube a considerable excess of the reducing agent, dissolved in strong HCl, is introduced. The reducing salt,* which I prefer for this purpose, is cuprous chloride,

---

* Since reading this paper I have received a letter from Professor Dittmar, stating that he has been in the habit of using cuprous chloride for the reduction of arsenic acid, and although he has not published this in any journal, it will be found in his Exercises on Quantitative Analysis, page 94.

because it forms a very soluble double salt with chloride of sodium, and its reducing action is at least equal to that of the ferrous salts. A mixture of cuprous and ferrous chloride obtained by dissolving copper in ferric chloride is also an excellent and suitable reducing material. The contents of the flask are then slowly distilled into water for an hour, when a fresh quantity of strong HCl (about an ounce) is introduced, and the distillation continued for another half-hour. The whole of the arsenic will now be found in the receiver, but it is always advisable to add a little more HCl, change the receiver, and test the distillate. The arsenic is then precipitated as sulphide, and collected on a weighed filter, or it is titrated with iodine in the usual way. When the quantity of arsenic is large, I prefer the iodine process, but it is more satisfactory to precipitate minute quantities of arsenic as sulphide.

For the purpose of verifying the accuracy of this process, and testing its suitability for the determination of arsenic in various substances, the following experiments were made :—

I. Two quantities of arsenious acid, each weighing 3·96 grains, were fused with magnesia mixture, distilled with cuprous chloride, and titrated with iodine, with the following result :—

	Per cent.
(*a*) Arsenious acid	3·94
(*b*) „ „	3·90

II. An arseniate of soda which contained no arsenious acid, and gave by the ordinary precipitation process 50·03 per cent. of arsenic acid, yielded when distilled with cuprous chloride and titrated with iodine :—

	Per cent.
(*a*) Arsenic acid	50·15
(*b*) „ „	50·33
(*c*) „ „	50·00

III. A sample of Kupper-nickel fused with magnesia mixture, and distilled with a mixture of cuprous and ferrous chloride, gave :—

	Per cent.
(*a*) Arsenic weighed as sulphide	40·06
(*b*) „ „ „	40·06
(*c*) „ titrated with iodine	40·35

The same sample fused with nitrate of potash and carbonate of soda, precipitated as arseniate of silver, and titrated with sulpho-cyanide, gave :—

	Per cent.
Arsenic	40·13

IV. A sample of Spanish pyrites gave the following results with different processes :—

	Arsenic, per cent.
(*a*) Clark's precipitation process weighing as ammonia arseniate of magnesia	0·55
(*b*) Clark's precipitation process, combined with precipitation as arseniate of silver and titration with sulpho-cyanide	0·57
(*c*) Clark's distillation process, weighing the arsenic as sulphide	0·56
(*d*) Clark's distillation process, weighing the arsenic as sulphide	0·56

V. In another pyrites used in the manufacture of sulphuric acid, and certified by a well-known French chemist as free from arsenic, I found the following results by different processes :—

	Arsenic, per cent.
Clark's precipitation process	0·119
„ „ „	0·119
Clark's distillation process	0·117
„ „ „	0·112
Fusing with KNO_3 and precipitation as arseniate of silver	0·008
Fusing with KNO_3 and precipitation as arseniate of silver	None.

The importance of estimating correctly small quantities of arsenic will be best appreciated by those who know the difference in the commercial value of a pyrites which is absolutely free from arsenic, and one which contains even a minute quantity.

The distillation process can also be applied conveniently for the estimation of arsenic in metallic copper. As far back as 1863 Odling (*Chem. News*, No. 189, p. 27) pointed out that metallic copper dissolves in ferric chloride, and that when the solution is heated the chloride of arsenic distils over, and can be detected in the distillate. In discussing Pattinson's process (*Chem. News*, vol. xlv. p. 218) Gibb refers to the use of this method for the quantitative estimation of the arsenic, but I am not aware that the details of the process have been given, or the results obtained published. The following is an outline of the process which I adopt. 100grs. of the copper in the form of shot or turnings are heated gently with a strong HCl solution of ferric or cupric chloride (containing about 200grs. of iron or copper and free from arsenic) in the same apparatus that I employ for pyrites, and the vapour which comes off, after passing through the condenser, is collected in water. After all the copper has dissolved, which usually takes about an hour, an ounce of strong HCl is added by the funnel tube, and the distillation continued for half-an-hour. The receiver is then changed, a fresh quantity of HCl added, the distillation continued, and the distillate tested. The arsenic is then precipitated as sulphide and collected on a small weighed filter.

To test the accuracy of this process, Mr. Inglis, the chief of the Tharsis Company's Laboratory, very kindly furnished me with various qualities of copper, which had been analysed in the Tharsis Company's Laboratory in another way.

The following are the results :—

	Clark. Arsenic per cent.	Tharsis Compy. Arsenic per cent.
No. 1. Tough ingot copper	0·11	0·12
„ „	0·11	0·13
No. 2. B.S. copper	0·02	0·04
„ „	0·024	0·03
No. 3. Tough cake	0·68	0·71
„ „	0·65	0·71
No. 4. Tough cake	0·27	0·33
„ „	0·29	0·32

These figures, which agree closely with those obtained by the chemists of the Tharsis Company, who may be regarded as specialists, speak for themselves, and indicate the accuracy with which the arsenic in copper can be estimated by the distillation process, and perhaps it is only proper to mention that I was not aware of the Tharsis Company's results till my analyses were completed.

In conclusion, I would only add that in my opinion these distillation processes occupy less time than any other known method for the estimation of arsenic in pyrites or copper, and they are inferior to none in point of accuracy.

DISCUSSION.

Mr. R. R. TATLOCK considered that any method—if it was at all accurate—for the estimation of small proportions of arsenic in pyrites, would be hailed, at the present time, with satisfaction, especially when pyrites, which was alleged to be arsenic free, was beginning to make its appearance as against ores, in which they had been accustomed to find great quantities of arsenic. No doubt could exist regarding Dr. Clark's statement on the older methods, particularly those which were based upon fusion with nitrates, which, if applied to such ores as the Spanish ores (used to such a large extent in this country), would give excellent results, but when applied to ores containing only minute quantities, seemed utterly to fail, and to this fact he could testify from recent experience of them. Dr. Clark had, in his opinion, put together a series of operations which justified him in recommending his process, as the combined process was one certain to give—from what he had seen of it—very accurate results. There was all the difference possible between pyrites containing very small quantities of arsenic, and one which was entirely arsenic free, so much so that a very minute proportion, even 0·01 per cent., would be sufficient to disqualify it for sale as arsenic-free pyrites. There seemed little doubt that this combined process would give accurate results when applied to pyrites containing such very minute proportions; and the substitution of cuprous chloride for ferrous sulphate was, in his opinion, a very important one, as there were great objections to ferrous sulphate which had not been enumerated.

Dr. **Clark** pointed out that by this process it was quite easy to detect arsenic in commercial caustic soda. It was well known that a great deal of caustic soda was made with pyrites vitriol, and lately he had been enabled to prove, in caustic soda, as much as 0·02 per cent., which seemed to escape the various processes through which the soda was passed. It was absolutely necessary, therefore, in working this process, that the various materials employed should be tested for their absolute purity from arsenic.

◆◆◆

NOTE ON AN IMPROVED APPARATUS FOR THE MANUFACTURE OF REFINED PARAFFIN WAX.

BY R. TERVET, F.C.S.

So far as I am aware, there has been nothing of a practical nature brought before the Society, dealing with the manufacture of refined paraffin wax. In asking you to consider the merits of the apparatus devised by myself for that purpose, it will perhaps be necessary to briefly describe some of the more common methods and arrangements in use. Before doing so, however, I will ask your attention to the nature and composition of the substance as we find it in commerce.

It is well known that crude paraffin oil, as distilled from shale, is a series of oils differing from each other chiefly by gradual increments of increase in boiling point and specific gravity, and a parallel decrease in vapour tension, etc.

The various refined oils, which we find in commerce, are fractions of the crude oil, and take the form of burning oil, lubricating oil, etc. They have, therefore, corresponding compositions, only limited by their mean density. The solid portion of the oil—that is, the paraffin scale—is also a fraction of the crude oil, and is separated at one or other of the several stages, in the process of refining, by cooling and crystallising. If we fractionate this solid paraffin by distillation or fusion, we find it also to be a mixture of bodies having a gradual increasing melting point and specific gravity.

When these fractionations are conducted so as to give an equal quantity in a given time, for each fraction, it will be found that the several fractions differ, and increase by equal increments, whether it be for the specific gravity of an oil or the melting point of a paraffin. The several fractions do not, however, by any means represent an oil or a paraffin having constant conditions, but rather systems, having all the characteristics of the original body, only limited by being isolated from the extremes.

The ranges of temperature through which the melting points of a paraffin scale run, differ with different crude oils. The following numbers may be taken as representing the composition of a paraffin scale derived from a well-known shale:—

Analysis of Scale No. 1.		Analysis of Scale No. 1.	
5 per cent. Fractions.	Melting Point.	5 per cent. Fractions.	Melting Point.
No. 1	93·0	No. 11	114·5
2	95·0	12	116·0
3	97·0	13	118·0
4	199·0	14	120·5
5	100·0	15	123·0
6	103·0	16	123·5
7	105·5	17	125·0
8	108·0	18	126·5
9	110·5	19	127·0
10	112·5	20	128·0

These figures show all the paraffin scale contained in the crude oil available for the manufacture of refined wax suitable for candle making. The oil refiner separates the scale from two or more fractions of the oil, which yield scales of different melting points. The following figures may be taken as representing the composition of the above when separated from two fractions of the oil:—

Analyses of Scale.	No. 2.	No. 3.	Analyses of Scale.	No. 2.	No. 3.
5 per cent. Fractions.	Hard Scale.	Soft Scale.	5 per cent. Fractions.	Hard Scale.	Soft Scale.
	Melting Point.	Melting Point.		Melting Point.	Melting Point.
No. 1	101·0	80·0	No. 11	120·0	99·0
2	106·0	83·0	12	120·5	101·5
3	108·0	86·0	13	121·0	103·0
4	110·0	88·0	14	122·0	105·0
5	112·0	89·0	15	122·5	107·0
6	112·5	91·0	16	123·5	109·5
7	114·0	93·0	17	125·0	112·0
8	116·5	95·0	18	127·0	114·0
9	117·5	96·0	19	129·0	116·0
10	119·0	97·5	20	130·0	118·0

The manufacture of wax is simply a process of fractionating, having for its end the separating of the oil and the softer or more readily-fusible portions of the scale. To see this fully, we have only to compare the composition of the refined substance with the crude material. And for this purpose I have tabulated three analyses of refined wax of different melting points. (See table top of following page.)

These analyses show that the melting points of the more fusible constituents are more akin to the mean melting points of the wax than the corresponding fractions in the crude scale.

There are a great number of methods in use for the refining of paraffin scale, which differ considerably in detail. But they may be divided into two processes, which are distinctly different in their mode of treat-

ANALYSES OF REFINED WAX.

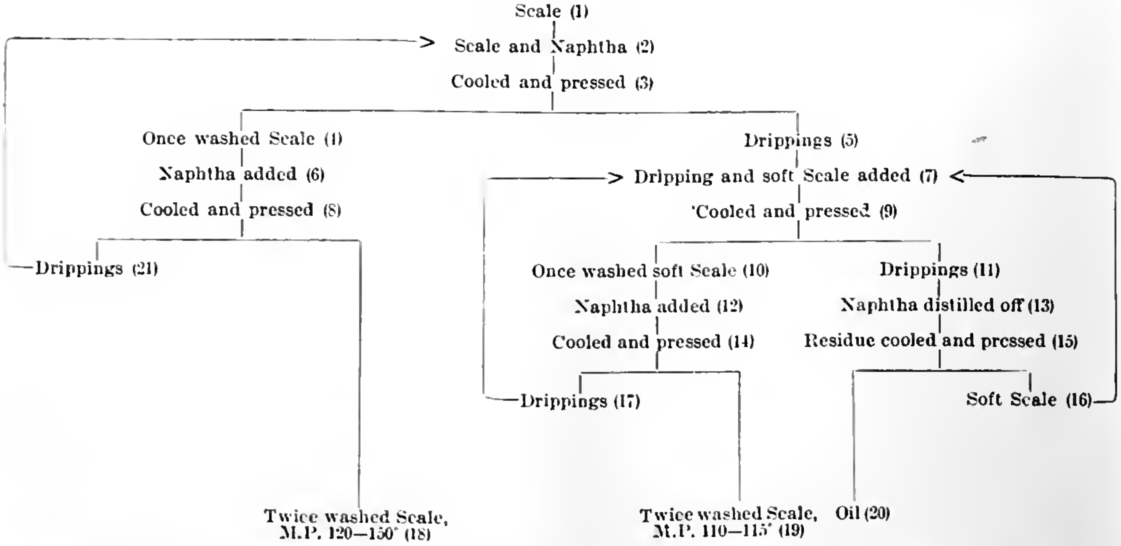
ment. We have first the naphtha process, which depends upon the solvent power of the naphtha for dissolving out the oil and that portion of the scale which requires to be removed in order to attain that melting point which may be required for any given quantity of wax.

DIAGRAM A.



In carrying out this process in practice, the scale is melted and a given proportion of naphtha added. The mixture is either allowed to cool in suitable vessels, or it may be cooled by artificial means. The cooled mixture is subjected to hydraulic pressure, when the objectionable portion is carried away by the naphtha. This operation is twice or three times repeated, or until the desired degree of purity is obtained. The explanatory diagram below will make the process clear.

As it is necessary to use a considerable proportion of naphtha in the above process, and as naphtha is a very powerful solvent for paraffin, a modification of the above is to use less naphtha, and hot hydraulic press the mixture; in other respects the process is much the same.

The other method of refining is what is called the "sweating process," in which no naphtha is used. The purification of the paraffin scale is effected by exposing the recrystallised paraffin scale to a temperature which must depend upon the fusing point of the first 10—15 per cent. of its bulk. The heat liquefies this portion, and it acts as a vehicle in carrying away that portion which requires to be separated.

As it is in relation to this latter process that my improvements have been suggested, I shall deal with the working details and the arrangement of plant as it is in some of the principle refineries, a rough outline of which is shown on sketch.

The crude paraffin scale is melted and heated to a temperature of 170—180° F., after which it is allowed to repose until every trace of water and separable impurity has settled out, the presence of which would hinder crystallisation. It is run into cooling pans which hold from one to two gallons; these pans are generally furnished with overflows, and are arranged as shown at A in Fig. 1. A stream of the melted paraffin is directed into the top pans by the taps *b*, and continued until the whole vertical series is full. They are then left to cool very slowly in order to promote crystallisation. When cold, the solid cakes of paraffin are taken out of the pans and placed in the ovens, which are fitted with shelves, the latter having a slight inclination to the one corner, and on which is laid a coarse mat of cocoa fibre to prevent the paraffin from being in direct contact with the metal surface. The cakes are exposed to a given temperature until the desired degree of purity and melting point is attained, the source of heat being a course of steam pipes laid on the floor of the ovens. The portion that has been fused out of the paraffin in the course of sweating is again treated in the same manner, only at a lower temperature suited to its mean melting point. The drainings from this latter cannot again be very profitably sweated, as it contains the whole of the oil originally present in the scale, and also the greater proportion of the paraffin of low melting points. It is, therefore, cooled in a separate series of pans, and then hydraulic pressed to get rid of the oil. The solid pressed paraffin obtained is either returned to the next make of crude scale, or it may be finished off separately as a low melting point wax, the proximate composition of which is shown in analysis No. 6. It is usual to allow a certain proportion of the paraffin of intermediate melting points to pass to this stage, in order to give solidity and maintain a suitable melting point for the finished product.

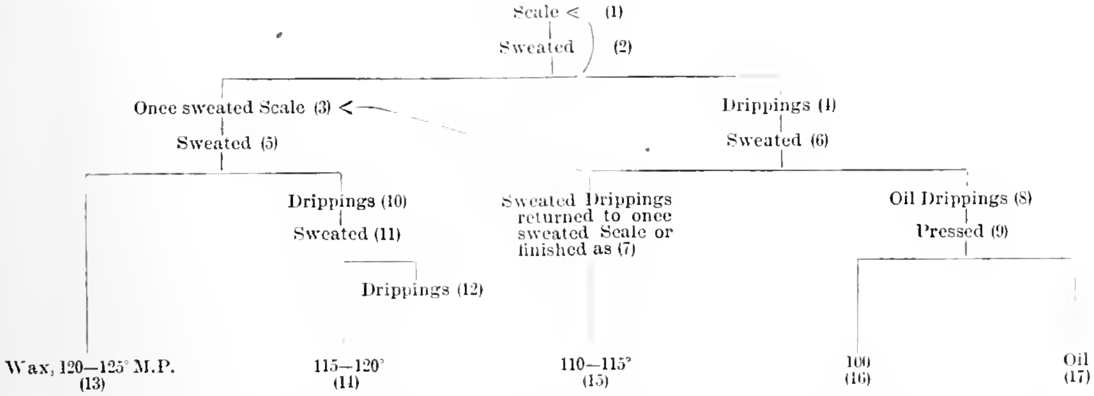
The following diagram gives a rough outline of the several stages of wax refining by the sweating process :—

wood, are placed, and which extend right across the lower openings. It is evident that when pressure is applied by screws or otherwise to the side A which forms the end of the system, the strips of soft wood which go to cover the openings of the cells will rise slightly, while the iron strips which cover the blank spaces between will correspondingly fall.

This arrangement I find is more than sufficient to seal the openings of the coolers. The wood after being sometime in use becomes very pliable, and easily adapts itself to form a perfect covering for the openings.

To empty the coolers it is only necessary to relax the screws *b*, and draw forward the strips of wood, when the cooled paraffin cakes are free to descend into the sweating cells, after which the strips are pushed into their place and the screws tightened, when the cells are again ready to be filled. Another method of sealing the openings is shown at D, but this latter would require to be made very uniform throughout, as any irregularity between the two surfaces would cause leakage.

DIAGRAM B.



It is obvious that when any considerable quantity of material has to be dealt with, the amount of individual handling in the way of filling and emptying the pans, transferring the cakes to the ovens, and taking them out again, must be enormous.

The apparatus which I have ventured to bring before the Section is designed to diminish the amount of labour inseparably connected with the present mode of working.

It is also constructed so that the sweating may be obtained simultaneously from both sides of the paraffin, and which permits of it being done at a much lower temperature and with greater rapidity. Besides, the cakes can be made of much greater thickness than at present, the comparative power being thereby increased. Further, the process can be made continuous by duplicating the cells, vertically, in which the sweating is conducted. This is obtained by taking advantage of the gradual diminution in bulk which the paraffin undergoes in the course of sweating. Although this latter advantage effects no great economy, yet it makes the production of the full proportion of first-class wax obtainable from crude scale by one operation a possibility.

By reference to the rough sketch Fig. 1, it will be seen that the coolers A are set directly above the cells in which the sweating is conducted. The cooling and sweating cells may be made of any convenient size. The size proposed for any single operation might advantageously be 3ft. broad by 6ft. high. The way in which the coolers are sealed at the bottom is made to depend upon the shape in which the alternate strips of soft wood and iron, or soft wood and hard

In order to facilitate the dropping of the cakes from the coolers, a very slight taper is put upon them, which need not be more than $\frac{1}{16}$in. per 12in. in height. The distance between the coolers and the sweating cells is less than the height of the cell. In arranging it thus it gives direction to the cakes of paraffin, as in passing from the coolers to the sweating cell it has entered the latter before leaving the former.

The sweating cell B is constructed of wire netting or perforated sheet metal; inside of which is hung a coarse woven cloth of any description, but preferably of woollen plaiding. On the top of the cell there is set a light iron casting which goes to form the entrance, and assists in keeping it in position. At the bottom there is another casting *c* with an opening the same size as the cell, the edges of which are turned up all round, both in and outside, forming a channel gutter which is provided with an outlet leading to the rhone *d*. The cell is set within this channel, and as the cloth extends to the bottom, the liquid portion which is fused out of the paraffin is conducted to the channel by the capillarity of the cloth. In order to prevent the solid cake from falling through the lower opening, there is provided a sliding door *e* of thin sheet iron, the sides of which are turned down and over-lap the inner sides, covering it like a lid. The passage for the edges of the door is therefore between the inner sides of the gutter and the cloth. This gives direction to the liquid portion, and effectually hinders any part of it from finding an outlet other than to the gutter.

In adapting this apparatus for a continuous or fractionating process, it is necessary to have two or more sweating cells in height, and a proper means of regulating the temperature. All the parts and arrangements remain the same as described, only the doors in the upper cells may, if thought proper, be dispensed with, as the paraffin in its plastic condition moulds itself to the irregularities of the cell, and effectually stops any passage to the one beneath.

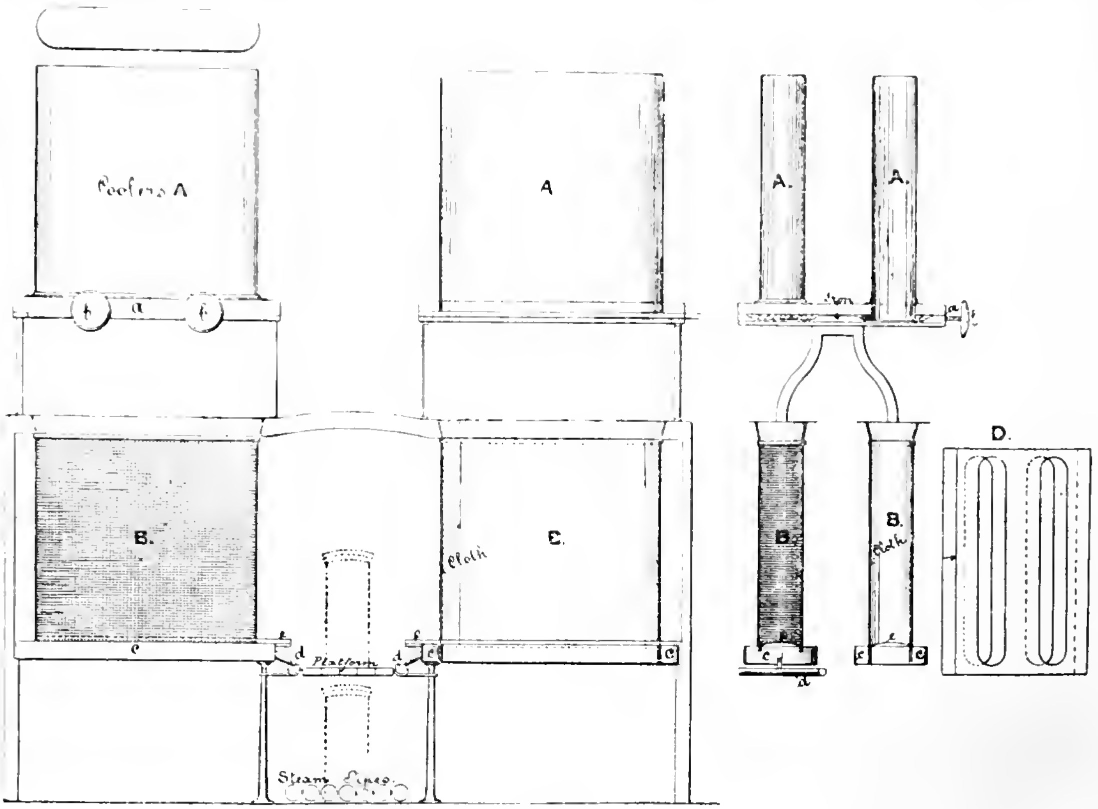


FIG. 1.

Suppose such an arrangement be constructed of three cells as shown (Fig. 2), and that the temperature is under proper control. It is evident that the most and grosser part of the impurities will be drained away in the first or uppermost cell, and that the cake will have correspondingly diminished in bulk before passing to the second or middle cell, where the soft and intermediate soft paraffin would be sweated out. Again, on passing to the third cell, the cake of paraffin will not be more than 65 per cent. of its original bulk, but containing all those hard intermediate fractions which correspond with No. 3 (shown on Diagram B), and which after further sweating and the proper melting point attained may be discharged by withdrawing the bottom door. There is not the slightest danger of the partially-sweated paraffin falling out, as the descent of it is only gradual; indeed, one important feature in this arrangement—either as a simple or complex structure—is that the cake will not come out until it is perfectly sweated, which is only attained at a temperature which if prolonged would result in the complete fusion of the paraffin.

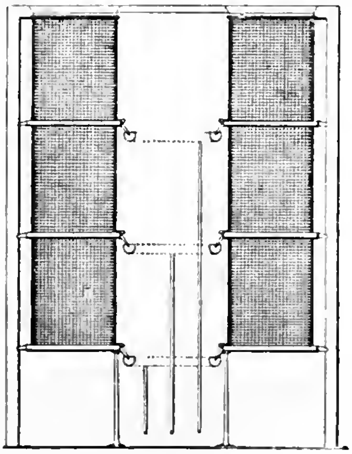

FIG. 2.

In working with an apparatus constructed of three cells, I find it can be charged and discharged every four hours, beginning with a scale of melting point 112—114° F., and finishing with a wax of melting point 126° F. As the drippings are separately fractionated out in three grades of purity, it facilitates their subsequent treatment to have them always of a uniform composition and melting point.

DISCUSSION.

In the absence of Mr. Tervet, it was agreed to postpone the discussion till the next meeting of the Section.

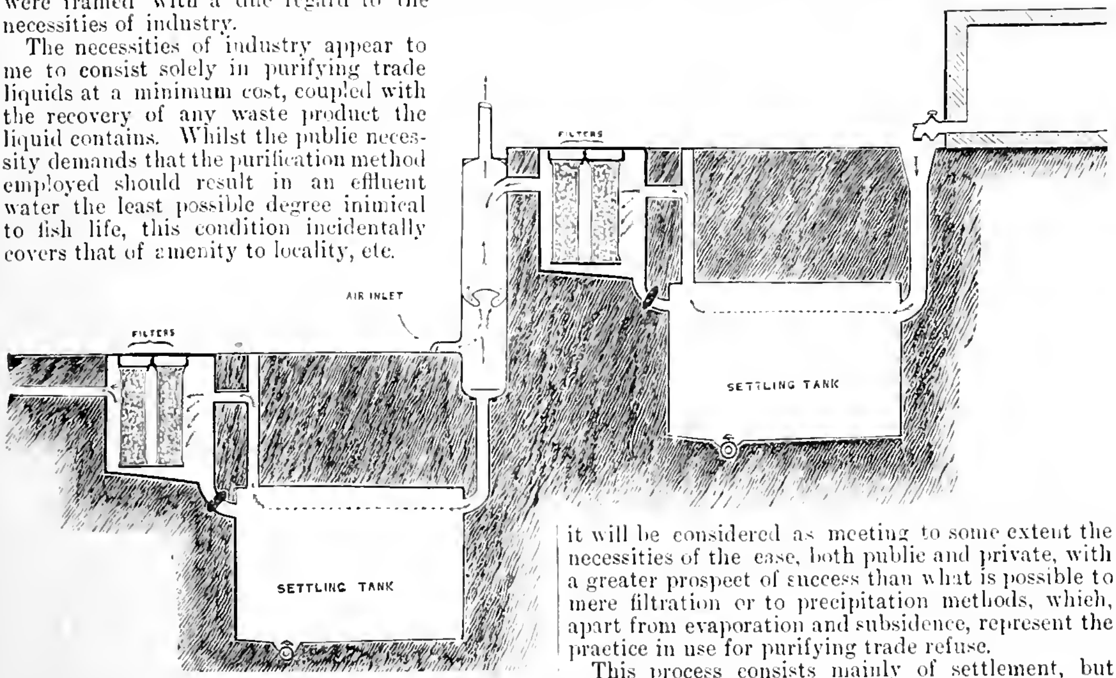
◆

RIVER POLLUTION BY TRADE LIQUIDS.

BY W. H. HARTLAND, C.E.

SIR HENRY ROSCOE, M.P., moving the rejection of Sir Edward Birkbeck's River Purification Bill, in the House of Commons last year, said he desired to point out that whilst the Act of 1876 discriminated between the pollution caused by sewage and that produced by manufactures and mines, no such distinction was drawn by the Bill proposed. Such a distinction was, however, absolutely necessary, for whilst sewage had everywhere an approximate composition, and was, therefore, capable of treatment by similar methods of purification, manufacturing pollution was of the most varied description, as was seen in the case of breweries, alkali works, dye works, etc.; so that not only were the methods which should be employed different, but the standards of purity must also be different. Further on he remarked that science was in a position to deal satisfactorily with sewage at a certain cost, but as regarded manufacturing pollution the same could not be said. The first conclusion of Sir Henry is somewhat open to doubt, but the latter will be generally accepted as correct. In concluding his speech against the Bill, he said, speaking on behalf of manufacturers interested in the question, he desired to say they were in no sense hostile to measures of river purification, provided these measures were framed with a due regard to the necessities of industry.

The necessities of industry appear to me to consist solely in purifying trade liquids at a minimum cost, coupled with the recovery of any waste product the liquid contains. Whilst the public necessity demands that the purification method employed should result in an effluent water the least possible degree inimical to fish life, this condition incidentally covers that of amenity to locality, etc.



I admit that fish life may be possible even in presence of a chemical effluent when diluted by the natural water of the stream into which it discharges; but something more than this is required. You must take into account the "cumulative effect" of sewage or a chemical discharge for long periods. Then, again, other trades on the same stream should be considered, especially those requiring comparatively pure water. A chemical discharge on the upper reaches of a stream is often as unjust to other trades lower down as it is to the public in destroying fish life, etc.

Pollution by trade liquids takes two forms, or that in suspension and solution. We may also divide trade liquids another way, or those which are worthless from those which contain a waste product of more or less value, if we could but succeed in recovering it. For the former class the purification method should be of a simple automatic nature, as the cost of working, however slight it may be, means so much extra cost on the manufacture; but for the more pernicious class of refuse the case is different, and each one must be judged on its merits. But it is almost safe to assume that the more pernicious the liquid the greater the probability it contains an element of value which, if recovered, might be sufficient to repay the cost of purification. It was solely on the grounds that no means were known—except, perhaps, evaporation—whereby this class of liquid could be purified, that led to the rejection of the Rivers Pollution Bills of Mr. Hastings and Sir E. Birkbeck in the last sessions of Parliament.

The process of purification and results of experiments I have to lay before you appear to go a considerable way in the direction required, inasmuch as they seem to meet the case of both classes of liquid, but especially so in the case of all those where the polluting matter is in suspension, whilst in the case of solutions any matter recoverable by the process is recovered in the form in which it exists in the liquid, which admits of its use if possessing a value—or if not, its bulk is reduced to a minimum, and so is the cost of disposal, and as the treatment is purely natural and accords with the public necessity of restoring fish life to our rivers and streams, I shall hope it will be considered as meeting to some extent the necessities of the case, both public and private, with a greater prospect of success than what is possible to mere filtration or to precipitation methods, which, apart from evaporation and subsidence, represent the practice in use for purifying trade refuse.

This process consists mainly of settlement, but under somewhat peculiar conditions, or what I will term equilibric subsidence, under which the full effect of the laws of gravity may be obtained in freeing a liquid from suspended impurity. The apparatus employed is simply a true gravitation siphon, consisting of two parts—the first a catchpit or settling tank, whilst the second part serves the purpose of a "wash-out" or flushing tank for the catchpit when the sediment is removed; and by means of two vertical lines of filtering obstruction, which serve to convert the tank into a siphon as well, it throws back on the catchpit an equal pressure, which prevents channelling, and produces an "equilibric line" level with the lower end of the siphon necks or the inlet and outlet. Below this line the water is still, and allows of the collection of matter to take place continuously until it reaches the practically "inert water" passing above.

Whenever the sediment is removed from the catchpit, the effluent water standing in the "high-level tank" may be precipitated into the catchpit, the opposite end being flushed by admitting a sufficient quantity of liquid by the inlet. Both these operations are performed by simply moving a couple of valves. The catchpit siphon is in duplicate, so that when one becomes full of sludge the stream of sewage is diverted through the other; that full, being cut off from the wash-out tank, which serves the same purpose for both.

The degree of subsidence necessary to suit the different circumstances of the various liquids is quite under control, being regulated by the velocity of the liquid passing through, and by the counteracting influence of the filters on the hydrostatic head or pressure of inflowing water; but in any case this process of settling succeeds in the automatic division and collection of two separate sediments of different degrees of sp. gr. from any liquid exposed to its influence. This feature of separating the matters contained in a liquid is important, and within it, perhaps, we may find the solution of the problem of utilising the products of either sewage or trade liquids, as it enables us to use that which is useful and reject that which is not.

The filters of the wash-out tank, of course, may be either neutral or neutralising as required. They also serve to arrest all floating matter, and admit of the purified effluent being discharged at about the same level at which the raw sewage enters the catchpit part of the siphon. This is also a feature of importance in preventing impoundage where this occurs, and also by reducing to a minimum the cost of pumping to avoid its influence. These features will, I hope, be considered as steps in the right direction.

In support of this view, I may just draw your attention to the local case at Crosshill, where a similar contrivance was constructed to carry the sewage across the railway cutting. The contrivance, although an unequal-sided siphon, I believe, quite refuses to pass matter heavier than the water in which it is carried. The first siphon, or the catchpit and wash-out combined, is simply the Crosshill siphon carried out to its logical conclusion, and would possibly prove sufficient for the recovery of all descriptions of suspended matter from trade liquid.

For dealing with the more serious class of liquids or matter in solution, I propose a double siphon, coupled with the process of aëration between the two. Experiments on various liquids tend to show that, after the heavy suspended matter has been removed, the fine organic matter, which is not amenable to either subsidence or filtration, or the process of the first siphon, is usually developed by aëration sufficient to cause it to subside in the second catchpit or wash-out. I am aware that this effect is somewhat opposed to the generally accepted idea of the "effect of the process." I may also point to the general idea regarding subsidence. Most persons, if asked to define perfect subsidence, would at once say perfect rest in a subsidence tank. The law also accepts this idea as to perfect settling. Still, I beg to take exception to the view, and you will be able to form an opinion from the results of experiments.

But on the question of Aëration v. Oxidation, I may say a few words. You are aware, no doubt, that the Metropolitan Board of Works contemplate a very large outlay and annual cost to chemically treat the London sewage. The treatment proposed is in general opposition to precipitation methods, being mainly devised for oxidation.

Mr. W. J. Dibdin, F.C.S., etc., the principal chemist to the Board, and author of the treatment proposed, read a paper recently to the Institute of Civil Engineers. In explaining his reasons for using so small a quantity of chemical as 1 grain sulphate of iron and 4 or 5 grains of lime per gallon of sewage, he said the matters in an actual "putrescent state" were the only ones which required immediate destruction, and these were insignificant compared with the "total organic" matter present. Consequently, the quantity of chemical required was but a fraction of what would be necessary for its complete destruction.

He then went on to say that aëration had recently been put forward under the title of oxidation. This was "a misnomer." True, the ultimate object was oxidation, but if the idea was to be retained that a very partial aëration of a strongly alkaline effluent was "equivalent" to complete aëration of a neutral effluent free from actual putrescent matter, a powerful blow would be struck at the system, which, when properly carried out, was incontestably one of the utmost importance.

These remarks, by so distinguished an expert, tend to show, in my humble opinion, that a real inquiry into the true function of the natural process would prove of great advantage. So far as my experiments go, the effect of aëration is dependent on the process adopted before and after its application. I confess I do not understand Mr. Dibdin's remarks, as, in the first place, there is no "strongly alkaline" effluent to aërate outside trade liquids, except from a chemically treated sewage, and if this can be sufficiently oxidised within financial limits, why should it be aërated? whilst, if the ultimate object of aëration is oxidation, why chemically treat the sewage at all? Because it requires no technical skill to understand that a "naturally" oxidised effluent is, at the worst, perhaps a dirty but practically harmless water, and, therefore, not inimical to fish life, whilst the same cannot be said of any description of artificially produced effluent.

The experiments carried out prove that under certain conditions the effect of aëration is entirely opposite to the destroying effect attributed to artificial oxidation, it being, in fact, an almost purely developing effect, both as regards sewage and the various descriptions of trade liquids on which experiments have been made.

In giving the results of these, I have selected a few as being representative of the worst class of pollution from trade refuse. The results are from practical experiments on quantities of either 3 or 5 gallons, the apparatus employed being about double the size of drawing. The weights per gallon are for dry matter, except in two cases to be mentioned, and are exclusive of matter lost in the filtrates; whilst those for soluble matter represent about 70 per cent. only of the quantity actually recoverable, as nearly one-third of sample is left in the first siphon. The weights are the result of evaporating the sediment collected in the catchpits only.

EXPERIMENTS.

First is an acid solution, containing salts of iron. The filter media in this case was simply lumps of natural chalk. The recovery of matter reckoned as a thick paste was—

Before oxidation	120	grains
After ,, ...	160	,,
Or a total of	280	,, per gallon.

The next is a solution containing soluble salts of potassa. The matter recoverable by perfect rest for 24 hours was 144 grains, reckoned as a paste about the consistency of tar, whilst the recovery under equilibric subsidence was 292 grains; whilst after oxidation it gave up a further quantity of 219 grains; and on repeating the process of oxidation and settling, it gave a further quantity of 233 grains, or a total of 744 grains per gallon.

The next experiment is on the putrescent liquid from a tannery and skin works. One sample gave up 547 grains before and 146 grains after oxidation. Another gave 583 grains per gallon by equilibric settlement alone. These liquids combined are settled in the ordinary way, the effluent being afterwards treated with alumina. The sludge from both processes is filter-pressed, resulting in about 470 grains of sludge cake. Even if this is reckoned as dry matter, the loss in the effluent is probably two-thirds of the whole matter actually present in the liquid, though it is doubtless bleached by the chemical treatment, and not apparent to the eye.

The next are dyes. The chemical Turkey-red gave 39 grains before and 21 grains after aëration, or a total of 60 grains per gallon. The yellow dye give by equilibric settlement alone, 65 grains per gallon; whilst the original Turkey-red dyes gave 47 grains before and 20 grains after aëration, or a total of 67 grains per gallon. This matter, I understand, is principally boiled blood.

The last is the dreg or pot ale from distilling. This gives 55 grains per gallon after having settled in the ordinary way for several days. Oxidation in this case does not develop much matter (10 grains per gallon), but what little is recovered is peculiarly nasty; the same may be said of the gas. I should just remark that when the whole process is employed, in addition to recovery of four different solid products, we may also obtain the gas which is ejected in the process of aëration. Aëration also recovers oil in solution in the last siphon. I think I may say all the products mentioned are practically new, and samples are here for inspection. I may also suggest that the four products which may be recovered from sewage seem to offer grounds for believing that a financially valuable product may possibly be recovered from this source at last, in place of the ordinary sludge as at present.

DISCUSSION.

Mr. Christie considered that the nation would be indebted to Mr. Hartland if his process could accomplish all that had been said of it. The difficulties he had to speak of were in reference to dye works in the neighbourhood of the Leven, where a great deal had been done to grapple with the waste discharge from dye works. The chief difficulty was in the soapy solutions holding a small quantity of free oil in suspension. Mr. Hartland had spoken of 400 grains down to 60 grains per gallon, if he had followed him properly; but in the Leven the waste products leaving the works were much more dilute, and only carried from 5 to 15 grains per gallon. The works for the purpose of dealing with the discharged liquids were unfortunately situated on a very low level, so that any method for treatment must follow the pumping to a height of from 10 to 20 feet of the liquids discharged from the dye-houses, and when it was considered that in his own works four million gallons of these refuse liquors were discharged per day, it was evident the treatment with either acid or salts of lime or magnesia must necessarily involve great outlay by reason of the dilution of the material discharged. A great deal had been done at his works in the way of chemical treatment, but so far it had failed to deal successfully with the enormous quantity of liquid discharged into the river. Within the past year his attention had been turned to subsidence, and he agreed with Mr. Hartland that the subsiding system seemed to indicate that more successful results might follow from that method of treatment, if a chemical could be found suitable for the precipitation of the soapy liquors and fats in a fine state of division—that should as far as possible increase the specific gravity of the resulting compound in order to facilitate the subsidence, as the difficulties are accentuated from the fact that the fats have a specific gravity less than water; and as the refuse liquids contain say, on an average, 10 grains per gallon, the precipitant put into this enormous volume of liquor effected precipitation rather slowly, and in such a fine state of division, that great difficulty is experienced in getting it to subside, and the success of the process must naturally depend on the effectual subsidence of this compound, with a specific gravity as far as possible above that of water. The method of aëration would have, he was afraid, no effect upon the soapy liquors. The colour discharged with the soap was not capable of being acted upon by aëration so far as his experience went.

Mr. Tatlock asked how long it would take to treat a large quantity of liquid in the manner described?

Mr. Hartland replied that for a large body of liquid a number of apparatus would be required, but with the apparatus described 10,000 gallons per day could be dealt with automatically. The apparatus was only 21 feet long by 6½ feet broad in its broadest part; in practice each apparatus would extract from the main body of liquid a certain quota, according to its capacity, so that quantity of liquid was immaterial. For instance, a stream of sewage of 100,000 gallons per day could either be treated by one apparatus of 100,000 gallons capacity, or by two of 50,000 gallons, or by 10 of 10,000 gallons per day capacity.

Mr. Liversedge asked what kind of filtering medium was employed?

Mr. Hartland replied that broken bricks or raw chalk might be employed, but in the case in question common ashes were used, which were very rough in the first two filters, and finer in the last two.

Mr. Cuthbertson inquired if the process was applicable on a much larger scale?

Mr. Hartland replied that on a larger scale it would necessarily be much better, because the deeper one went the better the law which governed the system was brought into operation.

Mr. Tatlock believed that experiments on a somewhat extensive scale had been made by the Corporation of Glasgow with regard to the effect of aëration on the town sewage. The apparatus employed was one of the most perfect forms of oxidisers known, and consisted of a screw revolving vertically at a high rate of speed in the cylinder containing the sewage matter, by which the air was beaten down into the liquid and, so to speak, "atomised." The appearance of the liquid under aëration was that of milk, arising from the air being churned up with it, and the effect in that case was not very encouraging, so much so that the process was not adopted. It was found that after settling the solid matter from sewage and treating it in as clear a state as it could be got, it began, after some time, to smell again, and hence if it were applied to sewage matter before being discharged into the river Clyde, by the time the purified or aërated sewage had been carried up and down several times by the flow of the river and backwash of the tide, the smell would begin again. Oxidation by that means was also found to be rather expensive, and from some experience he had had he believed he was justified in saying so. He was quite pleased with the description given of the apparatus, but he thought that as far as aëration was concerned it had hitherto not been found successful for treating sewage, although further experiments in that direction were very desirable.

Mr. A. J. Liversedge believed that no question could exist as to the extreme importance of the subject. As far as he could understand the process, from the description given, it was simply a precipitation process combined with filtration and aëration. The sewage was in the first place allowed to settle in a large tank, but Mr. Hartland would not claim any originality as to that, as it was the first step taken by anyone who attempted to deal with sewage or similar substances. Afterwards, the partially cleared sewage (which was not even free from the whole matter in suspension) was to be passed through a filter, and that also had been tried on a large scale in several places, though, as far as he knew, the only filtering process which had been found valuable was simply to allow the sewage to be passed through land. All other filtering processes, whether tried on crude sewage or partially cleared sewage, appeared to have failed, owing to the filtering mediums having become rapidly choked up and useless, and to the trouble and cost of cleansing and renewing them. Experiments on a large scale had been tried at Crossness to filter sewage sludge through filter-presses, but it was found in that case absolutely impossible to filter the sewage without first treating it chemically, as otherwise the cloth used became quite slimy and useless in the course of a very short time. Referring to Mr. Hartland's precipitation tank, the settled matter in that tank would contain at least 75 per cent. of water. Mr. Hartland dissented from that, but in that tank he had simply the action of gravity, and even when you employed great pressure in order to separate the liquids from the solids of sewage, the substance obtained contained from 50 to 60 per cent. of liquid; and he would like to ask what would be done with this sludge from the tank? Mr. Hartland had not explained in detail the apparatus he proposed for forcing air amongst the sewage for his final process, nor given the quantity of air required to effect the necessary aeration or the cost of the apparatus for that purpose. He was convinced that if Mr. Hartland would work out the cost of treating sewage in any district by his apparatus, he would be greatly surprised at the amount of money it would come to. He would instance the experiments made by the Metropolitan Board of Works, who had tried probably every method that had been suggested that contained any promise of success, and whilst many methods had been proposed and had given fair results on a small scale, it was found that when they came to be multiplied, and to deal with 80 or 100 million gallons per day, the cost became so enormous as to put them out of the question. It was not merely a question in the case of sewage of separating the solid matters from the sewage, but what was Mr. Hartland going to do with the recovered sludge obtained in his precipitation tank—which must contain a large amount of water,—especially seeing that he did not advocate chemical treatment? That was a most important question; but there were many other points in connection with the process Mr. Hartland had sketched—for example, the nature of the filtering medium, the method of cleansing, the cost of renewing, the details of the final aëration, the length of time necessary to obtain a particular result, the cost for treating any given quantity of average sewage, and so on—upon which further information was desirable.

Mr. Hartland pointed out that his paper dealt with trade liquids, whereas the discussion had veered into a question of sewage, which was a totally different thing from trade liquids. In the first tank proposed, there could be got what was dredged up from the bed of the Clyde, and it could be dealt with in exactly the same way; but supposing this system was in operation in Glasgow, the sludge might just as easily be sent down by the barges, but instead of dredging it out of the bed of the river it could be dredged out of the tank in question. The system applied to sewage aimed at recovering a product of some value, the tanks being designed so as to separate by gravity the constituents of sewage into three different forms of deposit, so that they might use what was good and reject that which was not, meaning the ordinary sludge. He placed no value on this material; indeed, if it entered the manure at all, it would first be burnt to an ash. He might, however, remark, that if they burned the small quantity of coarse sludge there is by this system compared with others, then the two important sanitary features of pumping (water in this case) to obviate impoundage by tidal or other influence, as well as the forced ventilation of sewers, become feasible and easy operations, whilst he submitted the destruction of sludge was the only permanent mode of disposal, and which sooner or later must be adopted.

Erratum.—Mr. Tatlock's paper, "On the Determination of Minute Proportions of Iron, with Special Reference to Alum and Sulphate of Alumina," April number, p. 279, third line from conclusion of article, *for* "0·00004grm." *read* "0·00001grm."

A LECTURE ON FLAME.*

BY LEWIS T. WRIGHT.

I want to call your attention particularly to the fact that sometimes flame travels rapidly and sometimes slowly. This subject is one of some importance, and is what we call the velocity of propagation of flame. We can prepare, with coal-gas, mixtures having flames that travel at from 6ft. to 1ft. per second. And I want you to distinguish between the quiet, uniform, and slow propagation of flame that takes place in the first half of this 13ft. glass tube, which is measurable to the eye, and the extremely rapid and detonating explosion sometimes taking place in the second half of the tube. The first I will call an explosion of the first order, the second, infinitely more rapid, I will call an explosion of the second order. Let us suppose I have an explosion of the first order taking place in this tube that does not exceed the velocity of 4¼ft. per second. I can arrest it—put it out by inserting a small piece of metal gauze in the tube. We learn then that when the flame is travelling at a speed of less than 4¼ft. per second the gauze will arrest its passage. I will now endeavour to prepare a more explosive mixture, having a velocity of propagation of flame of more than 4¼ft. per second, and you will, perhaps, find the flame penetrating the gauze as though it were not there. We have learnt a very important fact. I want to show you, if I can, in a more marked manner how an explosion of the first order becomes connected with one of the second and more terrible kind. Here we have a mixture, the flame of which lodges in the tube, and is not, as at first, a very thin surface of flame, but occupies, perhaps, ½ an inch of the length

---

* This lecture, of a semi-popular character, was delivered on the 18th March, by invitation of the Nottingham Section of the Society. The extract given contains an account of important original investigations described by the Lecturer.

of the tube. This flame is in a violent state of oscillation. When its tremor is sufficiently violent, explosion of the second order will be initiated. There are two points here to observe: that a definite explosive mixture may have a velocity of propagation of flame when it is undergoing explosion of the first order, that is, as low as 1¼ft. per second, but when it becomes sufficiently agitated to give an explosion of the second order the rate of propagation of flame is several thousand feet per second.

The following table sets forth the particulars of the experiments made in a glass tube 13ft. long and 0·75 inch in diameter:—

Mixture.		Lineal velocity of efflux of Mixture.	Rate at which Explosion of first order travels in tube.	Total velocity of propagation of Flame.
Gas.	Air.	Feet per second.	Feet per second.	Feet per second.
10·3	89·7	1·21	1·1	2·31
12·2	87·8	1·21	2·0	3·21
15·0	85·0	1·28	3·0	4·28
17·7	82·3	1·32	4·8	6·12
19·6	80·4	1·35	3·0	4·35
21·2	78·8	1·38	2·1	3·78
22·1	77·9	1·39	1·3	2·69
23·0	77·0	1·41	Stationary.	—

In thinking of explosive mixture you must bear in mind the difference due to the mixture and the difference due to the class of explosion. Some years ago I was connected with a large gasworks, and there we had a great number of safety lamps, as there were innumerable places where it would have been fatal to enter with a naked light. The lamps were in the charge of a most competent man, and were carefully examined and tested before being sent out for use on the works. Well, one morning before daybreak a larger purifier exploded just as the men were going to work on it. One man, who was carrying a safety-lamp, was knocked down, and others were burned. The lamp in its fall had its gauze injured. The explosion was looked upon as most mysterious, and some thought that the hole in the gauze had not been caused by the fall of the lamp on a sharp piece of iron, but had been there when it left the lamp-room. It was an unpleasant occurrence, that never became satisfactorily cleared up. Amongst experienced men there had always been a feeling of distrust regarding these lamps in circumstances where there was known to be much gas about, and an old hand might be known by his habit of leaving his lamp outside if called upon to enter any building in the dark where gas was escaping. Some time after a similar explosion occurred by a young man placing a safety-lamp near a current of gas which ignited, burning him severely. The lamp was rigorously examined, but no defect could be found in it, and it stood the test well. I may say that the test was really inefficient. I determined to thrash the matter out, and trying the lamps by various methods at last found out a means of blowing them all up. Not one could resist the new test, which was simply this: By creating an explosion inside the lamp, by a sudden application of the explosive mixture to it, the flame was passed through the gauze, igniting the mixture outside. This was a serious revelation, and exposed the deficiencies of the old test for soundness, which was, that the lamp should be put out by being smothered with gas. I am going to show this experiment in an exaggerated manner. Here we have a hollow tin vessel covered on the top with gauze. I am going to create an explosion inside it, and I hope you will be able to see the flame as it passes through the gauze. That the flame is projected some distance, I will prove by causing it to light an unignited stream of gas at a distance of 4 feet. I found out that the Davy lamp gauze would not always resist the passage of the flame resulting from a small explosion in the lamp. Of course now a-days we know much more of the Davy lamp than we did, and the ordinary forms are not considered safe in what we might call moderate currents. In a current of gas about 4 or 5 feet per second the flame is blown through the gauze. This is well known I believe now, but I do not think the circumstances of an explosion inside the lamp blowing the flame through is so well known. It is evident, then, that when the rapidity with which the flame is moving exceeds a certain rate it is blown through the gauze. When I discovered that an explosion inside the safety-lamp was sufficient, with coal gas at least, to pass through the gauze, I felt I had made an unpleasant discovery, and thought that perhaps there was something wrong with the material. I tried all sorts of makes of various meshes. There was nothing to choose between them. It was no use having finer mesh, for this reason: as you reduced the size of the apertures you reduced the thickness of the wire and its weight, so it was as broad as it was long. Still flame will not touch a cold metal surface. If I hold this flame against this metal plate, there is a space between that is not flame. You will see that, as flame to be flame must be hot, it cannot touch this cold metal, because the metal will cool it below the temperature at which this gas can give the phenomena of flame. Often, in these tubes, I find if I let the flame go slowly up to the gauze that it is extinguished before it quite touches it. When the flame is travelling in the direction of the gauze, the question whether it will pass or be extinguished is simply a question of the rate at which the flame is travelling, and the rate at which the gauze is cooling—a battle between the velocity of propagation of flame and the rate of cooling that the gauze can exert, which will be decided in favour of the most powerful. Davy lamp gauze is made by interlacing about twenty-eight wires of $\frac{14}{1000}$ths of an inch diameter, forming the warp over and under twenty-eight wires of woof of same diameter, and the result is a number of square apertures slightly larger than the thickness of the wire, being about $\frac{21}{1000}$ths of an inch across. Two adjacent wires of warp are separated from each other by a little more than the thickness of the wire forming the woof, and *vice versa*, because the wires of the woof bend under and over the wires of the warp, just as the wires forming the warp bend under and over the wires of the woof—so you see if, with this system of weaving, we wish to obtain smaller apertures, we must employ thinner and lighter wires, having less cooling power. However, let us suppose that the wires of the woof are very strong, and will not bend at all; the wires of the warp only bend under and over the straight woof wires. Then you see that the warp wires can touch each other, and you get rid of the square apertures. We can also get, by employing very stiff wires one way, and very thick, soft wires the other, a heavy gauze, with no direct openings, but small, tortuous ones. We can do what we could not do with the other mode of weaving—viz., procure extra weight of metal, at the same time reducing the apertures. This method of weaving is called basket-work, because baskets are made like that.

By taking off the old Davy lamp gauze from our lamps, and replacing it with the heavier basket-work, I secured lamps that would stand any test I could apply, and I had gas from a compressing engine, at a pressure of 20lb. and more on the square inch, blown on them, and they did not fire. My object of procuring a safe lamp was satisfied, and I may say that attempts to make the lamp safe by using two or three instead of one layer of the ordinary Davy lamp gauze were not successful.

Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

An Improved Filter for the Purification of Water and other Liquids. P. Hikely and J. Radcliffe, Rochdale. Eng. Pat. 4623, April 2, 1886. 6d.

The improved filter consists of a cylindrical or other shaped vessel provided with an upper part for the admission of water and a lower part for the outlet. Between the two is the filtering body secured in a slide fitting into two grooves in the body of the filter; the cover of the slide is held in position by a cross bar and centre screw.—C. C. H.

Improvements in Filters. C. E. Gittins, London. Eng. Pat. 5343, April 16, 1886. 8d.

Two bowls or dish-like cylindrical bodies are screwed together with the filtering media between them; this consists of charcoal, porous earthenware, or sandstone. —C. C. H.

Improvements in Filtering Apparatus. C. W. Rabitz, Hamburg. Eng. Pat. 5669, April 24, 1886. 6d.

A number of perforated hollow drums covered with felt are strung upon a hollow shaft capable of rotation; the shaft carries a number of brushes the ends of which rest on the filtering drums. The whole is enclosed in a tight vessel into which the unfiltered material is forced. The filtrate escapes from the apparatus by the hollow shaft. The residue is removed from the surfaces of the filtering drums by the rotation of the brushes.—C. C. H.

Improvements in Filter-presses for use under High Pressures. H. E. Newton, London. From A. L. G. Dehne, Halle-on-the-Saal, Prussia. Eng. Pat. 6628, May 17, 1886. 8d.

The improvements specified consist in the use of a U-shaped packing ring of leather or rubber placed in a groove between the joints of the plates or chambers. The patentee also claims as novel the use of a finely-grooved filter-plate covered with gauze or sheets of perforated metal for the support of the cloths.—C. C. H.

Improvements in Filter-presses and the Mode of Charging the Same. E. Jones and A. Beech, Tunstall. Eng. Pat. 9759, July 29, 1886. 8d.

In the old form of wooden filter-press the chambers are much weakened by the passage of the inlet nozzle through the strengthening strip on the edges of the chambers. The present invention obviates this by using a cranked instead of a straight nozzle, which avoids the cutting away of the strengthening strip. —C. C. H.

Improvements in Boiler-cleaning Compounds. A. J. Boult, London. From S. W. Merryman, Baltimore, U.S.A. Eng. Pat. 1582, Feb. 1, 1887. 4d.

The new composition consists of tannin, ½lb.; terra japonica, 1lb.; West Virginia oil, 1 gallon; and soda ash, 90lb. The terra japonica is dissolved in water, the oil added, and the mixture passed over the soda ash; the tannin is finally added.—C. C. H.

Improvements in Funnels. A. Gersdorf, Washington, U.S.A. Eng. Pat. 1970, Feb. 8, 1887. 6d.

The shank of the funnel is made triangular in section, to permit the escape of air from the bottle in which the filtrate is received. The upper edge of the body is turned inwards to prevent splashing when the liquid to be filtered is poured hastily into the interior of the funnel.—C. C. H.

II.—FUEL, GAS, AND LIGHT.

Improvements in Coke Ovens. T. F. V. C. Otto and Dr. C. Otto & Co., Dalhausen, Germany. Eng. Pat. 5522, April 21, 1886. 11d.

According to this invention the gases evolved from the ordinary Beehive oven, after being scrubbed for the recovery of the by-products, are brought back and burned underneath the oven. The air required for the combustion is heated by a regenerator arrangement, the waste heat from the burning gases being utilised for this purpose. Drawings are given with the specification. —A. R. D.

An Improved Method of Manufacturing Gas from Benzoline or other similar suitable Oil, and in Apparatus employed therein. T. Drake, Huddersfield. Eng. Pat. 7733, June 9, 1886. 8d.

Atmospheric air, dried and heated, is driven by a Root's blower through benzoline contained in a tank. The air current is distributed by being made to pass through a number of canvas diaphragms placed horizontally in the liquid. As the resulting gas is very explosive, the gas pipes must be provided with wire-gauze checks on the same principle as the Davy lamp. —A. R. D.

Improvements in and Apparatus for obtaining Gas for Illuminating, Heating, and other Purposes. H. Williams, Stockport. Eng. Pat. 8895, July 7, 1886. 11d.

The inventor generates hydrogen gas from fragments of zinc or iron and dilute sulphuric acid in an apparatus similar in principle to that commonly employed in the laboratory for the same purpose. It consists of a tank to contain the dilute acid, and an inverted vessel standing gasometer-wise within this. The inverted vessel carries within it a tray on which is placed the zinc or iron, and is provided in its upper portion with an outlet for the gas. It is supported by a cord or chain passing over pulleys and carrying equivalent weights at the other end. This arrangement is to secure a uniform pressure of gas. The gas may be carburetted by passing through a chamber wherein strips of absorbent material are hung in such a manner that the course is rendered as tortuous as possible. The lower edges of the strips dip into the carburetting liquid, which is maintained at a constant level by means of a ball tap.—A. R. D.

Improvements in the Removal of Ammonia from Coal Gas, and in the Manufacture of Ammoniacal Salts therefrom, and in Apparatus employed in such Process. J. Hepworth and E. Marriott, Carlisle. Eng. Pat. 5858, April 30, 1886. 11d.

The object of this invention is the recovery of ammonia from coal gas, without the use of lime, stills and saturators. Instead of water for washing the gas, a neutral solution of any suitable salt of ammonia is introduced

---

* Any of these specifications may be obtained by post, by remitting the cost price, *plus* postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.........	½d.
Above 8d., and not exceeding 1s. 6d...	1d.
" 1s. 6d., " " 2s. 4d...	1½d.
" 2s. 4d., " " 3s. 4d...	2d.

into the scrubber, whereby the ammonia is absorbed. This solution, thus charged with an excess of ammonia, is neutralised and then again used as absorbing agent in the scrubber, until its density rises to about 40° Tw., when it is evaporated in the usual manner. The gases liberated during the neutralising process are carried forward into a purifier of usual construction. In the annexed drawings (Figs. 1 and 2), *a* represents the scrubber, and *b* the pipe leading to the purifier *c*. The latter contains separate boxes or neutralisers *d*, where the liquor from the scrubber meets a regulated supply of acid from the tank *g*, the gases evolved passing through the pipe *i* into the purifier *k*. The neutralised liquor can be pumped up through the pipe *e*, and sprinkled in the tops of the scrubbers *a* to absorb more ammonia and be neutralised as before. If more ammoniacal liquor is produced than can be treated in this apparatus, an additional closed vessel *m* is used, fitted with a perforated bottom, below which leads a pipe *n* from the scrubber outlet. The vessel is filled with ammoniacal liquor, and heated by a steam coil *o*, and the gas bubbling through it, extracts the ammonia absorbed in the liquor and acts likewise as a carrier to convey the gas to the scrubber inlet through the pipe *p*.—S. H.

FIG. 1.

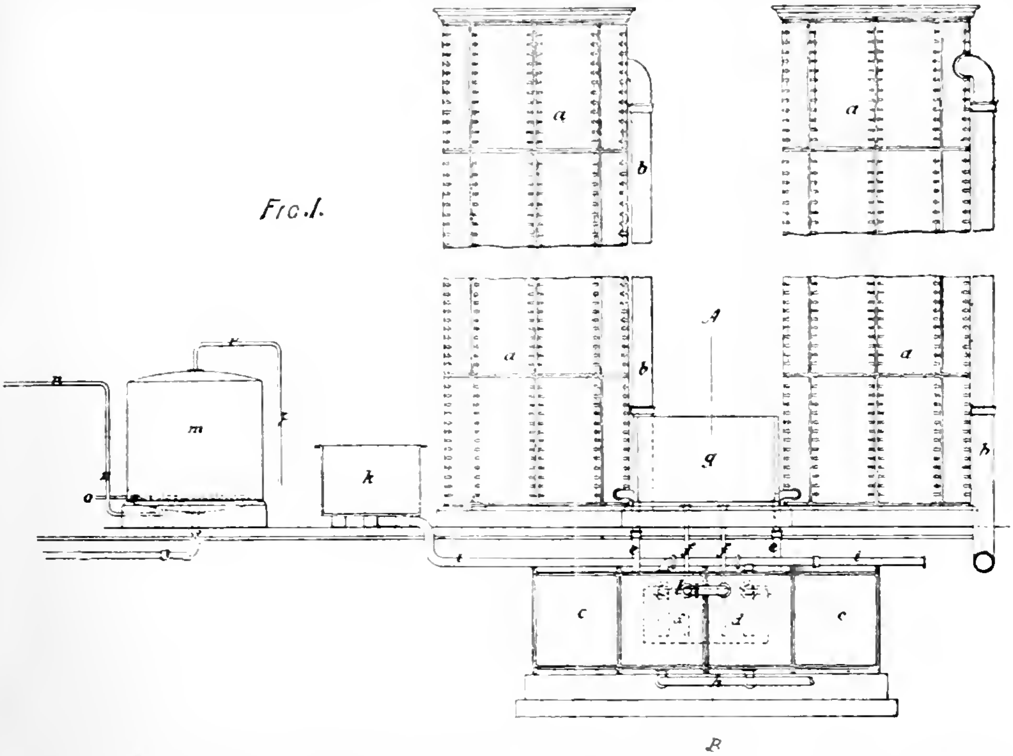

Fig. 2.

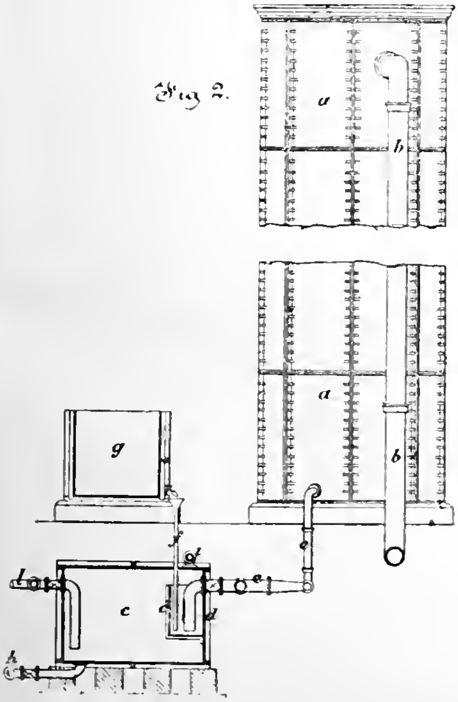


Improvements relating to the Treatment of Gas Carbon, and to the Manufacture of Articles therefrom. F. H. Snyder, Jersey, U.S.A. Eng. Pat. Feb. 1, 1887. 8d.

GAS CARBON is finely pulverised and washed, to remove soluble salts. It is then separated into the qualities represented by the densities of the different particles, either by elutriation, or, in the dry state, by an air blast. The product is available for most purposes where heat-resisting qualities are advantageous—such as safe linings, crucible linings, paint, etc., etc. The dry material is mixed with coal tar or other suitable cementing liquid, to facilitate the moulding. The tar is afterwards removed by baking.—A. R. D.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Lutidines of Coal Tar. G. Lunge and J. Rosenberg. Ber. **20**, 127—137.

THE sulphuric acid, after being used for purifying tar oils, contains a considerable amount of bases and sulphonic acids of hydrocarbons. It was diluted with three or four times the volume of water, left for several days and filtered. The filtrate was evaporated, saturated with sodium hydrate, and the resultant dark oil separated, and distilled with steam. The oily distillate was then dried over caustic potash. Twenty litres of sulphuric acid gave 800grms.

of purified bases. The latter were then subjected to fractional distillation. The fraction boiling between 141—144 yielded by precipitation with mercuric chloride (Ladenburg and Roth's method, this Journal, **4**, 394) lutidine mercurio-chloride, from which the pure base was separated by treatment with potassium hydroxide and distillation with steam. The fraction boiling at 153—156 gave by precipitation with mercuric chloride and isolation of the base a colourless liquid boiling at 156—157°, which was found to be α γ-lutidine. This was oxidised with potassium permanganate, α-lutidinic acid being obtained. This acid, although identical with Ladenburg's and Roth's lutidinic acid, differs in physical properties. It forms colourless microscopic crystals melting at 223°, and gives a blood-red colouration with ferrous sulphate, whilst the acid isolated from animal oil crystallised in lustrous scales melting at 235°, and yielding a reddish-yellow colour with ferrous salts. When the fraction boiling at 156—170° was oxidised with potassium permanganate, α-lutidinic and isocinchomeronic acids were obtained. The formation of the latter acid points to the presence of α-β-lutidine in the mixed bases.—D. B.

Ortho- and Parachlorodimethylaniline. T. Heidlberg. Ber. **20**, 149—151.

Orthochlorodimethylaniline—$C_6H_4Cl.N(CH_3)_2$, is obtained by heating the hydrobromide of orthochloraniline with rather more than two molecules of methyl alcohol in sealed tubes at 145°. It forms a colourless liquid base boiling at 206°—207°. The hydrochloride crystallises in white hygroscopic needles. The platino chloride forms lustrous yellow prisms. The nitroso-compound crystallises from alcohol in yellow needles which are readily decomposed. It is a very feeble base.

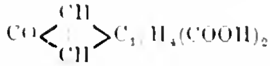
Parachlorodimethylaniline was prepared according to Sandmeyer's method by sustituting chlorine for the amido group in paramidodimethylaniline. It crystallises in large, lustrous, flat needles soluble in alcohol, benzene and ether, and insoluble in water. It melts at 35·5° and boils at 230°—231°. The hydrochloride forms a difficultly crystallisable syrupy mass; the platino chloride $[C_6H_4Cl.N(CH_3)_2]H_2PtCl_6$ crystallises in gold coloured prisms and the nitroso compound forms splendid orange yellow needles melting at 56°. It is soluble in alcohol, ether, benzene and petroleum spirit.—D. B.

Action of Sulphurous Anhydride on Benzene. C. E. Colby and C. S. M'Loughlin. Ber. **20**, 195—198.

ON heating a mixture of benzene (100grms.) and aluminium chloride (35grms.) on a water bath, and introducing sulphurous anhydride until absorption of the latter is complete *diphenylsulphoxide* $C_6H_5SO.C_6H_5$ is obtained, which crystallises from xylene in small transparent yellow crystals melting at 70—71°, belonging to the triclinic system. It is readily soluble in alcohol, ether, glacial acetic acid and benzene, sparingly soluble in cold petroleum spirit. When oxidised with potassium permanganate diphenylsulphone is obtained. It forms crystalline laminæ, melting at 128°. When reduced with sodium, diphenylsulphide melting at 272° is obtained. Diphenylsulphoxide may also be prepared by the action of thionylchloride on benzene in the presence of aluminium chloride. When equivalent quantities of diphenylsulphoxide and sodium nitrate are dissolved in concentrated sulphuric acid, and the two solutions mixed and heated at 100° for two hours, a product is obtained which can be fractionated by crystallisation into the following nitro compounds:—(1) Yellow crystals sparingly soluble in alcohol, readily soluble in glacial acetic acid, melting at 163° apparently identical with Gericke's dinitrosulphobenzide (*Annalen*, **100**, 211). (2) Yellow, indistinct microscopic crystals melting at 116°, soluble in cold alcohol, readily soluble in ether, benzene, glacial acetic acid, and carbon bisulphide. This was found to be the dinitro compound of diphenylsulphoxide $(C_6H_4NO_2)_2SO$. (3) An oil not yet further investigated. —D. B.

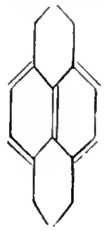
Constitution of Pyrene. E. Bamberger and M. Philip. Ber. **20**, 365—371.

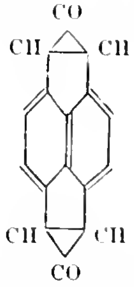
THE formation of naphthalenetetracarboxylic acid by the oxidation of pyrenic acid shows that the latter has the constitution $C_{10}H_4(C_2H_2.CO)(COOH)_2$. The fact that the two pairs of carboxyl groups in naphthalenetetracarboxylic acid have the ortho position points to pyrenic acid having the constitutional formula—



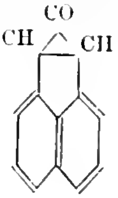
$$\mathrm{CO}{<}\begin{matrix}\mathrm{CH}\\ \mathrm{CH}\end{matrix}{>}\mathrm{C}_{10}\mathrm{H}_4(\mathrm{COOH})_2$$

[C_2H_2 : CO = 1 : 1′ and COOH : COOH = 4 : 4′]. The constitution of pyrene is represented by a combination of a naphthalene nucleus with two benzene nuclei thus:





Pyrenequinone.



Pyreneketone.

The constitutional formulæ of pyrenequinone and pyreneketone are respectively as above given.—D. B.

Notes on the Chemistry of Coal-tar Constituents. K. E. Schulze. Ber. **20**, 409—414.

Neutral Oils boiling at 170—210°.—This fraction consists of about 50 per cent. of resinifiable oils, 15 per cent. of trimethyl-benzenes, 15—20 per cent. of tetramethylbenzenes, and 15—20 per cent. of naphthalene.

Phenols.—The three cresols in coal-tar are present in the following proportions:—Metacresol about 40 per cent., orthocresol about 35 per cent., and paracresol about 25 per cent. The author finds that amongst the hydrocarbons and phenols in coal-tar meta-compounds predominate, thus of the xylenes the quantity of metaxylene is much greater than that of otho- or para-xylene; of the trimethyl-benzenes the 1 : 3 : 5 compound (containing 3 meta-positions) is largely in excess of the 1 : 3 : 4 and 1 : 2 : 3 compounds (containing each 1 meta-position). The same applies to the cresols and xylenols, the quantities of meta-cresol and 1 : 3 : 5 xylenol being much larger than those of ortho- or para-cresol and 1 : 2 : 4 xylenol.

Pyridine Bases.—The author has isolated from coal-tar pyridine Ladenburg's α-α¹-lutidine (this Journal, 1885, 394), α-γ-lutidine and γ-picoline.—D. B.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

A Novel Utilisation of Woods. J. Hlousek, Klein-Cerma, Bohemia. Eng. Pat. 6421, May 12, 1886. 4d.

WOOD-WOOL is spun into yarns either by hand or machine, after having been previously "moistened" or oiled.

Twined yarn is then prepared, and from the same carpet-like fabrics, figured fabrics, laces, cords and ropes are made.—H. A. R.

Improvements in the Treatment of Vegetable Textile Materials and of Threads and Fabrics made therefrom. F. Mollett-Fontaine, Madeleine-les-Lille, France. Eng. Pat. 7278, May 31, 1886. 8d.

THE object of this invention is to effect, in one single operation, the complete bucking (débouillissage) of vegetable materials, such as threads, etc., and so to obtain superior white goods in one bleaching either by means of the chlorine or by the electric process without affecting the fibre.—H. A. R.

VII.—ACIDS, ALKALIS, AND SALTS.

Observations on a Series of Bleaching Powder Chambers. L. Jahne, Petrowitz. Dingl. Polyt. J. **263**, 387.

THE series of bleaching powder chambers which served for the purpose of the experiments consisted of four chambers connected with each other by pipes. The chambers worked in such a manner that, while the first or strong chamber received an excess of chlorine, the unused portion of the gas passed into a second, third, or even fourth chamber, meeting there fresh lime by which to be finally absorbed. If a sample of the first chamber showed that the powder had attained the strength required, the gas from the stills was passed into the second chamber, which thus became the first or strong chamber. The gas in the chamber, now disconnected from the series, was allowed to act for some hours longer on the lime, and then drawn by means of the chimney draught over the fresh lime in the last chamber. Hereby the atmosphere of the chamber was freed from chlorine: no nuisance was created on opening the chamber for the purpose of packing; and, lastly, the residual chlorine was made available in the most rational form. A chamber was finished every 12 or 14 hours according to the quantity of lime, being a single or double charge.

1. *Observations on a series of chambers, one of which was finished every* 12 *hours.* (Single charge of lime. Designation of the chambers: A, B, C, D):—

Monday, 6 a.m.—A was emptied, filled, closed at noon, and remained the fourth of the series until 4 p.m. Direction of gas current: B, C, D, A. The gas was then aspirated from B to A.

6 p.m.—Sample from A=7 per cent. Cl; it now became third chamber. Gas current: C, D, A. B was opened and freshly charged.

12 midnight.—Sample from A=11·5 per cent. Cl. At 4 a.m. A became second chamber. The gas was then aspirated from C to B. Gas current: D, A.

Tuesday, 6 a.m.—Sample from A=12 per cent. Cl. Gas current: D, A, B. C was opened and freshly charged.

12 noon.—Sample from A=13·7 per cent Cl. D was disconnected at 4 p.m., and A became first chamber. Gas current: A, B, C.

6 p.m.—Sample from A=14·5 per cent. Cl. D was opened and freshly charged and connected as fourth chamber at 9 p.m. Gas current: A, B, C, D.

12 midnight.—Sample from A=35 per cent. Cl. A remained first chamber until 4 a.m., when it was disconnected and freed from gas.

Wednesday, 6 a.m.—A was opened and packed. A careful average sample showed the bleaching powder to contain 35·5 per cent. Cl.

These experiments show that the residual chlorine in a finished chamber may cause the formation of bleaching powder, containing 7 per cent. available chlorine in the last chamber. The powder in the second and third chambers increases in strength only to a moderate degree, until it receives the gas directly from the still, when it comes up to strength rather quickly.

2. *Observations on a series of chambers, one of which was finished every* 24 *hours.* (Double charge of lime. The gas from the stills acted on each first chamber from midnight until the following midnight):—

Monday, 8 a.m.—Gas current: C, D, A. B finished. Sample from surface of C=30·8 per cent. Cl; from bottom of D=5 per cent. Cl; from surface of A=11 per cent. Cl. Average sample of B=37·5 per cent. Cl. At 8 a.m. C had been first chamber for 8 hours. The gas from B was aspirated to A from 4 to 7 a.m., whereby the lime in A rose to 11 per cent. available Cl.

Tuesday, 8 a.m.—Gas current: D, A, B; C finished. Sample from bottom of D=22·2 per cent. Cl; from surface of A=15 per cent. Cl; from surface of B=5 per cent. Cl. Average sample of C=38·45 per cent. Cl.

Wednesday, 8 a.m.—Gas current: A, B, C; D finished. Sample from surface of A=34·3 per cent. Cl; from surface of B=6·7 per cent. Cl; from surface of C=11 per cent. Cl. Average sample of D=39·4 per cent. Cl.

Thursday, 8 a.m.—Gas current: B, C, D; A finished. Sample from surface of B=32·4 per cent. Cl; from surface of C=16 per cent. Cl; from surface of D=4 per cent. Cl. Average sample from A=36·9 per cent. Cl.

A rose in 4 days thus	11	15	34·3	(36·9) Cl
B " "	5	6·7	32·4	(37·8) Cl
C " "	11	16	—	(38·4) Cl

A statement is sometimes found in text-books that bleaching powder loses bleaching chlorine if the powder be treated with a very large excess of chlorine. This could not be confirmed on the large scale.—S. H.

On the Action of Sulphur on Ammonia and on Certain Metallic Bases in the presence of Water. J. B. Senderens. Compt. Rend. **104**, 58.

BRUNNER'S statement that sulphur is unacted on by aqueous ammonia below 75° C. is erroneous. Such a mixture, allowed to stand at the normal temperature, became yellow in colour in the course of three weeks, and red in a year, and was then found to contain ammonium polysulphides and hyposulphite (thiosulphate), which are, according to Flückiger, the usual products of the reaction, when effected in a sealed tube at 100° C. Sulphur is deposited from the solution on exposure to air. Precisely similar reactions, whether boiling or in the cold, result from the addition of sulphur to aqueous solutions of the alkali-earth bases. It is usually accepted that in the presence of water, sulphur is also without action on other metallic oxides, unless the oxide thus becomes reduced and sulphuric acid is formed. The author finds, however, that lead, silver, mercuric and cupric oxides, and red-lead under these conditions, in a sealed tube at 100° C., give sulphides and sulphates thus—$4PbO + 4S = 3PbS + PbSO_4$. Ferric oxide is but slightly, and zinc oxide not at all, decomposed. From thermo-chemical observations, it would seem that an insoluble base is thus decomposed by sulphur in presence of water at 100° if its heat of formation be relatively low; the decomposition requires a long contact, especially in the case of absolutely insoluble oxides, when it is important to first triturate the sulphur well with the oxide and a little water.—W. G. M.

On the Decomposition of Sodium Chloride by Phosphoric Acid. L. Blum. Publ. de l'Inst. R. G. D. de Luxembourg, 1886, 177.

FROM the author's experiments it is seen that sodium chloride may be decomposed by phosphoric acid in three ways. With the right proportions of the substances, the following reactions are possible:—

$$4NaCl + 2H_3PO_4 = Na_4P_2O_7 + 4HCl + H_2O.$$
$$2NaCl + 2H_3PO_4 = 2NaPO_3 + 2HCl + 2H_2O.$$

On evaporating a solution of sodium chloride with an excess of tribasic phosphoric acid, hydrochloric acid vapour escapes, increasing in quantity as the solution becomes concentrated. From this it would appear that sodium orthophosphate is formed at the outset, since orthophosphoric acid only passes into pyrophosphoric acid between 200° and 300° C.—W. G. M.

Improvements in Treating Hydrochloric Acid to obtain Chlorine, using the said Chlorine in the Manufacture of Bleaching Powder, and in Apparatus employed. J. Hargreaves, T. Robinson, and J. Hargreaves, Widnes. Eng. Pat. 5673, April 27, 1886. 6d.

HYDROCHLORIC ACID GAS, whilst hot, is mixed with a small quantity of copper chloride vapour, and passed through the decomposer of the Deacon apparatus, by which means the rate of decomposition is increased. The chlorine formed is passed into a bleaching powder chamber of special construction, so as to produce bleaching powder. Owing to a large amount of inert gases accompanying the chlorine, the chamber employed for the absorption of the gas by the lime contains a number of shelves. The weak chlorine enters at a distance of several shelves from the bottom, whereas strong chlorine, to be obtained as described further on, is introduced over the bottom shelf, and the weak bleaching powder formed on the top shelves is constantly stirred and exposed to strong chlorine gas until bleaching powder of high strength is obtained. The strong bleaching powder is then made to fall, by means of scrapers, into an air-tight box, from which it is conveyed directly by mechanical means into casks, where it is automatically pressed. Strong chlorine, to be used as previously described, is obtained by absorbing a separate portion of the dilute chlorine in milk of lime, and decomposing the solution of calcium hypochlorite thus obtained with hydrochloric acid in stoneware stills. Any copper chloride volatilised from the Deacon decomposer is condensed along with the hydrochloric acid in the wet purifier, and will therefore be found dissolved in the liquor of the stills, from which it may be precipitated and recovered.—S. H.

Improvements in Treating Pyrites and in Apparatus employed therein. Jas. Hargreaves and T. Robinson, Farnworth; and Jno. Hargreaves, Widnes. Eng. Pat. 5681, April 27, 1886. 6d.

This specification describes in full detail the arrangement of pyrites burners, regenerators and condensers, and the modifications of them recommended to suit various practical requirements, which constitute the twenty-two claims of the patentees.—W. G. M.

Improvements in the Manufacture of Sulphates of Soda and Potassa, and in Apparatus therefor. J. Hargreaves, T. Robinson, and J. Hargreaves, Widnes. Eng. Pat. 5682, April 27, 1886. 8d.

The invention relates to improvements in apparatus used in the Hargreaves' process. As a means of economising fuel, and to avoid leakage of air and products of combustion into the cylinders, and for increasing the rate of decomposition of sodium or potassium chloride by sulphurous acid, the latter is maintained in the cylinders under pressure. If there be no objection to the presence of a small quantity of iron in the resulting sulphate, as is the case when the sulphate is to be used for the manufacture of sodium hydrate or carbonate, the salt before entering the drying oven is moistened with the waste liquor running away from copper extracting works. The rapidity of the decomposition is augmented by the small quantity of iron present. To avoid the escape of noxious gases into the atmosphere when a cylinder recently finished is to be opened, such a cylinder is connected with another one filled with fresh salt, and after the doors at the bottom of the newly-charged cylinders are closed, the lid from the bottom discharging door of the finished cylinder is withdrawn, whereby the noxious gases from the finished cylinder pass to the bottom of that newly charged, where they are absorbed, at the same time heating the salt. As a means for internally heating the cylinders by means of fire, an arrangement of flues and heating chambers with an iron pipe or brick flue in front of two rows of cylinders is used. Every succeeding erection of cylinder apparatus demonstrates the economy in still further increasing the diameter of the cylinders. This, however, increases the difficulty of adequately supporting the cover of the cylinder, which is very heavy. It is now recommended to support the cover from the interior, by at least four columns, placed in such a position that the pillars stand beneath the joints, and the pillars themselves rest upon a part of the cylinder bottom, which rests immediately upon solid masonry. The pillars are made hollow and long enough to pass through the cover to the working floor on the top of the cylinder, so as to render visible the temperature of each part of the cylinder. The increased height and diameter of the cylinders also necessitate an arrangement to avoid an excessive pressure on the lower portion of the salt in the cylinders. They are therefore divided in several compartments by two or more grids, a working door being fitted opposite to each grid.—S. H.

Improvements in Apparatus for effecting the Absorption of Gases by Liquids. F. N. Mackay, London. Eng. Pat. 6282, May 10, 1886. 8d.

In refrigerating machines made upon the ammonia absorption plan, weak ammoniacal liquor is produced. The patentee deals with this by distillation in a still heated by an internal steam coil. An improved form of absorber is described consisting of a series of pipes cooled on the exterior by water; the ends are connected by bend pipes so that several are joined in series. The weak liquor fills the interior of the pipe, and the ammonia vapour is passed in through a perforated annular pipe; the excess gas in the first absorption tube is passed into the next by a bend communicating with another annular perforated pipe and so on; strong ammonia liquor flows off from the last of the series.
—C. C. H.

Improvements in the Manufacture of Bichromate of Potash. W. Simon, Baltimore. Eng. Pat. 6463, May 13, 1886. 4d.

Sodium chromate is converted into bichromate by the addition of a mineral acid, and to the solution of bichromate thus obtained, potassium chloride is added, when the decomposition takes place according to the following equation:—$Na_2Cr_2O_7$ and $2KCl = K_2Cr_2O_7$ and $2NaCl$. Potassium bichromate crystallises out on cooling, and whilst sodium chloride is removed by salting out, the mother liquor yields another crop of potassium bichromate crystals.—S. H.

Improvements in the Manufacture of Sulphurous Acid and other Sulphur Compounds, and in Apparatus employed in such Manufacture. J. M. Walton, Glossop. Eng. Pat. 16,491, Dec. 16, 1886. 8d.

The object of this invention is the manufacture of sulphites, etc., by a continuous process. The apparatus employed consists of a series of closed vats arranged in gradations, so that the water or alkaline solution to be impregnated with sulphurous acid descends continuously from one vat to the other, whilst the gas being admitted to the bottom of the lowest vat ascends continuously in the opposite direction. For this purpose the vats are connected by pipes for the flow of the liquor, and by another set of pipes for the passage of the gas. Each vat is also fitted with a mechanical agitator.—S. H.

Improvements in Apparatus used in the Manufacture of Ammonia Soda. T. Capper, Northwich. From Dr. S. Pick, Szczakowa, Galicia. Eng. Pat. 4388, March 29, 1886. 8d.

The invention relates to an apparatus for the continuous saturation of ammoniacal brine with carbonic acid (Figs. 1 and 2), and to a column for distilling ammoniacal liquor, having a mechanical agitator, and divided into two parts, in one of which ammonium carbonate is driven off, and in the other fixed ammonium salts are decomposed by milk of lime (Fig. 3). The vessels of the saturation apparatus (Figs. 1 and 2) are filled with ammoniacal brine, and the carbonic acid is forced in through the pipe B. The vessels are so arranged that the gas passes from one to another in such a manner that the fresh carbonic acid comes in contact with the most saturated liquor, and the most exhausted gas passes into the fresh ammoniacal brine. Three vessels are always working in one series, the fourth is filling with brine, and the fifth is emptied. For a better distribution of the gas, several perforated shelves D (Fig. 2) are fixed in the saturators, the holes being of a conical shape, in order to allow the bicarbonate to fall. After the saturation, the liquor is introduced into the pipe C of the distilling column A (Fig. 3) for the recovery of the ammonia. It drops from one section to the other, falling upon rounded plates H, and, being dispersed by them, comes in intimate contact with ammonia and steam, proceeding upwards from B. In this manner the volatile ammonia compounds are driven off. The liquor

FIG. 1.

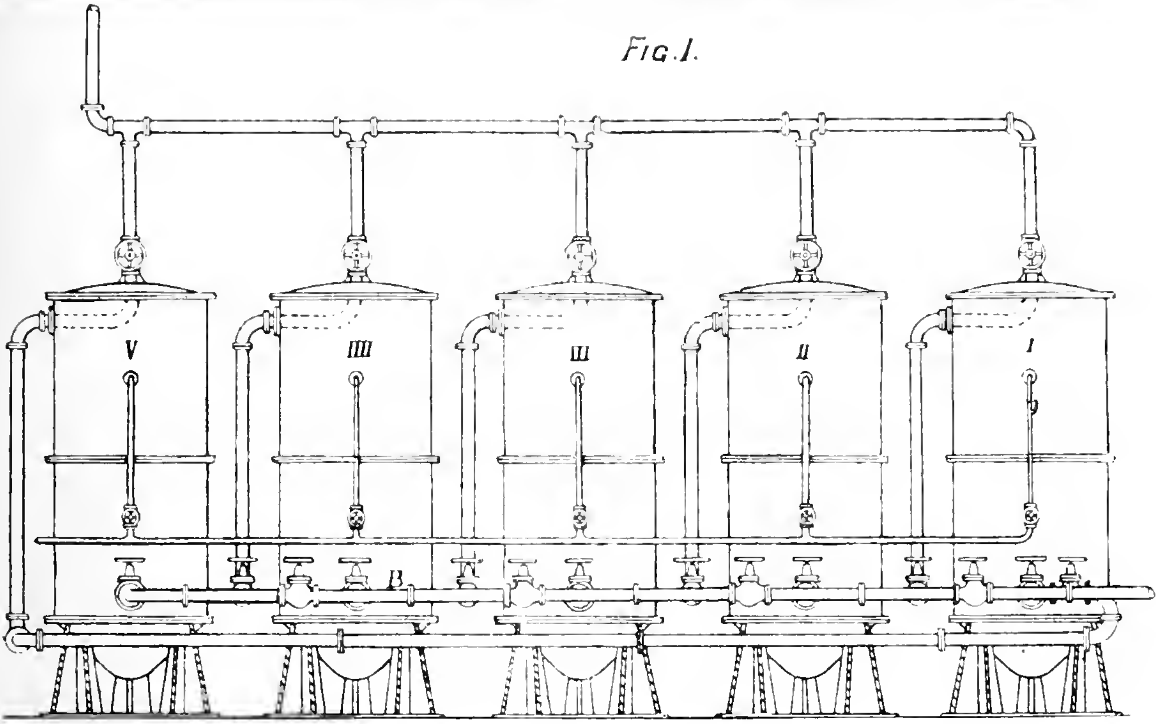


FIG. 2.

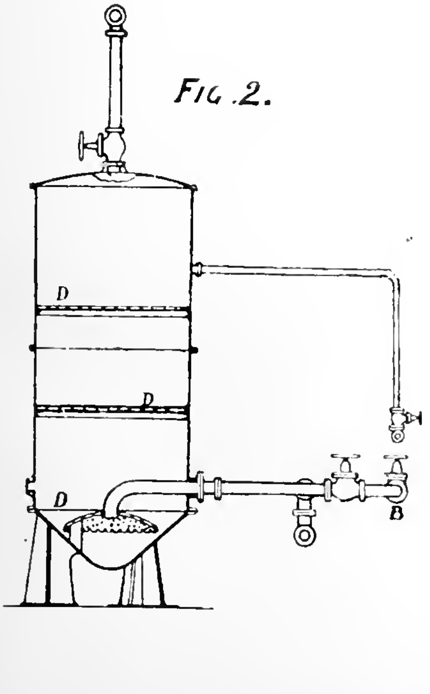

FIG. 3.

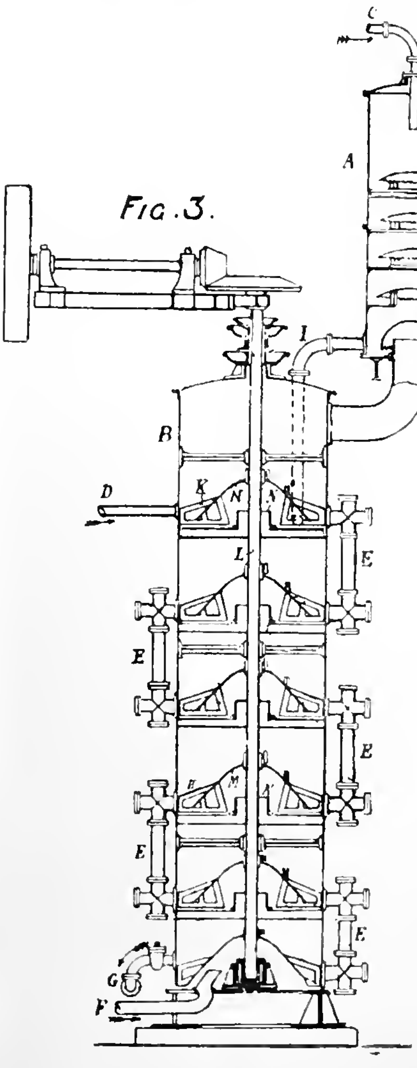

then descends into the top section of B, where it is treated with milk of lime, which is forced in at D and mixed with the liquor by the agitator K, fastened on the vertical shaft L. On this shaft there is, in each section, a fixed cap M, which covers the pipe N carrying the steam from the lower section. The steam is thus compelled to pass through the liquor. Overflow pipes E convey the liquor to the lower sections. The steam enters through F, whereas the waste liquor runs away through the pipe G.—S. H.

Process of making Pure Sulphuric Acid and Strong Sulphuric Acid in one Continuous Operation. A. M. Clark, London From J. Herreshoff, H. Nichols and G. Nichols, Brooklyn. Eng Pat. 1998, Feb. 8, 1887. 6d.

Sulphuric acid is first concentrated up to 86 per cent. SO_4H_2 in a suitable concentrator. The acid is then conveyed into another vessel, where it is compelled to flow in a zig zag course, being meanwhile exposed to heat to such an extent as to be further concentrated to about 95 per cent. to 96 per cent. SO_4H_2. Thence it flows into a third vessel of similar construction, which is heated high enough to drive off one half to two-thirds of the acid as a vapour, which is collected in a condenser, where it will be found to be sulphuric acid of 93·5 per cent. SO_4H_2 (66° B.) and of great purity. The remaining portion contains about 98 per cent. SO_4H_2.

—S. H.

Erratum.—April number, p. 292, 10th and 11th lines from bottom of 1st column, *for* "Three of these machines . . . length," *read* "One of these machines is sufficient for a chamber of 100ft. in length provided with three lute holes, as shown in Fig. 2."

VIII.—GLASS, POTTERY, AND EARTHENWARE.

An Improved Method of Annealing Glass or Articles manufactured therefrom. J. D. Watson, Glasgow. Eng. Pat. 15,099, Nov. 20, 1886. 4d.

The glass while in its plastic state is placed in moulds and deposited in a tank of boiling tallow, which is kept in its boiling state for a length of time depending upon the thickness of the glass to be annealed. Afterwards, before removing the glass, the tallow is allowed to cool slowly.—B. T.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Sugar as an Addition to Mortar. Zuckerind. **12**, 18.

Herzfeld has experimented with this mixture, recently reported to be so successful in India, on the new buildings of the Berlin Natural History Museum. To every 100 parts of a thick paste consisting of 1 of lime to 3 of sand, he added 2 parts of solid sugar (free from invert sugar) and, without further addition of water, used the mixture to plaster a wall. On the following day the plaster had hardened completely, as also a mortar made in a similar manner, and used in the building of a brick pillar. This mortar, which must be freshly made, and without too large an addition of water, is very binding and, as far as may be judged after a two months' trial, promises to be very durable. Good molasses gave a result apparently equal to the solid sugar.—W. G. M.

Improvements in the Manufacture of Cement or Plaster. C. J. Howe, London. Eng. Pat. 5843, April 29, 1886.

Gypsum or anhydrite, suitably broken, is boiled under pressure with an alkaline silicate, aluminate or borate, or of borax, or of borax and cream of tartar, or of sulphate of zinc or iron, or of barium hydrate or lime-water, or a combination of these ingredients. The fluid is then withdrawn, and if necessary a current of carbonic acid gas is first blown through the mass of gypsum, and next a blast of heated air or jet of superheated steam. The material is now calcined and reduced to powder. The method of manufacture may be modified in various ways.—E. G. C.

Improvements in the Manufacture of Cement. A. J. Boult, London. From A. Grasset and A. C. Mallat, Paris. Eng. Pat. 5975, May 3, 1886. 4d.

A powder, consisting of 8 per cent. of zinc oxide, 10 per cent. of minium, 5 per cent. of yellow ochre, and 5 per cent. of plumbago, is mixed with a liquid consisting of 99 per cent. of chloride of zinc, and 1 per cent. of perchloride of iron solution. The result is a cement which sets in about 30 seconds, adheres strongly to wood, glass, or metal, and is impermeable to water.

—E. G. C.

X.—METALLURGY, Etc.

On the Distillation and Electrolytic Treatment of Zinc-scum. B. Rosing. Zeits für Berg. Hütten. u. Salinenwesen, 1886, and Dingl. Polyt. J. **263**, 87—94.

In the desilvering of lead by means of zinc, a zinc-scum is obtained, from which part of the lead is first removed by cupellation. The concentrated scum, which varies in different works from 1½ to 10 per cent. of the lead worked, generally contains from 8 to 25 per cent. of zinc, 45 to 90 per cent. of lead, and 5 to 2·5 per cent. of silver. The oldest method of treatment, and that generally employed, consists in distilling off the zinc at a high temperature. This operation is performed in tilt or fixed furnaces, the latter being in the form of muffle, crucible, or tube furnaces, heated by coke or gas. The tube furnaces are nearly always heated by gas. The zinc is condensed in suitable receivers, and either used again for desilvering fresh quantities of lead, or converted into oxide by allowing it to burn in the air as it issues from the furnace. The lead containing 1 to 4 per cent. of silver is then run out. The fuel employed varies from 40 to 170 per cent. of the charge, according to the form of furnace used. The cost of working (wages, fuel, etc.) with a gas furnace amounts to about £1300 per 1000 tons of material. The distillation method is preferable to Flach's process (*Dingl. Polyt. J.* **225**, 67), and to Schnabel's steam and ammonia method (*Dingl. Polyt. J.* **240**, 149). The electrolytic process appears to be the most suitable of all the methods at present known. In this process the zinc-scum is spread out in powder upon a lead plate lying at the bottom of a wooden vat containing a solution of zinc sulphate. On passing an electric current through the fluid, the lead plate forming the anode, zinc is deposited from the solution upon the cathode, whilst a corresponding quantity of zinc is dissolved up from the zinc-scum. The action stops when the surface of the particles has become free from zinc. The mass is then heated in a cupellation furnace, and again electrolysed, the operations being repeated alternately until the zinc and lead have both been removed.

—A. G. G.

On the Behaviour of Pig-iron when heated in Wood Charcoal. A. Ledebur. Stahl u. Eisen, 1886, 777.

In earlier experiments conducted by the author on this subject (this Journal, 1886, 493), the samples of pig-iron employed contained but little manganese and phosphorus, and were comparatively rich in silicon ; he has, therefore, made experiments with low silicon metals, with varying amounts of the other elements. Nine test pieces of various kinds were packed separately, amidst small fragments of charcoal, in a pot such as is used for making malleable castings ; they were then heated to about 1000° C. for 108 hours. On examining the samples, it was found that in all malleable irons the percentage of carbon had increased ; thus in—

Fibrous wrought-iron	from	0·10 to 0·58	per cent.
Thomas steel	,,	0·11 to 0·26	,,
Cast steel	,,	0·40 to 0·65	,,

Similarly in a manganiferous (2·75 per cent. Mn) cast iron for the Thomas process the carbon had increased from 2·63 to 3·27 per cent., whilst in a refined Lowmoor-iron, with but a trace of manganese, it was constant at 3·5 per cent. ; in all the other specimens there was actually a diminution in the amount of carbon. Thus, although confirmatory of previous experiments, no further light is thrown on the cause of the decrease noted with so many samples of cast-iron. The silicon and phosphorus percentages alike remain unchanged. With the alteration in composition was a corresponding change in the appearance and in the physical properties; all specimens with less than 1 per cent. of manganese having become granular, soft and comparatively tough, whilst the manganese Thomas cast-iron, above alluded to, remained unaltered in fracture and in brittleness.—W. G. M.

Improvements in the Smelting and Refining of Gold, Silver, Copper, Zinc, Lead and Tin Ores, and in Furnaces therefor. J. M. Bennett, Ruchill, Lanark, N.B. Eng. Pat. 6300, May 10, 1886. 8d.

A CUPOLA, with closed bell and hopper top, has tuyeres for the admission of air and steam throughout its height; in front at the bottom is a closed receiving chamber, provided with slag and tap-holes, and communicating with the cupola; and on either side of the base is an open hearth furnace of suitable size and shape, so arranged that the gases, which pass downwards from the cupola, are utilised as a source of heat, the whole products being finally passed from the flues through some form of condenser or dust-collecting apparatus. The metal which has accumulated in the receiver may, if desirable, be there subjected to the action of an oxidising blast; it is then tapped, and ladled into one of the reverberating furnaces, which, in dealing with gold and silver ores, would be constructed as a bone-ash refining furnace, with copper ore as a copper refinery, or with other metals according to their requirements.—W. G. M.

Improvements in the Manufacture or Production of Metallic Alloys. T. Slater, London. Eng. Pat. 6550, May 15, 1886. 6d.

A MIXTURE of 55 per cent. of chromium oxide, 33 of ferric oxide, 18 of alumina, and smaller proportions of borax, calcined aluminium sulphate, silica, manganic oxide, and magnesium carbonate, are to be added in the form of powder to metals or alloys. The powder is to be added very gradually, and with constant stirring, with the object of hardening and increasing the tensile strength of the metal.—W. G. M.

Improvements relating to Amalgamating Apparatus for Separating Metals from their Ores. H. H. Lake, London. From W. White, New York, U.S.A. Eng. Pat. 463, Jan. 11, 1887. 6d.

A SHALLOW circular pan, with inwardly re-curved edge, is rotated by suitable mechanism from beneath. Within the pan, and shaped conformably, is a stationary disc, having concentric but broken ridges on its lower side, which at all points are nearly in contact with the bottom of the pan, the alternate rings being broken in different positions. Mercury is poured between the pan and the disc, ore is fed in through a central hopper in the latter, when, by the centrifugal action of the former, it is forced towards the circumference, and, by the aid of the broken ridges, takes a zig-zag course, always in contact with the mercury, and finally overflows from the curved edge. The amalgam may be drawn off through a cock beneath. —W. G. M.

XI.—FATS, OILS, AND SOAP MANUFACTURE.

Vaselin. C. Engler and M. Boehm. Dingl. Polyt. J. **262**, 468—475 and 524—530.

VASELIN is the substance extracted from petroleum residues, whilst the mixture of heavy mineral oil (*paraffinium liquidum*) with ceresin (*paraffinium solidum*) is called "artificial vaselin" by the authors. For the preparation of vaselin two kinds of Galician petroleum oil were employed. Both oils were highly dichroic, had a green colour by reflected light, a colour varying from yellowish to brownish red by diffused light, and yielded the following, when subjected to fractional distillation:—

	Specific Gravity at 15°.	Fraction below 150°.		150—290°.	
		Per cent. by vol.	Per cent. by weight.	Per cent. by vol.	Per cent. by weight.
Oil I.	0·812	30·2	26·7	35·9	35·5
Oil II.	0·820	21·8	20·0	51·7	51·2

	290—340°.		Above 340°.	
	Per cent. by vol.	Per cent. by weight.	Per cent. by vol.	Per cent. by weight.
Oil I.	5·3	6·5	27·7	31·1
Oil II.	8·8	9·4	17·0	18·9

For the manufacture of vaselin from these oils, two processes were employed. (1) The oils were distilled until the residue assumed a butter-like consistence. The residue was then dissolved in petroleum spirit, bleached by passage through animal charcoal filters, and the solvent expelled by distillation with steam. The vaselin thus obtained is a colourless, translucent ointment melting at 32° and exhibiting no crystalline structure. (2) The oils were bleached and subjected to distillation in a vacuum (column of mercury 10—15mm.) to 250°. The product is colourless, translucent, free from odour and exhibits the following properties:—

	Yield.	Specific Gravity.	Melting point.
Oil I.	13·8	0·8809	30—31°
Oil II..........	13·2	0·8785	30—31°

The composition of these vaselins is illustrated in the subjoined table:—

	From Residues.		From Oil I.			From Oil II.	
	I.	II.	III.	IV.	V.	VI.	VII.
C	86·99	86·67	86·30	86·51	86·55	86·14	86·17
H	13·14	13·15	13·99	13·73	13·74	13·50	13·72

It will be seen from these results that vaselin is composed entirely of hydrocarbons; moreover, the oils obtained by subjecting the bleached petroleum to fractional distillation, were found to contain carbon and hydrogen exclusively, both oxygen and sulphur being absent. The bleaching process appears to remove all oxygenated constituents, and increases the amount of saturated hydrocarbons, by retaining the less highly hydrogenated hydrocarbons. Attempts were made to increase the melting point of vaselin by distilling part of it over in a vacuum. It was not, however, possible to raise the melting point more than 2 or 3 degrees, whilst on continuing the distillation, the melting point was actually reduced, probably owing to the decomposition of the product. By dissolving vaselin in ether and subjecting the ethereal solution to fractional precipitation by means of alcohol, the authors succeeded in separating vaselin into a solid and a liquid portion. 100grms. of vaselin from oil II. gave 40·8grms. of solid vaselin having a sp. gr. of 0·8836 and melting at 40°, and 59·2grms. of liquid vaselin having a sp. gr. of 0·8809 and solidifying at —10°. Both vaselins were similarly constituted and had approximately the same boiling points. American vaselin, melting at 32—33°, gave 14 per cent. of solid vaselin melting at 49—50°, and 86 per cent. of liquid vaselin. Although artificial vaselin could be separated into solid and liquid products, a wide difference was observed between the chemical and physical properties of the component parts. On subjecting the solid and liquid portions of natural vaselin to distillation, both began to boil at 240—245°, the solid yielded 66 per cent. of distillate at 340°, and the liquid 75 per cent. The residue from the solid portion was amorphous and had a melting point of 40—41°, whilst the distillate was crystalline and melted at 36—37°. Both the residue and distillate of the liquid vaselin were fluid. From the fact that the solid hydrocarbons present in vaselin are amorphous and only assume a crystalline structure when subjected to distillation, the authors conclude that paraffin does not, as a rule, exist in crude petroleum in a crystalline form; moreover, they consider the solid hydrocarbons found in the crude oil to be chemically identical with ozokerite, which is frequently regarded as petroleum in a dried-up condition. It is, of course, possible that in isolated cases paraffin may exist in petroleum, in a fully developed state. The authors are, however, of opinion, that as a rule it occurs in a transition form. The difference between natural and artificial vaselin is considerable. Artificial vaselin is resolved into oil and ceresin when subjected to distillation, and differs sensibly in viscosity, as shown by the following figures obtained with Engler's apparatus and compared with water as the standard:—

	45°	50°	80°	100°
Natural American Vaselin ..	1·8	3·7	2·1 ..	1·6
Artificial Vaselin	Ceases to run out.	Ceases to run out.	1·5 ..	1·2

From a series of experiments made with a view to ascertain whether vaselin acquires an acid reaction by keeping, it is inferred that lard has a greater tendency to become acid than natural or artificial vaselin, whilst of the latter, the artificial product absorbs the least amount of oxygen.
—D. B.

Separation of Stearic and Oleic Acids. Dingl. Polyt. J. **263**, 48 and 49.

In the ordinary method of separation from the mixture of fatty acids, which is obtained by saponification of tallow or palm-oil by means of lime, the solid stearic acid (so-called "stearin") is removed by passing through a filter-press at the ordinary temperature. Under these conditions a considerable quantity of stearic acid remains dissolved in the liquid oleic acid. By moderate cooling, a further quantity of this stearic acid can be obtained without solidification of the oleic acid. For this purpose a revolving drum A is employed (Fig. 1), containing cold water supplied from a cooling machine through the tube *c*, and carried off by another tube. The drum dips into the trough *f*, containing the liquid fatty acids, which are carried round in a thin layer upon the surface. During the revolution the oil solidifies, and is scraped off by the scraper *h* into the reservoir F, from which it is pumped through a Farinaux filter-press (Figs. 2 and 3). An increased yield of 4 per cent. on the raw material is obtained, and the oleic acid has a higher value on account of its greater clearness.—A. G. G.

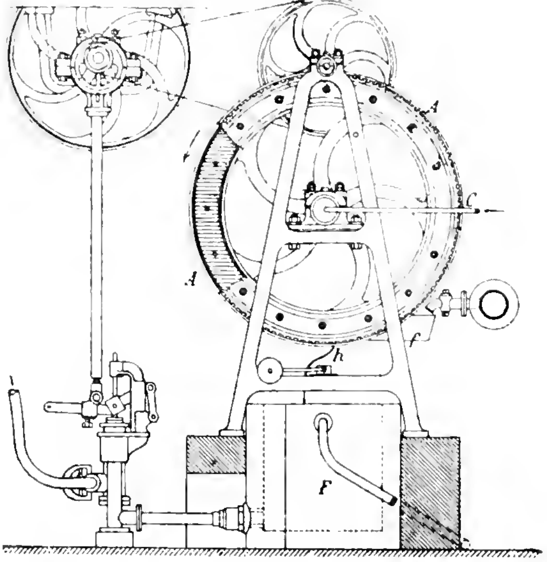

Fig. 2.

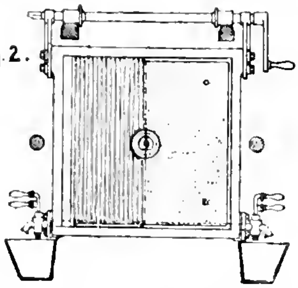

Fig. 3.

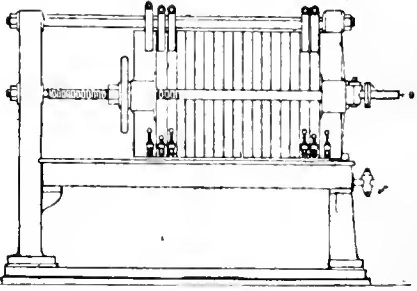

On the Oil of the Japanese Sardine Villon. Corps. Gras. Ind. 1887, 178.

This oil, which was introduced into Europe two years ago, but which found little acceptance on account of its most unpleasant smell, due to the crude manner of its extraction, is considered by the author to be capable of profitable application in dyeing, and in the stearine and soap manufactures. The oil is chiefly obtained from the island of Yesso, and from the peninsula of Ava, near Yokohama, and is extracted from the fish, either by boiling with water or by allowing them to rot in heaps, when the greater part of the oil flows out, the residue being obtained by pressure. This oil contains about 30 per cent. of solid fat, and begins to run at 20—22° C. It is refined in Yokohama by being heated for an hour at 50—60° C., in iron boilers of 100 litres capacity, and then run off into wooden vessels, where it soon separates into three layers. The upper layer is liquid and clear oil, the middle layer consists of solid fat, and the lower is water, with albuminous substances and portions of the fish. The liquid oil, when light, costs in Hamburg 40 marks per 100kilos., and about 37·5 marks when brown. The solid fat is re-melted, filtered and run into boxes, in which it solidifies. This fat is yellow, and is sold in Rotterdam as fish-stearin or fish-wax, at 43 marks per 100kilos. In the Indo-Chinese colonies, and especially in Cambodia, the production of this fish fat might be very considerable, about 400,000kilos. a month could readily be exported. Experiments as to the application of this new product would be of great value.—W. D. B.

Improvements in Apparatus for the Extraction of Oils or other Vegetable Juices. A. J. Boult. From E. Oppelt, of Alors, Spain. Eng. Pat. 5792, April 28, 1886. 8d.

THE apparatus, of which a drawing is given, consists essentially of a hollow cylinder, the sides of which are formed of rings in parts, placed one above the other, and joined by bolts, and also fixed by bolts to a bedplate. The first set of bolts serves also to regulate the space between the rings for the escape of the extracted liquid, while the second set serves as hinges for opening or closing the segments of the rings. Pressure is applied by hand, steam, hydraulic or other convenient power, the material to be pressed being divided into layers by metal discs.—W. L. C.

Toilet and Washing Soap. R. Wright. Eng. Pat. 16, Jan. 1, 1887. 4d.

FOR mixing borax with soap.—W. L. C.

Method for the Separation of Cholesterin Fats from Commercial Wool Fats, and from the Lyes of Wool-washing Works. H. G. Laogbeck and R. E. Ritsert. Eng. Pat. 6210, May 7, 1887. 4d.

THE raw wool fats are treated with boiling alcohol, containing 10 per cent. of ether. Free fatty acids, free cholesterin, isocholesterin, and volatile fatty ethers, are dissolved, the residue being mainly true cholesterin fats. Or, the whole raw fat may be dissolved in ether, and the cholesterin fats precipitated therefrom by the addition of alcohol.—W. L. C.

XII.—PAINTS, VARNISHES, AND RESINS.

Improvements in the Manufacture of Oxide of Iron Pigment Colour. R. Lavender, Talywain, Monmouthshire. Eng. Pat. 6370, May 11, 1886.

COPPERAS is spread on heated iron plates, and the water of crystallisation thus driven off. Cast-iron trays, containing the crushed material in layers of less than an inch thick, are then introduced into retorts set in a furnace, like gas retorts, and heated to a full red heat, but not beyond. The retorts are connected with a sulphuric acid chamber, air having free passage through the retorts during the operation. This is essential for the complete removal of the sulphur. The pigment is produced in a condition ready for use and requires no lixiviation or other preparation.—E. G. C.

A Novel Protective Varnish. W. Dick, Leytonstone. Eng. Pat. 2498, Feb. 17, 1887. 4d.

TWELVE POUNDS of Egyptian asphaltum are kept at the boiling point for four hours; to this, three pounds of red lead and four pounds of litharge are added during the first two hours. Three gallons of boiled oil, three pounds of very-finely ground plumbago, and six pounds of finely pulverised Italian asbestos, are next introduced into the mixture. Finally, a solution of indiarubber (one pound of finely-cut virgin indiarubber in two pounds of benzene) is poured in, and the solution is now kept boiling, with constant stirring, for one hour, at the expiration of which it is allowed to cool. If necessary, the varnish may be thinned with turpentine.—E. G. C.

XIII.—TANNING, LEATHER, GLUE, AND SIZE.

Improvements in Tanning and Stuffing Leather. A. M. Clark, London. From J. B. West, Durant, Mississippi, U.S.A. Eng. Pat. 13,283, Oct. 18, 1886. 6d.

THIS is an improvement on Peter's process for tanning and stuffing leather. The principal differences are:—(1) The hide is soaked in clear water, the hard flesh removed by a light currying knife, and the hide again soaked in clear water before liming. (2) After liming and removing the hair it is bated in water only instead of with the addition of sulphuric acid, bran, and buttermilk. (3) The hides are tanned in the following mixture, which is strengthened as required during the process: 8 gallons water, 3lb salt, ¼lb. saltpetre, 10lb. gambia, and 1lb. sulphuric acid. When half-tanned the hides are taken out, beamed, and again immersed in the tan liquor. (4) They are soaked for 30 to 60 minutes in lye (1lb. caustic to 20 gallons water), and next in clean water for one or two days; after which they are sleeked and brushed and hung up to drain. (5) Boiling hot tanners' oil (fish oil and bees wax) is poured on to the grain side and well brushed in. Twelve hours afterwards a boiling hot mixture of 1 part tar, 1 part tallow and 2 parts tanners' oil is brushed into the flesh side. By using these mixtures hot the hide is much more thoroughly permeated, and rendered waterproof.—R. L. W.

XIV.—AGRICULTURE, MANURES, Etc.

Composition and Formation of "Acid Soil" in Dutch Alluvial Districts. J. M. van Benmelen. Bied. Centr. **15**, 795—806.

THIS communication contains the results of extensive investigations on "acid soils" in various alluvial districts in Holland. The changes occurring in clay soil under the influence of brackish or sea-water and decaying vegetable matter; the migration and transformation of the substances produced; the microscopic character of the "acid soils;" their chemical composition at different depths, and the origin of the most characteristic constituents; and the effect of aeration and drainage are described more or less in detail and explained. The formation of "acid soils" is observed to take place in four stages. During the first stage the ground is covered with reeds and saturated with water containing gypsum. In the second stage the air is excluded from the soil, gypsum disappears; iron sulphide, free sulphur with little or no iron sulphate replace it, and the soil is either not acid at all or only slightly so; such soils, for instance, are soils in a state of transition between clay and moorland, or the soil from the lower layers of "acid soils." In the third stage the air has limited access to the soil, and the quantity of iron sulphate has increased, whilst pyrites and sulphur have diminished. In the fourth stage in the aeration and drainage pyrites and sulphur have entirely disappeared, and the soil contains large quantities of basic iron sulphate; if, however, sulphates and sulphuric acid gain access, even in this stage, iron sulphide is formed from part of the sulphuric acid. The layers of soil are acid when they do not contain a sufficient quantity of bases in combination with carbonic, humic, or silicic acids: but when they contain these substances in sufficient quantity they are not acid, but are rich in gypsum.—D. A. L.

Experiments with different Phosphates and Chili Saltpetre on Moorland. V. Photz-Pollingen. Bied. Centr. **15**, 826—828.

THE experiments were conducted on recently reclaimed and previously unmanured moorland. Eight plots were arranged; all received three centners of kainite per morgen, one without other manure, three with the addition of 40 pounds (German) phosphoric acid as basic slag, two with this amount of phosphoric acid as precipitated calcium phosphate; of the other two one received in addition ½ centner Chili saltpetre, and one a double dressing of phosphate. As a matter of profit the slag was the most remunerative; from a manurial point of view the two forms of phosphates were of equal value, whilst both the double dressing and the nitrate proved superfluous. Cultivated moorland which had already yielded some crops produced last year, when manured with four centners kainite and two centners basic slag per morgen, 1360 pounds of wheat, 800 pounds rye, 98 centners (magnum bonum) potatoes, 80 centners sugar-beet. (See also this Journal, 1886, 541.)—D. A. L.

Tetracalcium Phosphate and Basic Slag. E. Jensch. Ber. **19**, 3093—3097.

IT is now well known that the phosphoric acid of basic slag is present in a state differing both in appearance and chemical behaviour from tricalcium phosphate, and it has been suggested it is present in the slag in the form of tetracalcium phosphate. The author of the present note has attempted to synthesise this compound by strongly igniting tricalcium phosphate with lime prepared from marble, and although he has not succeeded in reproducing a phosphate in the crystalline form observed in basic slag, he has nevertheless effected a chemical change. The unignited mixture contained 0·26 per cent. of citrate soluble phosphoric acid; after exposure to the air for a quarter of a year it had absorbed 1·20 per cent. of water of hydration, 2·19 per cent. of carbonic anhydride, and the citrate soluble phosphoric acid had increased to 0·38. Portions of the same mixture after ignition yielded 3·84 per cent. citrate soluble phosphoric acid, and after the quarter year exposure to air had absorbed 0·92 per cent. water of hydration, 2·04 per cent. carbonic anhydride, whilst the percentage of citrate soluble phosphoric acid had increased to 5·62 per cent. From evidence afforded by numerous analyses of basic slag the author is of opinion that after the formation of the tetracalcium phosphate there is little or no uncombined lime present in the slag, it being in fact in combination as silicate, ferrate, manganate, etc. A careful inquiry into the question as to the presence of iron phosphide in the slag leads to the conclusion that the quantity is at any rate but small, and may possibly amount to 1·5 per cent. of the phosphoric acid found. It is, moreover, shown by experimental plot cultivations of oats in garden soil and in loamy sand soil, that under the influence of the chemical agencies of the soil plant-roots and Chili saltpetre iron phosphate is decomposed and rendered soluble within three months.—D. A. L.

Experiments on Iron Sulphate as a Manure during 1886. A. B. Griffiths. Jour. Chem. Soc. 1887, 215—224.

THE experimental plots were in all cases an acre each in area. The plot of grass grown with farmyard manure only yielded 3496lb. hay; a similar plot with ½cwt. ferrous sulphate in addition yielded 6962lb. The latter hay (dried) contained 13·01 per cent. albuminoids, and 48·29 per cent. soluble carbohydrates; the former 9·68 per cent. albuminoids, and 46·24 per cent. carbohydrates; the ash of the untreated hay contained 1·22 per cent. Fe_2O_3 and 5·36 per cent. P_2O_5, of the hay receiving iron sulphate 4·46 per cent. Fe_2O_3 and 7·67 per cent. P_2O_5.

Two plots of mangel wurzel were grown with 10 tons farmyard manure, and top dressed with a mixture of kainite, nitrate of soda, superphosphate, and salt. One of them received in addition ½cwt. ferrous sulphate. The latter yielded 97,682lb. roots, and the former 78,369lb., a difference in favour of the iron sulphate of six tons per acre. The roots grown with this salt contained 2·89 per cent. albuminoids, and 11·21 per cent. soluble carbohydrates; the ash of the roots 4·25 per cent. Fe_2O_3, and 12·24 per cent. P_2O_5; and the ash of the leaves 5·42 per cent. Fe_2O_3. The roots grown without ferrous sulphate contained 1·90 per cent. albuminoids, and 9·32 per cent. soluble carbohydrates; the root ashes 2·42 per cent. Fe_2O_3, and 9·96 per cent. P_2O_5; and the leaf ashes 3·29 per cent. Fe_2O_3.

The plot of beans grown with farmyard manure only, yielded 4726lb. dry crop: that with ½cwt. ferrous sulphate in addition, 5929lb. dry—50 bushels of beans against 30 bushels. The beans and straw grown with iron sulphate showed also a slight superiority in albumenoids and soluble carbohydrates. The ash of the beans from iron sulphate contained 4·821 per cent. Fe_2O_3, and 40·65 per cent. P_2O_5; the ash of those grown without iron sulphate contained 1·099 per cent. Fe_2O_3, and 37·424 per cent. P_2O_5. These results obtained with beans in 1886 are exactly similar to those obtained in 1883 and 1884.

Tried on palms and indiarubber trees in the house, ferrous sulphate also showed good results; the ashes of the leaves of these plants also contained more Fe_2O_3 than those untreated with $FeSO_4$.

Half a cwt. of ferrous sulphate tried against 2cwt. kainite on potatoes which were grown with farmyard manure gave nine tons tubers against six tons with the kainite: the same excess in albuminoids, soluble carbohydrates, ferric oxide, and phosphoric acid were noticed in this case as in the others.

All the experiments which have been made with iron sulphate appear to show that it increases the quantity of chlorophyl formed in the leaves, and in this way augments the assimilating power of the plant. It has also antiseptic and antifungoid properties, and the potatoes grown with it were quite free from disease, whereas those grown with the kainite showed signs of disease.

—J. M. H. M.

XV.—SUGAR, GUMS, STARCHES, Etc.

Raffinose. Haedicke and Tollens. Ztschr. f. Zukerind. **37**, 17.

THE authors have investigated the products formed by the inversion of raffinose. On treating 40grms of raffinose with 400cc. of water and 25cc. of sulphuric acid of 1·156 sp. gr., and heating on a water bath for 3½ hours, the rotatory power was reduced from $[\alpha]D = +104·5°$ to $[\alpha]D = +21·46°$. The solution was then neutralised and evaporated to a syrupy consistency. On cooling galactose crystallised out. Its rotatory power was found to be $[\alpha]D = +80·33°$ to $+80·71°$. It is bi-rotatory, reduces Fehling's solution, and on oxidation with concentrated nitric acid yields 74—78 per cent. of mucic acid. On treating 60grms of raffinose with 540cc. water and 30cc. of sulphuric acid, *i.e.*, inverting the raffinose more slightly, the mixture yields levulose when heated for one hour at 80°. On reducing the inverted syrups with sodium amalgam, a mixture of equal parts of mannite and dulcite is obtained melting at 160°.

—D. B.

Levulinic Acid. Block and Tollens. Ztschr. f. Zuckerind. **37**, 27.

WHEN this acid is saturated with baryta, and the mixture kept at rest for a few months, the barium salt crystallises out in the form of fine needles having the composition $(C_5H_7O_3)_2Ba+2H_2O$. It is a colourless salt readily soluble in water. The strontium compound may be obtained in a similar manner. It forms brilliant prismatic crystals, which are readily soluble in water. Attempts to obtain a crystallisable magnesium salt have hitherto been unsuccessful.—D. B.

Erythrol. A. Colson. Compt. Rend. **104**, 113.

IF erythrol has the constitution $CH_2(OH).CH(OH).CH(OH).CH_2(OH)$ it should yield erythric and tartaric acids by oxidation. Hitherto it has not been possible to obtain satisfactory results in this direction:—When erythrol is treated with phosphorus bromide, a bromide $C_4H_6Br_4$ is obtained which melts at 112° and is identical with the crotonylene tetrabromide prepared by Henninger. If heated with bromine in sealed tubes at 175° a mixture of a solid and a liquid product is obtained. Both are isomeric, and have the composition $C_4H_4Br_6$. The solid crystallises in needles, which melt at 167°—169° and dissolve readily in chloroform, but are only sparingly soluble in alcohol and ether. The liquid forms an oil, which dissolves readily in ether and chloroform, but is only slightly soluble in alcohol. On heating the liquid product with dilute potash in sealed tubes it yields a potassium salt, which is free from bromine, only slightly soluble in water and in some respects resembles potassium hydrogen tartrate. It does not, however, give precipitates with salts of silver or calcium, has no action on polarised light, but yields an insoluble lead salt. This compound is in all probability the potassium salt of erythric acid. It would seem, therefore, that the liquid is the unsymmetrical $CBr_3.CHBr.CHBr.CH_2Br.$, whilst the solid bromide has the constitution represented by the formula $CHBr_2.CHBr.CHBr.CHBr_2$. The investigation is still being pursued.—D. B.

A Process for Revivifying Spent Charcoal. M. P. W. Boulton, B. E. R. Newlands and Edward Perrett, London. Eng. Pat. 15,897, Dec. 24, 1885. 3d.

FOR the purpose of revivifying spent charcoal which has been used for the purification of sugar or other liquors, the inventors use two vessels, the one containing refractory materials previously heated by fire, the other the charcoal which is to be operated upon. Gas, steam or some other elastic fluid is caused to pass first through the hot vessel and then through the charcoal, which is made to descend gradually through the second vessel in a direction opposite to that taken by the steam. The apparatus is fully described and illustrated in the specification, and details of the method of working are also given.
—A. J. K.

A New or Improved Diastasic Saccharine Substance, and Method of Manufacturing the Same. L. Cuisinier, Brussels. Eng. Pat. 1820, Feb. 8, 1886. 6d.

THE author claims the discovery of a new diastasic substance, which he calls "Cerealose." It has a more sugary flavour than the solid maltose of Dubrunfaut, and is more easily manufactured. If maize be simply steeped in cold water for two or three days a special kind of diastase is developed, which the author calls "Glucase." By the action of this substance upon starch "Cerealose" is obtained. Cerealose is a mixture of varying and uncertain composition containing from 48 to 72 per cent. dextrose, from 5 to 24 per cent. maltose, and from 1 to 12 per cent. of dextrin.—A. J. K.

Improvements in Filtering and Decolourising Sugar, Syrups, and Other Liquids and in Preparing a Material therefor. M. F. Heddle, D. C. Glen, and Duncan Stewart, Glasgow. Eng. Pat. 3116, March 5, 1886. 6d.

THE material used is an earthy compound of a class known by various names—diatomite, desmid earth, white peat, kieselguhr or bergmehl. A special quality found at Black Moss and Kinmordie in the county of Aberdeen, is said to be most suitable for the purpose. After being heated in a kiln, to remove volatile constituents and to carbonise it, the prepared material is known as hedylglin, and may be used instead of animal charcoal for purifying sugar syrups and other liquors. It can be revivified by the usual method of washing, exposure to air or ignition.—A. J. K.

Improvements in the Process of Purifying Saccharine Juices. R. Englert and Dr. F. Becker (Prague). Eng. Pat. 3196, March 6, 1886. 6d.

THE saccharine juices obtained either from beetroots or sugar canes by the diffusion process are first defecated as usual with lime and carbonic acid, and then further purified by the use of sulphite of alumina or iron, hydrosulphurous acid or of a sulphite of some other base than alumina or iron. By a judicious use of one or other, or of several of these substances in combination with the lime and carbonic acid treatment, it is claimed that the juices are so thoroughly defecated as to render unnecessary the use of animal charcoal.—A. J. K.

Improved Process for the Insaccharification of Molasses and Sugar-Syrups, and the Simultaneous Production of Oxalates from the Salts contained therein. C. D. Abel, London. From Messrs P. Schwengers Söhne, Uerdingen, Germany. Eng. Pat. 4801, April 6, 1886. 6d.

MOLASSES and sugar-syrups are perfectly soluble in concentrated methyl alcohol, and on treating this solution with alcohol and oxalic acid the salts contained in the molasses are separated therefrom, together with the sugar, in the form of oxalates leaving the organic acids and nitrogenous constituents in solution. On these two facts the following process depends. The molasses or sugar syrups are dissolved in methyl alcohol or a mixture of methyl and ethyl alcohols; 110lb. molasses polarising 50 per cent. would require 7 pints of methyl alcohol. The dissolved molasses is now further mixed with oxalic acid and excess of ethyl alcohol, in which latter the oxalic acid is previously dissolved. The sugar and oxalates separate out as a precipitate. This is separated by pressure from the liquid and dissolved in water. By further addition of alcohol the oxalates separate out from the sugar solution. Any trace of oxalic acid remaining in the sugar solution is removable by lime, and the solution has then a purity co-efficient of 99 per cent. About 80 per cent. of the sugar originally in the molasses is recoverable by this process.
—A. J. K.

Compound for use in Preparing Starch or Flour Size for Yarn, Textile or other Fabrics. C. N. Waite, Medford, Middlesex, Mass., U.S.A. Eng. Pat. 14,117, Nov. 2, 1886. 4d.

FOR the purpose of neutralising, dissolving and softening starch or flour size to be used on yarn or textile or other fabrics, the author uses the following mixture:—1lb. of crystallised sodium sulphate, ¼lb. of zinc oxide, 5oz. to 6oz. of zinc chloride and 100lb. of starch are boiled together with 150gals. to 300gals. of water, according to the thickness of the starch required. These portions may be varied to suit different circumstances. Zinc oxide neutralises any free acids which may be present, and prevents the conversion of starch into dextrin, which is an economy, since starch has a greater thickening power than dextrin. Sodium sulphate is used partially to dissolve the zinc oxide, and may be replaced by equivalent quantities of sodium chloride, ammonium chloride or ammonium sulphate. The zinc chloride renders the size soft and pliable when dry, and instead of it may be used glycerin, sulphate of soda, or any other softener. The chief novelty which is claimed is the perfect neutralisation and solution of starch or flour with zinc oxide, which at the same time has no alkaline reaction.
—A. J. K.

Improvements in Apparatus for Extracting the Saccharine or other Soluble Matters from Sugar-Cane and other Substances. M. A. Perret, Paris. Eng. Pat. 1931, Feb. 7, 1887. 1s. 3d.

THIS patent is not capable of abstraction without reference to the diagrams in the specification, which are numerous and detailed.—A. J. K.

Improvements in the Treatment of Grain for the Manufacture of Starch or Glucose. H. L. Sulman and E. E. Berry, London. Eng. Pat. 2138, Feb. 11, 1887. 4d.

THE usual method of macerating rice, wheat or other cereal preparatory to its conversion into starch or glucose is by means of caustic soda at the ordinary atmospheric temperature. The use of lime water has also been patented. The authors use lime water and an excess of slaked lime, and work at temperatures as high as is possible without causing the starch granules to burst. The advantages claimed are (1) shorter time taken in the macerating process; (2) no danger of the lime being completely neutralised, as is the case when lime water only is used; (3) larger amount of albuminoid matter extracted. It is preferred to use a tank with a false bottom, the lime being placed below and the grain above the false bottom, so that they do not actually come into contact.—A. J. K.

XVI.—BREWING, WINES, SPIRITS, Etc.

New Filtering Apparatus for Beer, Wine, etc. Dingl. Polyt. J. **263**, 34—35.

Figs. 1 and 2 illustrate a form of apparatus used for this purpose by Fr. Vanieck. It consists of a number of frames of wire gauze (Fig. 1) placed one above the other, with sheets of filter-paper between each. Each piece of wire "gauze" contains two holes, each bordered by a rim, one rim being perforated and the other not. The filter-papers contain corresponding holes. The frames are placed one above the other in such a way that the perforated and unperforated rims occur alternately, thus forming channels for the inflowing and exit liquor O, O (Fig. 2). A fall of five metres or half an atmosphere pressure is required. By means of such an apparatus containing 40 frames, each 320sq.dm. area, 1750 litres of wort can be filtered in an hour. Instead of filter paper, chemically pure woody fibre may be employed, which can be washed after use. The form of filter-press used is shown in Fig. 3.—A. G. G.

Fig. 1

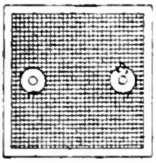

Fig 2

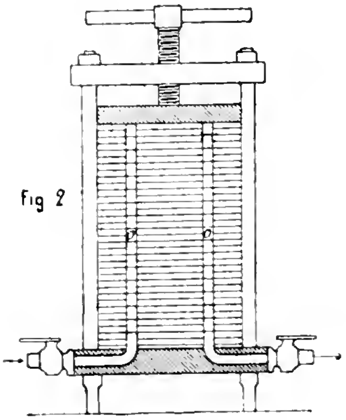

Fig. 3.

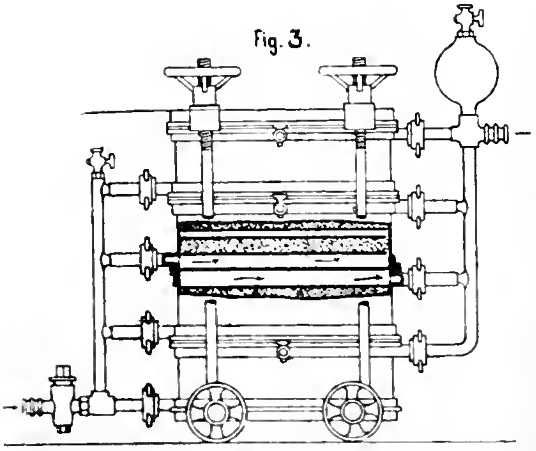


The Limit of Fusel Oil in Spirits. G. Bodländer and J. Traube. Rep. Anal. Chem. **7**, 167—169.

A point of considerable importance is the limit of fusel oil which should occur in brandies and liqueurs. Beer has proposed a standard of 0·3 per cent., but from experiments already published by one of the authors with Traube's capillarimeter (this Journal, 1886, 393, 497, and 547), the authors consider this number too high. From a series of determinations which they have made with the cheapest and most inferior brandies (costing from 30—40pf. per litre), they now fix the maximum limit of fusel oil in spirits at 0·1—0·15 per cent. Only one of the samples examined exceeded Beer's limit, and this was the dearest of all those examined. The determinations were made with the above-named apparatus.

—G. H. M.

Improvements in the Treatment of Brewers' Worts. W. Spencer and J. Jones, West Derby, Lancashire. Eng. Pat. 4168, March 25, 1886. 6d.

The object of this patent is the aëration of worts after they leave the copper. For this purpose the worts are passed through a cage having fine slits over its entire surface, and, at intervals, rims with serrated edges in order to spread the worts over as large a surface as possible. When the worts have drained away the hops remaining in the cage are sparged with boiling water by means of a revolving sparger.—G. H. M.

Improvements in Treating Brewers' Worts. F. Faulkner, Oldbury, and W. Adlam, Bristol. Eng. Pat. 5772, April 28, 1886. 8d.

This patent covers the use of a blast of heated air to the brewers' mash tun (compare Eng. Pat. 4071, 1886; this Journal, 1887, 221) in order to effect the oxidation of the more deleterious nitrogenous substances in the wort. The temperature of the blast of air must not be sufficiently high to injuriously affect the active diastatic substances of the malt extract. The plant required is fully described and illustrated.—G. H. M.

An Apparatus for Pasteurising Beer, Wine, and other Suitable Fluids. H. Schaarwächter, Barmen, Germany. Eng. Pat. 6401, May 12, 1886. 8d.

The inventor claims the use of an apparatus for pasteurising liquids, a description of which would be unintelligible without the details and drawings given in the specification.—G. H. M.

The Application of an Improved Antiseptic Salt in Brewing. A. Boake and F. G. A. Roberts, Stratford, Essex. Eng. Pat. 8420, June 26, 1886. 4d.

This consists of the use of sodium metasulphite, $Na_2SO_3.SO_2$, as an antiseptic in brewing. The salt is used in the proportion of three to six ounces per quarter of malt, or its equivalent.—G. H. M.

XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, Etc.

(A) CHEMISTRY OF FOODS.

American Barley. C. Richardson. Amer. Chem. J. **9**, 16—22.

The author has examined a large number of Canadian and American barleys and compared the results with those given by Maercker, who considers that the characteristics of a good barley are fine colour, mealy consistency, and small amount of albuminoids. The best Canadian barley is grown in the counties north of the north-western part of Lake Ontario, and, as this forms the greater part of the Amercian supply, the United States samples are compared with it. Maercker found that the finest grain contained not more than 8 per cent. of albuminoids, and consisted of at least 80 per cent. of mealy corns. Of the twelve typical specimens of the Canadian crop, none were below 9 per cent. of albuminoids, the average being 9·83, and only six contained 60 per cent. of corns which were mealy or half-mealy in structure. They cannot be said, therefore, to be equal to what is considered extremely fine barley in Germany. They are, however, better than the average production of European countries. In weight per bushel they are about the same or slightly heavier than the average found by Maercker—52 pounds—and in moisture, much dryer than the product of damper climates. Of the different districts, that north of Lake Erie produces the specimens richest in nitrogen, but, on the other hand, the percentage of mealy corns is much higher.

The average of the United States barley is about as mealy as the Canadian average, but out of 64 samples only 2 contained 80 per cent. or over of mealy or half-mealy corns. In weight per bushel there is no variation from Canadian and foreign grain, but in size the barleys of the United States, as a whole, are larger than those of Canada. The average percentage of albuminoids is greater in the United States barley than in Canadian, and much above Maercker's number; the Californian is 1 per cent. lower than the average for the rest of the country, which is 11·5 per cent. In brightness, the samples from those portions of the country having a dry climate at harvest time, especially the Pacific slope and the North-west, were far superior.

It was noticed that winter-sown barley contained less albuminoids than the spring-sown grain; the former gave 10·5 per cent., the latter 11·42. In a few samples the outer covering of the grain was detached and weighed. The extreme amounts were 16·94 and 12·55 per cent., much less than in oats.—G. H. M.

An Improved Baking Powder. H. Watkins, Hereford. Eng. Pat. 5162, April 14, 1886. 4d.

THE special feature of this invention is the substitution of malt flour for the starch or farina ordinarily employed in admixture with other substances for use as a baking powder.—C. C. H.

Improvements in Preserving Milk, and in Vessels or Containers therefor. P. Jensen, London. From K. G. Dahlz, Drammen, Norway. Eng. Pat. 10,903, August 26, 1886. 8d.

THE milk is first strained and cooled down to 10° C. or 15° C. It is then put into cubical vessels having two sides flat and the other two dished; the vessels are previously sterilised by being heated to 150° C., and after being filled with milk are hermetically sealed. The temperature is then raised and kept to 70° C. for 1$\frac{3}{4}$ hours, cooled down to 40° C. for 1$\frac{3}{4}$ hours, and again raised to 70° C.; this is repeated two or three times. Finally the temperature is raised to and kept at 100° C. for half-an-hour, after which it is cooled down to 15° C. By this means it is believed all the organisms, as well as the germs, are quite destroyed; hence whilst not destroying or impairing the fresh taste, the milk so treated will keep fresh for an indefinite period.—C. C. H.

An Improvement in the Preparation of Food Products. C. S. Boynton and W. J. Van Patten, Burlington, Vermont, U.S.A. Eng. Pat. 17,075, Dec. 30, 1886. 4d.

ANY of the cereal grains—*e.g.*, wheat, oats, barley, maize, rice, etc., are decorticated, crushed, and dried at 180° F. To the granulated meal so obtained a solution containing diastase, prepared in the usual way from malted barley, is added, and the whole dried at a temperature from 160° F. to 175° F. Care must be taken to avoid the formation of grape sugar.—C. C. H.

Improvements in the Manufacture of Extract of Coffee. H. F. Von Konitz, Berlin; and J. Tuntz, Bonn. Eng. Pat. 122, Jan. 4, 1887. 4d.

AN infusion of coffee berries is evaporated to a syrupy consistency; the vapour passing off is condensed and subsequently distilled in vacuo after the addition of a sufficient quantity of a non-volatile acid to render it slightly acid. The first part of the distillate, amounting to about one-fourth of the whole, contains the aromatic flavouring of the coffee berries: when this is added to the syrup first prepared a substance is obtained which on mixture with water gives an admirable imitation of freshly prepared coffee.—C. C. H.

Improvements in the Process of and Apparatus for Manufacturing Powdered Milk. John Carnick, New York, U.S.A. Eng. Pat. 1996, Feb. 8, 1887. 8d.

THE author has succeeded in preparing on a commercial scale a cream-white, dry, powdered or granulated milk, free from stickiness or lumps, of a pleasant sweet milky flavour, and of good keeping qualities. Fresh cows' milk, from which about $\frac{1}{4}$ to $\frac{1}{3}$ of the cream has been previously removed, is evaporated in a vacuum pan at a temperature of 140° F. to 160° F. to the consistency of a thick syrup. At this stage granulated cane sugar is added in a continuous stream, the whole being kept constantly agitated and the temperature reduced to from 120—130° F. At this temperature no caramel is formed, nor discolouration takes place, and the produce of the sugar causes the whole mass to remain granular and finally to dry up to a friable white mass, which is easily removed and ground to a fine powder, in which form it is usually sold and will keep for a long time. The evaporation is conducted in a horizontal cylindrical copper vacuum pan provided with pumps and condenser, and suitable agitating apparatus, and covered with a jacket into which can be turned hot or cold water or steam, so that any desired temperature may be regularly maintained. The finished product may be sold in various forms, either pure or in combination with coffee, chocolate, cocoa, etc. The sugar used is in the proportion of from 30 to 50 per cent. of the batch of milk treated.—A. J. K.

(*B*) SANITARY CHEMISTRY.

Subterranean Motion of Coal-Gas in the Direction of Heated Dwellings. A. Wagner. Rep. Anal. Chem. **7**, 131—138.

IN 1884 the author published an investigation into the question of poisoning by coal-gas, in which it was asserted that with gas escaping from broken pipes the aspiratory action of heated dwellings is only brought to bear for a comparatively short distance, and that in the case of hermetical coverings—as, for instance, asphalt paving—the gas takes the course which offers the least resistance to its passage. This assertion has been subjected to a severe criticism by Pettenkofer and Sudakoff in the *Archiv für Hygiene*, 1886, 166. Against the strictures of the latter the author enters a strong protest.—D. B.

Improvements in the Formation of Organic Oxides, and in the Oxidation of Matter Suspended and Dissolved in Liquids. J. G. Lorrain, London. Eng. Pat. 3826, March 18, 1886. 6d.

THE patentee proceeds by one of two methods: (1) by placing "a quantity of catalytic material" in the liquid, and forcing air through so as to effect chemical combination between the oxygen of the air and the oxidisable matter of the liquid; (2) by similarly suspending or immersing "a quantity of catalytic material" in the liquid, and then decomposing the water of the liquid electrically, either by a dynamo or other means.—C. C. H.

Improvements in the Preparation of Materials for Use in the Treatment of Sewage and Foul Water. J. W. Slater, London, S. K. Page, Aylesbury, W. Stevens and The Native Guano Company, Ltd., London. Eng. Pat. 3973, March 20, 1886. 6d.

This specification relates to the preparation of sulphate or chloride of manganese, alone or mixed with the sulphate or chloride of alumina for the purpose described. In the preparation of the sulphate the patentees take 36 parts of sulphur, 100 parts of manganese dioxide, and place them in a covered crucible, the sulphur at the bottom; the whole is then maintained at a dull red heat for three to four hours; a crude sulphate of manganese suitable for the purpose specified is the result. The chloride is similarly prepared by heating together in a crucible 36 parts sulphur, 300 parts common salt, 100 parts di-oxide of manganese. When it is desired to prepare the mixed sulphates and chlorides of manganese and alumina, bauxite, ground blast-furnace slag or alum clay, 40 parts of either to 10 of the di-oxide of manganese is introduced into the mixture prior to the application of heat.—C. C. H.

Improvements in the Purification and Utilisation of Sewage, and Apparatus therefor. L. G. G. Daudenart, Brussels. Eng. Pat. 4203, March 25, 1886. 11d.

The patentee describes a system of sewage treatment by means of defecation by lime, succeeded by the addition of salts of alumina and chloride of zinc. Settlement is effected in tanks shaped in section like those usual in this country; the sludge is continuously withdrawn by an endless screw and run on to land. The effluent is conducted away in large carriers to land, upon which it is pumped for purposes of irrigation.
—C. C. H.

Improvements in or connected with Filter-presses, and in the Drying of Sewage Sludge and other Moist Matters. W. F. B. Massey-Mainwaring, London. Eng. Pat. 4878, April 7, 1886. 11d.

The filtering faces of the chambers of the filter-press are made flat, and covered with a perforated cast-iron plate resting thereon and bearing upon the chamber by bosses or projections so as to afford a good drainage. The bosses or projections are sometimes replaced by grooves or furrows. The outlets from the chambers are fitted with a three-way cock, so that when the chambers are full a current of air, sometimes heated, may be drawn or forced through to facilitate the removal of moisture from the pressed cake.—C. C. H.

Improvements connected with the Deposition of Finely-divided Solid Matter floating or suspended in Air or Gases. J. G. Lorrain, London. Eng. Pat. 6495, May 14, 1886. 6d.

Guitard and Lodge have both shown that fine particles of solid matter suspended in the atmosphere can be precipitated by the passage there through of an electric discharge from an electrostatic machine. In the present instance, the patentee makes use of a dynamo-electric discharge, generated as a secondary current in an induction coil by means of a current from a dynamo or a primary or secondary battery. The air or gas is passed through a closed receptacle containing discharging surfaces of netting gauze or plates placed close together, and in connection with the secondary coil of the induction arrangement.—C. C. H.

Improvements in the Treatment of Sewage Sludge and the Preparation of a Manure therefrom. T. H. Cobley, Dunstable. Eng. Pat. 6732, May 19, 1886. 6d.

The pressed cake resulting from the treatment of sewage sludge in filter presses is incinerated; native salts of magnesium, potassium, and sodium are added during the process of incineration to "retain" the ammoniacal fumes given off. The ash resulting from such incineration is used instead of caustic lime for the purpose of rendering a fresh quantity of sludge pressable. The resulting ash is richer as a manure than an ash resulting from the addition of caustic lime to the sludge. Peat, shoddy, or wool dust are also sometimes used to retain the ammoniacal fumes during the process of incineration.
—C. C. H.

An Improved Deodorant and Disinfectant. H. M. Caldwell, Sydney, New South Wales. Eng. Pat. 6966, May 24, 1886. 4d.

The improved compound is prepared by first mixing 7cwt. of ferrous sulphate with 40lb. peroxide of manganese; 400 gallons of water are added, and the whole boiled for three hours, adding whilst hot 6lbs. oil of eucalyptus; this preparation acts as a deodorant. Four tons of caustic soda are heated to a dull red with one ton peroxide of manganese for a period of 48 hours; water is subsequently added and re-evaporated. This second preparation is added to one half that first described, the mixture forming a powerful deodorant and disinfectant.—C. C. H.

Improved Manufacture of Disinfecting Powder. J. W. Knights and W. D. Gall, Cambridge. Eng. Pat. 11,011, August 28, 1886. 4d.

Ground and dried peat is mixed with an antiseptic such as sanitas, creosote, or carbolic acid.—C. C. H.

Improvements in the Manufacture of Materials for Use in the Treatment of Sewage, etc., etc. F. Candy, Bexley. Eng. Pat. 13,829, Oct. 28, 1886. 6d.

Any iron ore containing alumina, lime, and magnesia is mixed with carbonaceous material and carbonised in closed retorts in the usual manner. The resulting product is treated with sulphuric or hydrochloric acid. The quantity of acid used is such that the mixture when cool becomes a cake or semi-dry mass. The patentee terms the product "magnetic precipitant," and uses it for the purification of sewage or other polluted waters.
—C. C. H.

Improvements relating to the Purification of Sewage. J. Wohanka and K. Kocian, Prague. Eng. Pat. 278, Jan. 8, 1887. 4d.

The sewage is first treated with ferrous sulphate prepared by treating rich ochre-brown iron ore with sulphuric acid; fresh milk of lime is then added, and finally, an aqueous solution of water-glass. The sludge from such a process of treatment is separated by subsidence in the usual manner. The effluent is run into a separate set of tanks, and further purified by the injection of smoke or gases from chimney shafts or flues. The patentees state this destroys the organism causing putrefactive fermentation. The effluent from this treatment is finally filtered through a bed of gravel, coke, ashes, etc., or other porous material.—C. C. H.

(C.) DISINFECTANTS.

The Manufacture of Bromine Preparations for Sanitary and other Purposes. W. D. Borland, London. Eng. Pat. 6191, May 7, 1886. 6d.

A mixture is made of a soluble bromide with a soluble bromate, preferably of sodium or potassium, and this is mixed intimately with an alkaline bisulphate, such as sodium hydrogen sulphate. For a less concentrated form, nitre-cake is used instead of pure bisulphate. For sanitary purposes it is sometimes convenient to add other substances, such as cupric sulphate, alum, etc. The addition of a small amount of a terpene, essential oil, camphor or hydrocarbon, increases the keeping power of the preparations.—B. T.

XVIII.—ELECTRO-CHEMISTRY.

On the Distillation and Electrolytic Treatment of Zinc Scum. B. Rosing. Zeits für Berg. Hütten. u. Salinenwesen. Dingl. Polyt. J. **263**, 87—94.

SEE page 370.

Improvements in, or connected with, Electrical Batteries and Appliances therefor. A. W. Armstrong, Lewisham. Eng. Pat. 5971, May 3, 1886. 8d.

THE porous cells of this battery are made either of clay or carbon, or a mixture of both, and are packed with granulated carbon. Three tubes pass into each cell, which is then covered with an air-tight seal. By a special arrangement, a measured quantity of the excitant passes from a tank into the porous cells by one of the tubes before mentioned. A supply of water, the amount of which can be regulated according to the work the battery has to do, passes from an ordinary water-cistern into an outer vessel containing the soluble electrode; this water can be made to pass through a vessel containing any suitable soluble substance for promoting greater activity in the battery. When the battery is working, gas is generated in the porous cell and forces some of the partially spent liquid into a reviving tank, from which tank fresh liquid passes back by the third tube. The zinc plate in the outer cell dips into mercury, which serves as an electrical connection, and also to keep the plate amalgamated. A brush is fitted, and can be raised or lowered in order to remove any insoluble salts from the surface of the zinc.—B. T.

Improvements in the Manufacture of Carbon Electrodes. R. Applegarth, London. Eng. Pat. 9518, July 22, 1886. 8d.

THESE electrodes are moulded from suitable carbon paste, which may contain a proportionate amount of manganese rich in oxygen, into the form of vessels with the inner surface corrugated, so as to present a large extent of surface to the exciting medium. The upper part of the cell has a metal band secured to it.—B. T.

Improvements in the Preparation of Carbon Filaments for Electric Lighting. H. J. Haddan, London. From C. Seel, Charlottenburg, Germany. Eng. Pat. 6203, May 7, 1886. 8d.

VEGETABLE FIBRE is steeped in a solution of mineral salts and a gum consisting of a silicate, gum senegal, and caustic soda; it is then rolled into the shape of angle iron and carbonised in any well-known way. The charcoal thread is placed in a box, and melted paraffin wax poured round it, the two ends of the thread projecting through the cover. When the wax is solid, a current of electricity is sent through the carbon until it attains the required resistance. It is then cleaned from paraffin and is ready for use in the lamp.—B. T.

Improvements in the Process of, and Apparatus for, Manufacturing Carbons for Electric Lamps. J. T. Lister, Cleveland, Ohio, U.S.A. Eng. Pat. 10,800, Aug. 24, 1886. 1s. 1d.

THIS patent has for its object the substitution of special machinery for the manual processes now generally adopted in the making of carbons. The mould is made in two parts, the lower of which is placed horizontally on a car which is run on rails underneath the filler. This consists of a vessel in which a cylindrical screen is kept revolving. The mixed dust of which the carbons are to be made is thrown into the middle of this, and eventually all passes through it on to a worm, also kept revolving, which conveys it to the delivery spout. This is provided with as many partitions as there are grooves for carbons in the mould. The dust, now thoroughly mixed by the processes it has lately gone through, passes from the delivery spout into the mould as soon as the latter is placed in position; this delivery is automatically performed by the upward movement of a ram to be described hereafter. The mould is now rolled from the filler, and the top having been put on, is passed into a furnace. Having been baked sufficiently, it passes on to a turntable, and is brought in its turn under the action of a hydraulic press. The ram, in rising, compresses strongly the carbons, and at the same time operates the filler. In falling, the turntable is revolved, and the same series of operations repeated automatically on another mould. The carbons are now removed in such a way that they cannot possibly be bent, and the webs joining them separated by revolving cutters, leaving the carbons quite round and smooth. The car is wheeled on till the ends, which have been made to project, come in contact with revolving knives, and are thus pointed. These carbons can be made cheaper, straighter, and of more uniform density than those produced by manual processes.—E. T.

Improvements in Primary Batteries. M. Bailey and J. Warner, London. Eng. Pat. 13,592, Oct. 23, 1886. 8d.

FINELY-GROUND plumbago is incorporated with nitric or "oxacid," and packed with a suitable carbon electrode in either the outer or porous cell of a battery. Zinc is used for the other electrode. The carbon is sometimes of a tubular form, and when embedded in the paste, has its interior filled with the acid. To re-charge, fresh acid is poured into the tube, or the spent paste replaced by new. —E. T.

An Improved Method of Preventing the Escape of Noxious Fumes from Batteries used for Electrical Purposes. M. Bailey and J. Warner, London. Eng. Pat. 14,937, Nov. 17, 1886. 8d.

THE internal pot of the battery, containing the fuming acid, is closed by a suitable stopper, through which passes vertically a thin glass tube. The part of this outside the cell is sealed into the bottom of a much wider glass tube, in such a way that, passing up the inside of the latter, it ends a little below the top of the wider tube. A third tube, with sealed top, fits loosely inside the large one. Water or other suitable liquid being poured in, the whole forms a small gasometer. In some cases the upper part of the porous pot is narrowed as in an ordinary bottle, and this upper portion glazed.—E. T.

Improvements in an Electrolyte, and Depolarising Solution for Voltaic Batteries. W. C. Quinby, San Francisco, Cal., U.S.A. Eng. Pat. 111, Jan. 4, 1887. 6d.

THE electrolyte which the inventor employs consists o the anhydrous sulphate of the sesquioxide of iron, dissolved in water or other equivalent liquid. This sulphate is found as a natural formation known as "coquimbite." This natural salt is used as the new electrolyte in either a one-fluid or a two-fluid cell, in the latter case the insoluble electrode being in contact with coquimbite. During the working of the cell, sesquioxide of iron is formed and precipitated, and if this precipitate be treated with sulphuric acid, it can again be used as an electrolyte. —B. T.

Improved Apparatus for Preventing the Escape of Noxious Fumes or other Gases from Primary, Secondary, Gas, or other Batteries used for Electrical Purposes. M. Bailey and J. Warner, London. Eng. Pat. 1656, Feb. 2, 1887. 8d.

IN this method the fumes from the cells are collected in a glass bell-jar completely covering the cell, and with its lower edge dipping into some liquid, so as to form a secure seal, or a lip is fitted to the top of existing cells, and the bell-jar dips into this lip. There is an opening fitted with a stop-cock in the top of the glass, by which the contained gases may be liberated.—B. T.

Improvements relating to the Electro Deposition of Aluminium, and to Apparatus therefor. H. H. Lake, London. From Count R. de Montgelas, Philadelphia, U.S.A. Eng. Pat. 1750, Feb. 3, 1887. 6d.

ALUMINA is dissolved in hydrochloric acid, and the solution evaporated to obtain the dry salt, which is then dissolved in hot water. A vessel is made with two compartments, separated by a porous partition. The above solution is poured into one, and common salt into the other. A current is passed from one into the other, entering at the common salt, by suitable electrodes, until the solution of the aluminium salt becomes colourless. The double chloride of aluminium and sodium thus formed is evaporated to dryness and redissolved, to get rid of excess of acetous matter. This solution, kept neutral, is used as the plating liquid with an aluminium anode.—E. T.

Improvements relating to Electric Batteries. H. H. Lake, London. From Count R. de Montgelas, Philadelphia, U.S.A. Eng. Pat. 1752, Feb. 3, 1887. 6d.

A GROOVE is formed along the lower side of a small square bar of wood. In this is placed the upper edge of a perforated plate of aluminium, which forms the negative electrode. A screwed bolt attached to the latter passes through the bar and is held by a binding screw at the top. On each side of the wooden supporting bar are clamped zinc plates by aluminium bolts, connection being made by aluminium terminals. The battery resembles in appearance that of Smee. Any suitable exciting liquid may be used.—E. T.

XIX.—PAPER, Etc.

Improvements in the Manufacture of Water and Fireproof Papers, Millboard, and similar Materials. W. E. Heys, Manchester. From E. G. H. Ladewig, Rathenon, Germany. Eng. Pat. 5563, April 22, 1886. 6d.

THE paper, millboard or similar substance used in carrying out this invention may be used alone or in combination with layers of cork, straw, wire-gauze or any such substances. The pulp is chiefly composed of asbestos, treated with chloride of sodium or glycerine to preserve the flexibility and other peculiar properties of the asbestos. 100 parts of asbestos require about 4 to 6 parts of glycerine diluted with 5 to 10 parts of water. From 4 to 6 parts of isinglass may with advantage be mixed with the water used for diluting the glycerine.

The impregnated asbestos is then pulped in a suitable rag-engine and reduced with water as required. The addition is now made of 2 to 3 parts of dry resin soap dissolved in water, 6 parts of zinc chloride in 15 to 25 parts of water, and 10 parts of graphite with about 50 parts of water. The latter addition increases the resistance of the finished product to the action of fire. If required for pipe joints, it may be provided with wire-gauze on one or both sides. When rolled or formed into sheets, the material is air-dried, immersed in a 1 per cent. solution of zinc chloride, and dried. Finally the sheets are passed through a solution of resin soap and water to which has been added ½ to 1 per cent. of soap, the resin soap having been dissolved in spirit and added to the water. It is claimed that material prepared as described is capable of resisting any ordinary degree of heat, and also that it is suited, owing to its elasticity, etc., for packing steam-joints and for other purposes where the combined action of heat and water have to be resisted.—H. A. R.

An Improved Process for Manufacturing Composition from Cellulose or Ground Wood, which can be given any desired form by employing heat and pressure. R. Eisenhaut, Pyritz, Germany. Eng. Pat. 1443, Jan. 29, 1887. 4d.

THE following is the substance of the claim made by this inventor: a process for manufacturing a composition which can be given any desired form by saturating cellulose or ground wood with a solution of gum in hot water and ammonia, drying the same more or less, and subjecting the said composition to the influence of a mixture of ammonia gas and steam under pressure.

The product so obtained may be shaped as desired by hot plates, dies, or other suitable means. If required, the composition may be tinted by the addition of colours in the state of dry powder, or else, before or during the manufacture, with organic colours.

—H. A. R.

Improvements in Machinery for the Manufacture of Paper Pulp. H. H. Lake, London. From F. J. Marshall, Mass., U.S.A. Eng. Pat. 1808, Feb. 4, 1887. 8d.

THE main features of this invention are as follow: (1.) The combination of fixed and revolving discs in combination with the conical engine commonly in use. (2.) A worm and gear in combination with screw threaded collars for moving the bed-plate to and fro.

—H. A. R.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Extraction of a New Acid from the Leaves of Gymnema Sylvestre. Nature, **1887**, 565—567.

THIS is an abstract of a paper read before the Nilgiri Natural History Society, Ootacamund, India, by David Hooper, F.C.S., March 7, 1887. It was found that on chewing the leaves of this asclepiadaceous plant, which grows in the Deccan Peninsula, Assam, and Africa, immediately afterwards all appreciation of the sweet taste of sugar is lost. If ginger-bread were eaten, only the taste of the ginger was perceived; if a sweet orange, only the acid flavour of the citric acid, and the orange seemed as sour as a lime. Bitterness is also destroyed, and sulphate of quinine tastes merely like chalk. The effect lasts one to two hours. The principle appears to be soluble in water, alcohol, ether and benzene. The ethereal extract consisted of chlorophyll and two resins, separable by their different solubilities in alcohol. Both resins are of an acrid nature, and left a tingling sensation in the throat. The aqueous solution of the substances soluble in alcohol had a decided acid reaction. This solution was precipitated by sulphuric acid, was collected on a filter, and washed free from sulphuric acid, when a greenish powder was obtained insoluble in water, but soluble in alcohol, ether, benzene, and chloroform. With potash, soda, and ammonia, it afforded a fine red solution with orange coloured froth, precipitated in the case of either of the resins by mineral acids. The substance has the characteristics of an organic acid somewhat similar to chrysophanic acid, but possessed of some very peculiar reactions, and possessing also the anti-saccharine property ascribed to the leaves. It is termed by Hooper *Gymnemic acid*, and this acid constitutes more than 6 per cent. of the constituents of Gymnema leaves in combination with a base not yet isolated. The following analysis was given of the powdered and sun-dried leaves:—Ether extract (chlorophyll and resins) 5·51, alcoholic extract (gymnemic acid, tartaric acid, glucose, neutral bitter principle, resin, &c.) 19·50, aqueous extract (gum 1·45 per cent, glucose, carbohydrate and extractive) 16·87, alkaline extract, by difference (albuminous and colouring matters) 8·15, acid solution (calcium oxalate, 7·64, pararabin 2·74), ash (balance of) 5·69, cellulose 27·86, and moisture 6·04 per cent.; total, 100·00.—W. S.

Arginine. E. Schulze and E. Steiger. Zeit. f. Phys. Chem. **11**, 1.

ON treating the aqueous extract of the germinated seeds of *Lupinus luteus* with phosphor-tungstic acid, having previously removed all albuminous substances, a copious white precipitate is obtained, from which the authors isolated a nitrogenous base called arginine, $C_6H_{14}N_4O_2$. It forms crystalline salts, and is somewhat similar in its properties to creatinine.—D. B.

Crystalline Substances from "Kamala." L. Jawein. Ber. 20, 182—183.

KAMALA is a colouring matter used in the East Indies, and prepared from the seed capsules of *Rottlera tinctoria Roxb.* Anderson (*Jahresber.* 1855, 669) obtained a crystalline substance from kamala which he named Rottlerin. The author has also prepared a substance by extracting the crude kamala powder with carbon bisulphide, which agrees in its reactions with that of Anderson, but does not give analytical numbers corresponding with the formula assigned to it by the latter. (Compare A. G. Perkin and W. H. Perkin, Jun., *Ber.* 19, 3109).—G. H. M.

Action of Hydrogen Peroxide on Albumen. C. Wurster. Ber. 20, 263—267.

WHEN unfiltered white of egg is mixed with an equal volume of hydrogen peroxide, the mixture well shaken, and, for every 100cc. of the former, 1—2cc. commercial lactic acid and 1—2grms. sodium chloride or 20cc. of a 5 per cent. solution of this salt added, the mixture becomes turbid, and after a longer or shorter time, depending upon the temperature, sets to a solid, coagulated, cheese-like mass. Water is added, and the substance quickly filtered off; it always retains, even after prolonged washing, hydrogen peroxide and lactic acid. The filtrate from the precipitated albuminoid evaporated to a syrup gives the reactions for peptone, which however is only present in small quantity. The precipitated albuminoid is quickly peptonised by pepsin and hydrochloric acid. The above results do not agree with those of Chandelon on the action of hydrogen peroxide on albumen (this Journal, 1885, 748). The author ascribes this to the different methods in which the hydrogen peroxide was employed.—G. H. M.

Hydrastine. J. F. Eijkman. Chem. Zeit. Rep. 11, 22.

IN a previous communication (this Journal, 1886, 677) Freund and Will gave analyses of hydrastine confirming the formula $C_{22}H_{23}NO_6$, ascribed to this compound by Mahla. The author's analysis, however, gave numbers agreeing with the formula $C_{21}H_{21}NO_6$.* The statement that hydrastine yields opianic acid and a base on treatment with dilute nitric acid is confirmed by the author, the reaction being represented by the equation :—

$$C_{21}H_{21}NO_6 + H_2O + O = C_{11}H_{13}NO_3 + C_{10}H_{10}O_5.$$

—D. B.

The Alkaloid Tulipin. M. A. Nicot. Les. Nouv. Remèd, 1886, 519.

THE alkaloid obtained by Gerrard from *Tulipa Gesneriana*, and which occurs in considerable quantities in all parts of the plant, appears from the author's researches to exert the action of colchicine, of scillitine, of veratrine and even of strychnine. Its formula is not yet determined. A dose of 0·02grm. is sufficient to kill a frog; 0·1grm. suffices to kill a cat, death ensuing from paralysis of the heart. The alkaloid appears to act very energetically upon the nervous system. Applied medicinally in quantity of ·005—·006grm., in 24 hours it increases the salivary flow, and acts as a diuretic and aperient.—W. D. B.

On Strophanthus. H. Helbing. Pharm. Ztg. 1887, 37.

THE seeds, which amount to 37·4 per cent. of the weight of the drug, contain 24 per cent. of fatty oil, 26·52 per cent. of extract (by the dilute spirit of the Pharmacopœia), and 49·38 per cent. of residue. The oil has a dark green colour with slight red fluorescence, and imparts an emerald green tint to its ethereal solution; it is somewhat thick at the normal temperature, and has a specific gravity of 0·925 at 15° C. Strophanthin may be extracted from the seeds by digestion with alcohol. This extract after dilution with water is freed from fatty matter by agitation with ether, the latter being then removed by a separating funnel. The aqueous solution is treated first with basic lead acetate, then with hydrogen sulphide and filtered, purified by animal charcoal, and carefully evaporated. The residue, which amounts to 8·57 per cent. of the weight of the original seeds, is nearly colourless, but dissolves in sulphuric acid (concentrated or dilute) to a dark green solution, afterwards changing to dark red. Alkaloid reagents give no reaction. It is readily soluble in water and alcohol, but insoluble in ether, petroleum ether, and chloroform.—W. G. M.

On Strophanthus. Wm. Elborne. Pharm. J. March 12, 1887.

THE author, after referring to the pharmacy of the various parts of the fruit or pod, showed that the weight of the seed was 42 per cent.; hairs, 25 per cent.; endocarp, 25 per cent. The seeds on analysis were found to consist of—

(1.) 20·8 per cent. of petroleum ether extract, a yellowish-green fixed oil, not bitter, giving a brown colour when warmed with sulphuric acid and potassium bichromate On standing, crystals separated, which burned like sulphur and left no residue.

(2.) 0·9 per cent. of absolute ether extract, a fatty substance of a green colour.

(3.) 1·5 per cent. of absolute alcohol extract, a bitter residue, resembling the glucosides and giving no alkaloid reactions.

(4.) 2·9 per cent. of aqueous extract containing the same bitter principle found in 3.

(5.) 19·6 per cent. of albuminoid matter; this large proportion rendered the separation of the bitter principle more difficult.

(6.) 54·3 per cent. of insoluble matter. See also preceding abstract.—O. H.

On Vegetable Organisms in Solutions of Alkaloids. L. Soubriran. Journ. Pharm. Chim. 1887, 69.

FOR preventing the formation of the organisms, which render alkaloid solutions turbid, an addition of boric or salicylic acid has been recommended; but Professor E. B. Stuart prefers to use for this purpose camphorated spirit diluted with an equal weight of water, by which equally good effects are produced unattended by any disadvantages. One two-thousandth part of camphor should be used for all alkaloids excepting atropine sulphate, for which saturated camphorated spirit should be employed. The growth of organisms in solutions of neutral citrates, malates, and tartrates may be similarly hindered, but not entirely prevented.—W. G. M.

On Spiritus Aetheris Nitrosi and the Recovery of Oxalic Acid from its Distillation Residue. H. Frickhinger. Arch. Pharm. 1886, 1065.

FOR the preparation of this body the Pharmacopœia Germ. recommends the distillation of 4 parts of alcohol (0·832 sp. gr.) with 1 part of nitric acid (1·185 sp. gr.); the distillate to be then neutralised with calcined magnesia, and rectified on the water-bath. The author recommends the use of alcohol of 0·812 sp. gr., since nearly the whole mixture may then be distilled over, and the distillate will contain less free acid. The preparation is best conducted on a sand bath, in a retort accurately jointed to a well cooled receiver, having at its extremity a glass tube bent twice at right angles, leading into a narrow mouthed bottle, also thoroughly cooled. To test the distillate in the receiver, the cooling is discontinued until, by the increasing pressure in the apparatus, it is driven forward into the test vessel. The liquid will then require rectification. From the residue of the first distillation, oxalic acid can be obtained by pouring it into nitric acid of 1·35

---

* In a recent paper (Ber. 20, 80) Freund and Will substituted the formula $C_{21}H_{21}NO_6$ for that previously ascribed to hydrastine.—D. B.

sp. gr. (contained in a large vessel on account of the violent action which may set in), and allowing it to stand for a fortnight; the crystals by that time deposited may be purified by re-crystallisation.—W. G. M.

On the Presence of Arsenic in Chloroform. L. Scholvien. Apoth. Ztg. 1887, 14.

THE author has recently found that with many samples of chloroform, silver nitrate produced, after a short time, a dark-brown turbidity, which could be removed by nitric acid, and which did not form at all if the solution contained a little nitric acid from the first; this has been traced to the presence of arsenic in the chloroform. As a test for this impurity, the chloroform is to be stirred with dilute potash, evaporated, and the residue tested by Marsh's or Bettendorf's methods. When distilled, the arsenic remains in the residue, none passing into the distillate. The presence of the arsenic may originate from the use of an arsenical chloride of lime, which, with the alcohol, might form arsenical organic compounds that would first distil over with the chloroform, yet not be capable of distillation from the chloroform itself. Or it may be due to the use of impure sulphuric acid. It would be interesting to ascertain whether any of the disagreeable effects experienced after inhalation of some samples of the anæsthetic could be traced to the presence of this objectionable impurity.—W. G. M.

An Improved Process for the Complete Purification of Perfumes, in the Manufacture of which Sulphuret of Carbon has been used. E. Edwards, London. From E. A. Viteau, Paris, France. Eng. Pat. 5936, May 1, 1886. 6d.

PERFUME, obtained in the usual way by carbon bisulphide, is evaporated to dryness, and the carbon bisulphide removed by a current of pure hydrogen gas. The product is put into a sealed vessel, and enough pure alcohol added to keep the product in a semi-fluid state. The vessel is then heated sufficiently to make its contents perfectly fluid, and it is agitated until the perfumed product and alcohol are thoroughly mixed. The remaining carbon bisulphide passes off as sulphuretted hydrogen when the vessel is opened, and in order to get rid of all traces of this gas, pure warm hydrogen is passed through the liquid, and very finely-divided silver introduced. The perfume is then separated out by washing with alcohol and submitting to refrigeration at a low temperature.

—B. T.

An Improved Method of Mixing Chloroform with Water. C. E. Landon, Aston; and J. Wilson, Birmingham. Eng. Pat. 6588, May 17, 1886. 4d.

To make chloroform mix with water, it is shaken up with suitable proportions of saponine and water, an emulsion being at once formed, which settles to the bottom. This will mix with water in any proportions.—E. T.

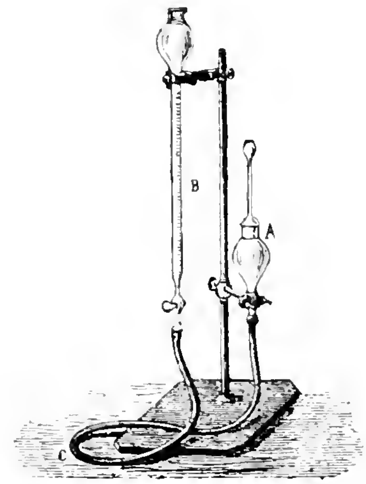
Improvements in the Extraction of Perfume Essences. C. D. Abel, London. From La Société Anonyme des Parfums Naturels de Cannes, Paris, France. Eng. Pat. 6259, May 8, 1887. 8d.

THE vegetable matter to be treated is heated with water in an alembic, and the resulting vapour passed into a condenser of such a sort that any liquid condensed in it will flow back into the alembic. By this means a great deal of the superfluous water is got rid off. In a second condenser the remaining water and essence are all condensed, and flow into a vessel, in which by their different densities they separate. By a pipe attached near the bottom, and bent upwards, the water flows away after a certain level has been reached.—E. T.

XXII.—GENERAL ANALYTICAL CHEMISTRY.

Apparatus for the Estimation of the Specific Gravity of Solids. L. Brasse and E. Vlasto. Génie civil, 1886—1887, 16.

THE funnel A with capillary stopper is connected by an indiarubber tube C, with the small burette B, of about 10cc. capacity. Water or other suitable liquid is poured into the apparatus, so that the surface stands at a low division of the scale in B and at a mark in the capillary part of A. The funnel is now raised and a known weight of the solid is put into it, after which it is lowered until the surface of the liquid again reaches the mark in the stopper. The increase of volume in the burette gives the volume of the substance added, which divided into the weight gives the specific gravity. The method is very expeditious, but greater accuracy than ¼ per cent. is not claimed for it.—A. G. G.



A Delivery Tube for Burettes. W. Leybold. Zeits. Anal. Chem. 26, 230.

MANY chemists prefer to use a glass rod or glass bead for closing burettes, instead of a clip. The glass rod can easily be combined with the delivery tube, as shown in sketch. One end of the glass tube is closed by the blowpipe, and over the other end a piece of indiarubber tubing is slipped. A small flame is directed against the tube at about 1cm. from the closed end; and by blowing through the rubber tubing, a hole is produced at this point; the glass at the edge of the hole is carefully filed off, and the delivery tube is now drawn out to a point. The tube should always be kept in the same position, so as to know on which side the hole is. The author has used such

delivery tubes for some time, and finds that they close tightly, are easy to work with, and retain no air bubbles.
—D. E. J.

Apparatus for the Preparation of Gases for Gasometric Analyses. Alex. Ehrenberg. Zeits. Anal. Chem. **26**, 226—230.

THERE are several objections to Bunsen's well-known apparatus for preparing hydrogen electrolytically; the liquid has to be frequently renewed, on account of the formation of a concentrated solution of zinc sulphate; and zinc is deposited at the negative electrode so rapidly that it sometimes forms a connection between the two electrodes. The apparatus described in this paper, and shown in Figs. 1, 2, and 3, can be used for preparing electrolytic gas, or oxygen or hydrogen separately. It is supported by a heavy foot, and can be raised or lowered as required to suit the level of the mercury in the mercury trough. The vessel *a* is made by cutting off the bottom and part of the neck of a flask, and is tightly closed above and below by ebonite plates. The conducting wires, and also the tube *d*, furnished with a stopcock, pass through the lower plate, the wires being connected with three platinum plates, which serve as electrodes. The wires are covered with guttapercha up to the point where they meet the electrodes, and below the plate they are connected with three spirals of covered copper wire, which lead either to these binding screws or to a commutator. Dilute sulphuric acid (1 : 10) is the fluid used, and in order to fill the vessel, the two tubes, *c* and *c*¹ are removed, and the stopper is taken out of the tube *g*, so as to allow the air to escape; the tubes *b* and *b*¹ are then filled to the required height. The leading tubes, *c* and *c*¹ have the same shape as in Bunsen's apparatus, and the bulbs blown on them are filled with concentrated sulphuric acid. If the binding screw *h* is connected with the positive pole of a battery, and *k* with the negative pole, oxygen gas will collect in *b*, and hydrogen in *b*¹; and these gases can be collected over mercury contained in a trough, into which the tubes *c* and *c*¹ respectively dip. If now, while *k* still remains connected with the negative pole of the battery, the positive pole is connected with the binding screw *i*, *b*¹ will become filled with electrolytic gases (H_2+O), which can be led off by the tube *c*¹; when this is done othe ther tube (*c*) must be closed by means of a glass rod, and a piece of indiarubber tubing *l*. In order to clear or refill the vessel *a*, *b* and *b*¹ must be removed, and the stop-cock *d* opened; the acid can then be run off into a beaker placed beneath. If *b*¹ is graduated into cubic centimetres, the apparatus can be used as a voltameter. The upper part of *b*¹ is then closed by a glass stopper, and after the evolution of the mixed gases, the liquid is allowed to run out through *d*, until it stands at the same level in *b* and *b*¹.—D. E. J.

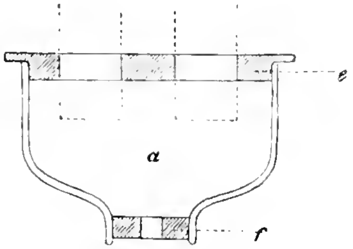

Fig 3.

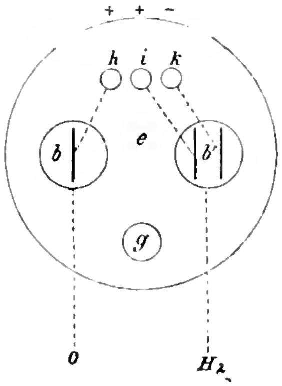

Certain Improvements in Hydrometers and Saccharometers. T. Derham, Bolton. Eng. Pat. 1938, Feb. 10, 1886. 6d.

THE improved hydrometers are so constructed that each poise possesses a specific gravity bearing a definite relation to the initial specific gravity of the series of specific gravities to be indicated by the instrument.
—C. C. H.

Manganese in Steel and Iron. H. C. Babbitt. Amer. Chem. J. **9**, 58—60.

IT has been objected to the author's method of determining manganese in steel and iron by means of the oxidation of the manganese to permanganic acid by the action of lead peroxide in a nitric acid solution, that the presence of lead nitrate and the time of boiling have a great influence upon the accuracy of the results. The author now employs red lead in place of the peroxide, and he quotes the following experiments to prove that the above-mentioned objections are groundless:—

A sample of steel containing 0·5 per cent. carbon, 0·04 silicon, and 0·09 phosphorus, was selected, and the manganese carefully estimated by the sodium acetate and bromine method, which gave 0·515 per cent. manganese. Estimations by the author's method were made as follows: In each case 0·5grm. of steel was dissolved in about 15cc. nitric acid (1·15 to 1·20 sp. gr.), in a 50cc. beaker. The solutions were boiled till nitrous fumes ceased and red lead added—in A, 1grm.; in B, 2grms. The solutions were then diluted to about 30cc. with hot water. In No. 1, the solution was simply stirred after the addition of water: in No. 2, heated to boiling; No. 3, boiled for one minute: No. 4, for two and a half minutes; No. 5, five minutes; No. 6, fifteen minutes. The solutions were then set aside to allow the residual lead peroxide to settle, the supernatant liquid decanted, and the residue boiled with more hot water containing 20 to 25 per cent. of nitric acid. These decantations are continued as long as they show a decided colour of permanganic acid. When the manganese is below 0·60 per cent., one decantation and subsequent boiling is generally sufficient. The combined decantations are then filtered through asbestos and titrated with a standard reducing agent. The results obtained were:—

No.	A	B	
1	0·516	0·512	per cent. manganese.
2	0·516	0·513	"
3	0·513	0.518	"
4	0·518	0·518	"
5	0·513	0·518	"
6	0·513	0·513	"

These show that the presence of lead nitrate, formed by the action of nitric acid on the red lead, does not influence the accuracy of the results, neither does the difference in the time of boiling appear to exert any influence. The only difference between filtering hot and cold is that occasionally lead peroxide will run through the filter and cause too high results. The author has been unable to obtain uniformly accurate results with steel above 0·50 per cent. manganese by taking an aliquot portion of the first decantation for titration, while companion analyses treated in the usual manner have yielded results which compared favourably with gravimetric methods.—G. H. M.

Application of Nitroso-β-naphthol in Quantitative Analysis. G. v. Knorre. Ber. **20**, 283—290.

In furtherance of the methods of separating cobalt and nickel, and iron and aluminium, by means of nitroso-β-naphthol (compare Ilinski and v. Knorre, this Journal, 1885, 370, and 1886, 41), the author has investigated the action of this compound on other metals. Copper can be separated from lead, cadmium, magnesium, manganese, mercury, zinc, &c., by precipitation as copper nitroso-β-naphthol $(C_{10}H_6O.NO)_2.Cu$. The separation is effected by neutralising the solution with ammonia, which must contain the metals as sulphates or chlorides, acidifying with a few drops of hydrochloric acid, heating almost to boiling, and adding excess of nitroso-β-naphthol, dissolved in hot 50 per cent. acetic acid. After remaining for some hours in the cold the mixture is filtered, the precipitate washed, dried, ignited in a porcelain crucible, and weighed as cupric oxide. The separation of iron from chromium, manganese, nickel, zinc and other metals can be effected by the method previously described for its separation from aluminium. The methods are given in detail in the original, together with the results of check analyses. The author is continuing his investigations, and intends to study the behaviour of other nitroso compounds with metals.—D. B.

New Reaction of Thiosulphates. L. L. de Koninck. Zeits. Anal. Chem. **26**, 26.

On treating the alkaline thiosulphates, in presence of potassium or sodium hydrate, with aluminium, alkaline sulphides are produced which are easily recognised by their characteristic reactions. This decomposition would appear to take place in accordance with the equation $M_2S_2O_3 + 2NaOH + 2H = M_2SO_3 + Na_2S + 2H_2O$, the hydrogen resulting from the action of the aluminium upon the sodium hydrate. The author intends to extend his observations upon the behaviour of aluminium with the salts of the thio-acids.—W. D. B.

On the Detection of Ammonia, Nitric or Nitrous Acid, and Thiosulphuric Acid in a Mixture of their Alkaline Salts. L. L. de Koninck. Zeits. Anal. Chem. **26**, 26.

The substance in aqueous solution is distilled with soda lye in a small fractionation flask, the side tube of which dips into a U-tube containing Nessler's test solution. Any ammonia present is at once apparent, and is carefully removed by prolonged distillation. A little aluminium added to the contents of the flask and fresh Nessler solution placed in the U-tube. Nitric and nitrous acids if present are reduced, and the ammonia passes over into the Nessler solution. The contents of the flask are tested for sulphides, the presence of which indicate the occurrence of a thiosulphate in the original sample. (See preceding abstract.)—W. D. B.

Titration of Zinc and Cadmium Sulphides with Iodine. P. v. Berg. Zeits. Anal. Chem. **26**, 23—25.

The washed sulphide of zinc or cadmium is allowed to drain upon the filter, and then transferred together with the filter to a stoppered flask containing 800cc. of water deprived of air by boiling and the passage of carbonic acid gas. The whole is well shaken to break up the precipitate and bring it into the most finely divided condition possible, so that the sulphide may not be protected from the action of the iodine by separated sulphur. A moderate quantity of hydrochloric acid is added, there being no necessity to entirely dissolve the sulphide, and then an excess of iodine solution of known strength. The residual free iodine is then titrated with thiosulphate without loss of time. The whole operation, from the transference of the sulphide to the flask to the final titration, occupies about five minutes, and gives results varying between 98·8 and 100·2 per cent. The reaction proceeds according to the equation, $ZnS + 2HCl + 2I = ZnCl_2 + 2HI + S$. Owing to the ready oxidation of sulphide of manganese, this method is not applicable to the titration of that body, neither can it be employed for the titration of cobalt and nickel sulphides, as these are not attacked by the solution of iodine in hydrochloric acid.—W. D. B.

Process for the Rapid Separation of Gold, Platinum, Antimony, Arsenic, and Tin. P. J. Dirvell. Bull Soc. Chem **46**, 806.

This is a combination of Silva's method for the separation of gold and platinum from antimony, arsenic and tin by reducing the two first by means of chloral hydrate, and Carnot's method. The sulphides of the five metals precipitated by HCl from their solution are dissolved in aqua regia. A small quantity of a saturated solution of neutral sodium oxalate is added, together with a solution of oxalic acid (in quantity according to the amount of antimony present), and lastly, a marked excess of alcoholic soda. No account is taken of any sodium oxalate which may separate. The solution is heated to nearly 100°C., and an excess of chloral hydrate solution added drop by drop; heating is continued for a few moments more, and the hot solution filtered off from the precipitated gold and platinum. The filtrate is diluted, freed from chloral by boiling, acidified with hydrochloric acid, treated with an excess of sulphurous acid, and the metals separated according to Carnot's method. (*Chem. Zeit. Rep.* **10**, 198.) The whole process is rapid, and yields very accurate results.—W. D. B.

Quantitative Estimation of Boric Acid. T. Rosenbladt. Zeits. Anal. Chem. **26**, 18—23.

Advantage is taken of the ready formation of methyl borate by distilling methyl alcohol with sulphuric acid and a borate, and of the volatility of the methyl borate, in the author's method for the separation of boric acid from bases and silicic acid, and estimation the same. The following are the details of the process:—A quite dry Erlenmeyer flask, with wide mouth and of about 100cc. capacity, is provided with a doubly perforated cork through which passes a funnel with stop-cock and the end of a condenser tube. The other end of the condenser tube is carried into a similar Erlenmeyer flask through a doubly perforated cork, and a tube bent in two right angles leads from this second Erlenmeyer flask to the bottom of a little flask containing a solution of ammonium carbonate. The upper part of that limb of the tube which dips into the carbonate of ammonia is expanded into a bulb. The whole apparatus must be air-tight. The substance under examination in a fine state of division is weighed off into the first flask, moistened with methyl alcohol, the cork inserted, and concentrated sulphuric acid added from the funnel. The contents of the flask are carefully cooled during the addition of the acid, and then 10cc. of methyl alcohol are added gradually by the same funnel. The methyl alcohol and methyl borate are distilled off on a water bath, methyl alcohol being added from time to time in quantities of about 5cc. until 40—50cc. have passed through the apparatus for each 0·3grm. of boric acid. Distillation being ended, the contents of the small flask are added to the distillate, the bulb rinsed out, and 10cc. of a 10 per cent. solution of ammonium carbonate added to the united distillate and washings. During the distillation sufficient magnesia to absorb three times as much boric acid as is present is brought into a platinum basin of 40—60cc. capacity, strongly ignited, and the whole weighed as rapidly as possible. The magnesia is then moistened with solution of carbonate of ammonia, the distillate transferred to the magnesia, evaporated carefully, and the residue ignited and weighed. The increase represents the boric acid. Compounds insoluble in acids—such as silicates—are fused with sodium and potassium carbonate previous to distillation, care being taken in every instance that the substance is in a very fine state of subdivision. Results of test analyses with boric acid and several of its salts are given, and the amounts of boric acid found vary from 99·77 to 99·99 of the quantity taken or calculated. The author lays stress upon the importance of employing methyl alcohol which neither turns black nor evolves sulphurous acid when mixed with sulphuric acid and warmed on the water bath.—W. D. B.

A Method for the Separation and Estimation of Boric Acid. F. A. Gooch. Amer. Chem. J. **9**, 23—33; also Chem. News, 1887, 7—10.

In this method the author takes advantage of the volatility of free boric acid with alcohol in order to secure its removal from fixed substances, and estimates it in the distillate. Methyl alcohol answered best for this purpose. The presence of water retards the action of methyl alcohol very considerably. The author made a series of experiments, using calcium oxide in place of magnesium oxide, and found that when the solution of boric acid in methyl alcohol is allowed to stand with calcium oxide for about fifteen minutes before distilling, there is no volatilisation of boric acid. It appears, therefore, that free boric acid being easily volatilised by means of methyl alcohol, and fixed completely by calcium hydrate, the separation of the acid from almost anything with which it ordinarily occurs, and its subsequent estimation depend only upon the practicability of distilling it from its compounds in such company that it may be retained by lime, and its amount determined by the increase in the weight of the latter. Nitric and acetic acids are suitable agents, therefore, for the liberation of boric acid previous to distillation.

The author employs, for the distillation, the apparatus which is shown in the accompanying figure. It consists of a retort, condenser, and bath for heating. The latter is a paraffin bath, which has been found most convenient. The condenser is preferably set vertically. The retort is made of a pipette by bending the tube at one end to a right angle, and at the other to a goose-neck, as shown. To the former end is fitted, by a rubber stopper or piece of tubing, a glass funnel tube provided with a stop-cock; the end of the goose-neck passes tightly through a rubber stopper in the upper end of the condensing tube. The distillate is received in a small Erlenmeyer flask, which is attached to the condenser by means of a thistle-tube and a rubber stopper grooved to permit the free passage of air. A 200cc. pipette makes the most convenient sized retort. In the experiments given below, 1 to 4 were performed with nitric acid, and 5 to 8 with acetic acid to liberate the boric acid. The results obtained were:—

	B_2O_3 taken. Grm.	CaO taken. Grm.	B_2O_3 + CaO found Grm.	B_2O_3 found. Grm.	Error. Grm.
1	0·1738	0·9647	1·1392	0·1745	0·0007 +
2	0·1806	0·9639	1·1456	0·1817	0·0011 +
3	0·1776	0·9665	1·1450	0·1785	0·0006 +
4	0·1821	0·9739	1·1587	0·1848	0·0027 +
5	0·1806	1·4559	1·6371	0·1812	0·0006 +
6	0·1812	0·9720	1·1543	0·1823	0·0011 +
7	0·1788	0·9986	1·1781	0·1795	0·0007 +
8	0·1813	0·9527	1·1358	0·1831	0·0018 +

In the presence of chlorides, nitric acid cannot be employed to liberate the boric acid, and the author recommends the removal of the chlorine by means of silver nitrate, care being taken to add slight excess of nitric acid after the separation of the silver salt. Chlorides do not appear to interfere with the liberation with acetic acid; but it was found that the presence of any considerable amount of potassium acetate is disadvantageous.

This method can be applied to almost any class of substances containing boric acid.

The distillation apparatus is also capable of extensive application, and may be advantageously used for the determination of free and albuminoid ammonia in water.

—G. H. M.

On the Use of "Solid Bromine" for Decomposing Minerals, etc. A. Brand. Zeits. Anal. Chem. **26**, 222—230.

THIS "solid bromine" consists of thin rods of kieselguhr, mixed with somewhat less than 1 per cent. of lime or alkali, which are soaked in liquid bromine: the thin rods (7mm. in diameter) contain about 1grm. of bromine per cm. length, and the thick rods (15mm. diameter) about 3grms. per cm. length. On heating they give off bromine, and they can also be used for introducing any required quantity of bromine into a solution, since the kieselguhr is not acted upon.

The author has analysed fahl-ore, as well as ores of lead and nickel (containing Fe, Ag, Cu, Pb, Ni, Co, S, Sb, and As), by heating in a current of bromine, and he finds that the volatile bromides contain all the sulphur, antimony, and arsenic (as well as mercury in the case of fahl-ore); while the silver, copper, lead, nickel, and cobalt remain as non-volatile bromides. Iron was found in both, but mainly in the residue. This decomposition, by means of bromine, into volatile and non-volatile bromides is carried out in much the same way as the analysis of fahl-ores in a current of chlorine: the separation proceeds quite smoothly, and the method is cheaper and more convenient than the chlorine process. The decomposition is carried on in a tube, the front part being bent downwards and connected with two U-tubes which act as receivers. The finely-divided mineral is placed in a boat and pushed into the front part of the tube. A number of bromine-sticks are introduced behind the boat, and then the tube is closed air-tight: this is best done by pushing in a stiff paste of plaster-of-Paris, so as to form a plug 2cm. long, and closing the tube with a well-fitting cork. The two receivers are filled with HCl containing a little chlorine or bromine-water: if all the bromine-vapours are not absorbed, the operation must be carried out under a hood, or else the vapours may be led into a vessel containing shavings soaked in alcohol. The tube is now gradually heated from the plug end forwards towards the boat, so that the bromine-vapours expel the air before the decomposition commences. The reaction proceeds vigorously as soon as the boat is heated; the volatile bromides are then driven forward into the receiver, and the tube is cut off between the boat and the bromine-sticks. The decomposition of 1grm. of substance takes about half-an-hour, and before proceeding with the analysis the solution containing the volatile bromides should be poured into a porcelain dish and heated on a water-bath in a fume-closet, so as to drive off the bromine.—D. E. J.

Analyses of Chrome Iron Ore. W. Venator and E. Etienne. Chem. Zeit. **11**, 53.

THE authors give the following complete analyses of two samples of chrome iron ore from the Urals:—

	I.		II	
Chromium oxide......	51·62	51·39	55·75	55·92
Ferrous oxide	17·91	18·13	21·56	21·42

Magnesia	13·15	13·29	13·85	13·67
Lime	0·73	0·75	0·60	0·65
Silicic acid	1·71	1·71	5·37	5·37

—W. D. B.

Successive Separation of Copper, Cadmium, Zinc and Nickel or Cobalt (Iron or Manganese). Carnot. Bull. Soc. Chim. **46**, 812.

Copper and Cadmium.—The solution containing these metals is acidified with 10—15cc. of hydrochloric acid, diluted to 200—300cc., heated to boiling, and a solution of sodium or ammonium hyposulphite (thiosulphate) added in small portions until the precipitation of cupric sulphide is complete, and the supernatant liquid remains milky from presence of free sulphur. The precipitate is ignited with sulphur in a current of hydrogen, and weighed as Cu_2S. The cadmium is precipitated from the solution by H_2S or ammonium sulphide.

Cadmium and Zinc.—The solution should contain no other free acid than oxalic. By boiling with thiosulphate, an orange-yellow cadmium sulphide is precipitated, and is easily washed, but no zinc. Care must be taken that no zinc oxalate be thrown down. The sulphuric or hydrochloric acid present is neutralised with ammonia, an excess of ammonium chloride added, then about 2grms. of oxalic acid in solution, and the whole heated to boiling. If much zinc be present, or the solution not sufficiently diluted, a separation of crystalline zinc oxalate takes place, and by filtering this off, and washing with warm ammonium chloride solution, a portion of the zinc is separated, which can be weighed as oxide or sulphide. But this precipitation of zinc oxalate may be entirely avoided by the use of a sufficient quantity of potassium oxalate, which forms with the zinc oxalate an easily-soluble double salt. The solution of zinc and cadmium, prepared as above, to avoid premature precipitation of zinc, is diluted to 200—250cc., heated to 100° C., treated in separate portions with sufficient thiosulphate, and the boiling continued. The further addition of thiosulphate, or of oxalic acid, will cause no orange precipitate, when the reaction is complete. The precipitated cadmium sulphide is washed, dissolved in nitric acid, converted into sulphate by the addition of a few drops of H_2SO_4, and weighed as sulphate after ignition at a dull-red heat. The zinc is precipitated as sulphide by H_2S, and may be weighed either as oxide or sulphide.

Zinc and Nickel (or Cobalt).—Nickel and cobalt are not precipitated in the foregoing processes, and are present in the sulphuretted hydrogen solution. Sodium or ammonium acetate is added, and the solution again saturated with H_2S. The precipitate is converted into protosulphide by ignition in a current of hydrogen. In absence of cadmium, the copper is precipitated by hyposulphite (thiosulphate) from the solution containing free sulphuric or hydrochloric acid, ammonia added to approximate neutrality, and the majority of the zinc precipitated by H_2S. Ammonium oxalate is next added, and the zinc completely precipitated with a large excess of H_2S. In the filtrate, the nickel or cobalt is precipitated by H_2S after the addition of sufficient ammonium acetate.

In the Presence of Iron and Manganese.—The employment of potassium oxalate in place of ammonium oxalate is essential to prevent their precipitation by H_2S or thiosulphate in the acid solution. This is due to the formation of easily-soluble double oxalates of potassium with iron and manganese.

Zinc and Iron.—The hydrochloric acid solution is nearly neutralised with ammonia and saturated with a rapid current of H_2S, whereby the zinc is partially precipitated and the ferric salt reduced. Potassium oxalate is then added, and the precipitation of the zinc completed by means of H_2S. The iron is subsequently thrown down by ammonium sulphide. This new method for the separation of zinc and iron is in many cases to be preferred before all others.

Zinc and Manganese.—The process is the same as in the case of zinc and iron.

Zinc, Nickel (or Cobalt), Manganese.—The three sulphides are precipitated successively and respectively in the oxalic acid, acetic acid, and neutral or ammoniacal solution.

Nickel, Iron, and Manganese.—The solution in which the iron must exist as a ferric salt, is saturated with ammonia and ammonium carbonate until it has assumed a brown colour, a neutral acetate added, and an excess of H_2S passed in. Iron, nickel, and cobalt are completely precipitated, and the manganese which remains in solution is thrown down by means of ammonium sulphide.

The above-described new methods of separation are rapid, and give accurate results.—W. D. B.

*Colour Reactions for **Arsenic**, Vanadic, Molybdic, and Arsenious Acids, also for the Oxides of Antimony and Arsenic.* L. Levy. Compt. Rend. 1886, **11**, 1195.

In continuation of his researches as to the behaviour of titanic, niobic, tantalic and stannic acids, the author has investigated the colour reactions yielded by the above-named acids and oxides with the following bodies:—Morphine, codeine, phenol, thymol, α-naphthol, β-naphthol, quinol, pyrogallol, salicylic acid, *m*-oxybenzoic acid and gallic acid. These reactions in many cases suffice to indicate the presence of one of the above acids or oxides in admixture with the others.—W. D. B.

A Basic Aluminium Sulphate. K. J. Bayer. Chem. Zeit. **11**, 38.

In the manufacture of sulphate of alumina, the author has observed the formation of a basic sulphate possessing characteristic properties, in which it differs from similar compounds hitherto prepared. By dissolving aluminium hydrate, prepared by precipitation with carbonic acid, in sulphuric acid, and boiling the solution obtained with an excess of hydrate, it is found impossible to bring this excess into solution by a further addition of sulphuric acid, even though the latter be concentrated. The solution also remains acid in spite of the aluminium hydrate apparently present. The hydrate has taken up sulphuric acid without, however, being converted into a soluble compound. On isolating this insoluble residue, it is found to be insoluble in acid, and only a portion is dissolved out by prolonged boiling with sulphuric acid of 1·3—1·4 sp.gr. Hydrochloric acid appears to have no action. Two residues obtained at different times were washed and subjected to analysis, solution for this purpose being effected by means of digestion in caustic soda. The results of analysis, making allowance for the small percentage of SiO_2 present, lead to the formula $3Al_2O_3.2SO_3+9H_2O$, as appears from the following figures:—

	Theoretical.		By Analysis. I.	By Analysis. II.
Al_2O_3	48·74	....	47·76	48·72
SO_3	25·33	....	24·44	25·80
H_2O	25·73	....	27·78	25·47

In (I.) the percentage of water is too high, having been estimated by difference; moreover, the sample contained some soda, which was not estimated. The direct estimation of water by heating the sample at 200—250° C. gave 16·83 per cent., corresponding to 6mols. On further heating the sample to faint redness, further 9·20 per cent. of water were given off, and it was only when the sample was heated to bright redness that any sulphurous acid could be observed. This basic sulphate does not lose water at 100° C., nor over sulphuric acid. On heating the sulphate which has been ignited at a faint red heat, with water, a basic aluminium sulphate passes into solution, from which, on heating, a voluminous precipitate separates. This would appear to correspond to aluminite, which contains equal molecules of alumina and sulphuric acid. Attempts were made to prepare the basic sulphate by boiling an excess of aluminium hydrate soluble in acetic acid, with a concentrated solution of aluminium sulphate,—but without success.—W. D. B.

Testing Aluminium Sulphate for Free Sulphuric Acid and Aluminium Hydrate. K. J. Bayer. Chem. Zeit. **11**, 53.

The presence of free acid is most certainly and conveniently detected by the use of Tropaeolin OO, and its amount estimated by titration with normal soda, using the tropaeolin as indicator. The solution for this purpose should not contain more than 10 per cent. of aluminium sulphate. If the sample contains aluminium hydrate in solution as basic salt, this may be estimated by titration with normal sulphuric acid, tropaeolin being the indicator. The insoluble portion left on dissolving aluminium sulphate in twice its weight of water, which appears as a white turbidity, and may be present even when the solution is distinctly acid, may consist either of hydrated silicic acid or of the insoluble basic sulphate $3Al_2O_3.2SO_3+9H_2O$ already described by the author (see preceding abstract).—W. D. B.

On the Estimation of Phosphorus in Steel and Iron. P. Vorwerk. Chem. Zeit. **11**, 98—99.

The Author, having tested for three months Meineke's[*] and Wood's modifications of the Molybdenum method for the determination of phosphorus, finds that for accuracy and rapidity they are alike suitable for iron-works laboratories. The combined method he specially recommends is as follows:—Enough of the sample (0·3 to 8grms.) to give about 1grm. of the ignited phospho-molybdic precipitate, should be dissolved in nitric acid of 1·2 sp. gr., 60cc. of 1·4 sp. gr. nitric acid, and 5cc. of chromic acid solution (2grms. CrO_3) are added, and the mixture boiled for 15 to 20 minutes. The organic bodies having thus been oxidised, the solution is cooled to 50—55° C. by the addition of 50—60cc. of water. The addition now of 100cc. of 0·96 sp. gr. ammonia will raise the temperature to 75°—80°, so that the precipitation of the phosphorus with 75cc. of the usual molybdate solution may at once be proceeded with, the liquid meanwhile being well stirred. After two hours, the clear liquor may be siphoned off, and the precipitate filtered, washed as usual with acid ammonium nitrate, introduced moist into a weighed porcelain crucible, dried carefully, the filter paper incinerated, and the yellow precipitate heated to 400° C. preferably over a Berzelius lamp for 10 to 15 minutes. The blue-grey residue consists of (empirically) $P_2O_5.4(Mo_6O_{17})$, and contains 1·754 per cent. of phosphorus. If more than 3 per cent. of combined carbon be present, as in some spiegels, the chromic acid treatment will not suffice for the removal of organic impurities; but the solution is evaporated, and the residue, after careful ignition, dissolved in hydrochloric acid and filtered from silica. The filtrate is freed from excess of hydrochloric acid by evaporation, rendered slightly alkaline by ammonia, the precipitate redissolved in nitric acid, and the whole heated to 75—80° C. with 30cc. of concentrated ammonium nitrate solution (750grms. *per* litre) and precipitated as usual. Silica dissolved in the nitric-acid may generally be neglected with safety. Should, however, this body or graphite separate from the solution, the latter after oxidation of the organic substances should be made up to a given volume and filtered through a dry filter into a dry beaker, from which any convenient fraction of the solution may be taken. By keeping the weight of the ignited precipitate lower than 1grm., the ignition may be conducted in a porcelain crucible instead of in a platinum dish. A skilled analyst may thus conveniently make 20 determinations in a day of eight hours. Finally, the author criticises Huss's modification of Sonnenschein's method; Huss, under the impression that phosphorus is not completely precipitated from a nitric acid solution of steel, converts the ferric nitrate into chloride by an exact addition of ammonium chloride. This incomplete precipitation is due to organic matter and not to ferric nitrate, and is therefore equally incomplete after the addition of the chloride.—W. G. M.

Detection of Albumen in Urine. L. Blum. Chem. Zeit. Rep. **11**, 24.

The reaction with metaphosphoric acid is made use of. Owing to the fact that this acid does not keep when in solution, the following reagent is employed as a substitute:—0·03 to 0·05grm. manganic chloride is dissolved in a small amount of water, acidified with a few cc. of dilute hydrochloric acid and treated with 100cc. of a 10 per cent. solution of sodium metaphosphate. Lead dioxide is then added in small quantities at a time with constant agitation, after which the mixture is allowed to settle and filtered. The resulting pink solution of manganic metaphosphate is then used as indicator for the presence

---

[*] This Journal, 1886, 509.

of metaphosphoric acid. This solution keeps well, and is not acted on by other ingredients of urine.—D. B.

Assay of Quinine Sulphate. O. Schlickum. Pharm. Zeit. **32**, 23.

[*]To determine the presence of alkaloids other than quinine in commercial quinine sulphate, the author makes use of an observation by De Vrij, who found that quinine chromate is almost insoluble in water. It is shown that both quinine and cinchonine form chromates requiring 2000 parts of water for complete solution. The chromates of quinidine and cinchonidine are, however, more readily soluble. It was also found that a cold saturated solution of quinine chromate is not precipitated by caustic alkalis, owing to the fact that quinine hydrate is no more insoluble in water than the chromate. If, therefore, a solution of quinine is precipitated with potassium chromate, filtered after four hours' rest, and sodium hydroxide is added to the filtrate, no change should take place with pure quinine, the appearance of a flocculent or opaque turbidity being indicative of the presence of cinchonine, cinchonidine, or quinidine. Cinchonine dissolves in about 4000 parts of water, so that sodium hydroxide precipitates a cold saturated solution of its chromate (1 : 2000). The chromates of quinidine and cinchonidine dissolve in about 400 parts of water. The author has based on these ratios of solubility a method suitable for the detection of 0·5 per cent. of cinchonine sulphate or 1 per cent. of quinidine or cinchonidine sulphate in quinine sulphate.—D. B.

Estimation of Colchicine. A. Kremel. Pharm. Post. **20**, 38.

20GRMS. of colchicine seeds are exhausted in an extraction apparatus with alcohol of 90 per cent. The liquid is diluted with 25cc. of water, and the alcohol removed by evaporation. The residue is filtered and washed, and the filtrate agitated three or four times with 10 or 15cc. of chloroform. The mixed extracts are then evaporated, the residue is dissolved in water, again agitated with chloroform, and treated as before. The final residue is dissolved in a few cc. of water, evaporated, dried over sulphuric acid, and weighed.—D. B.

Reaction for Levulose. Ber. **20**, 181—182.

WHEN a cold aqueous solution of two parts of cane sugar and one part of resorcinol is mixed with concentrated hydrochloric acid and quickly warmed, a red colouration takes place, and on cooling a considerable dark precipitate is deposited, which is soluble in alcohol with a beautiful red colour. Levulose and raffinose also give this reaction with resorcinol, but dextrose, galactose, maltose, milk sugar, and inosite do not give any colouration. It appears that this reaction is only given by carbohydrates which contain or which yield levulose on inversion. The precipitate is analogous to those obtained by Michael (this Journal, 1884, 253), by the condensation of aldehydes with resorcinol. The author found that levulose acid gives Baeyer's aldehyde reaction with phenol. When dissolved in alcohol the condensation product gives a fine red colour, which on addition of alkali is first turned blue, then green, and finally dirty yellowish-grey. When water is added to an alcoholic solution of one part levulinic acid and one part resorcinol, to which fuming hydrochloric acid has been added, a white resinous precipitate is thrown down analogous to that described by Michael (*loc. cit.*). This turns red in the air. Quinones and pyroracemic acid give the same reaction.—G. H. M.

Detection of Minute Quantities of Aldehyde in Alcohol. W. Windisch. Ztschr. f. Spirit-Ind. **9**, 519.

ON treating aldehyde in aqueous or alcoholic solution with a freshly-prepared aqueous solution of metaphenylenediamine hydrochloride, a yellow colouration is obtained which is sufficiently sensitive to admit of the detection of one of aldehyde in 200,000 parts of the solution.—D. B.

New Process for the Determination of Tannin. M. Villon. Bull. Soc. Chim. **47**, 97.

THE determination of tannin is a matter of difficulty. On the one hand, the same process gives different results with extracts of different origin containing the same amount of tannin, and on the other, different processes applied to the same extract also give different results. Substances, also allied to tannin, but which do not form leather, such as gallic, ellagic, glauco-melonic and gallamic acids, occur in extracts along with tannin, and are estimated with it by certain methods. The author states that of the 32 methods for determining tannin, that of Hammer, that of Muntz, which is a modification of Hammer's, and that of Löwenthal are the only ones which give satisfactory results. The author precipitates the tannin with a solution of lead acetate, and states that gallic acid is not precipitated. Liebig and Strecker first remarked that tannin gave a yellow precipitate with lead acetate. Stein, in 1857, determined tannin by precipitating with a boiling solution of lead acetate in excess, filtering, drying, and igniting the precipitate, and from the weight of the lead oxide obtained, calculating the tannin. The precipitate of lead tannate varies in composition according to the temperature and concentration of the solution, but the author finds that in a liquid containing a weight of lead acetate equal to three to five times that of the tannin, the precipitate formed has a constant composition and is not dissociated by water. The addition of sodium acetate promotes the precipitation. Upon these facts he founds the following process:—The tannin solution is made of a strength of about 2grms. of tannin per 100cc. The lead solution contains 100grms. of neutral lead acetate and 20grms. of sodium acetate per litre. 100cc. of the tannin solution are mixed with 100cc. of the lead solution left for five minutes, and then filtered. The sp. gr. D of the lead solution, the sp. gr. D′ of the tannin solution and the sp. gr. d of the filtered mixture are taken, all at the same temperature. The calculation of the amount of tannin is as follows:—If the two liquids mixed without precipitation or alteration in volume, the sp. gr. of the mixture would be $\frac{D+D'}{2}$; but as the lead tannate disappears from the liquid the sp. gr. is diminished thus:—$\frac{D+D'}{2}-d$.

Let E be the difference of sp. gr. produced in 100cc. of an aqueous solution by the disappearance of the same weight of tannin as that precipitated as lead tannate; probably $\frac{D+D'}{2}-d$ will be proportional to E, whence

$$\left(\frac{D+D'}{2}-d\right)A=E.$$

This equation permits us to calculate E, if A is determined once for all, and from E to deduce p, the weight in grammes contained in 100cc. of the solution in question, by means of Hammer's table. This table may be summed up in the following formula:—$p=\frac{E}{0{\cdot}00405}$. The constant A is not the same for all the tannins; for gallotannic acid it is 50 per cent.; for quercitannic acid, 45·3; castaneotannic, 44·8; aspidospertannic, 42·5; abietannic, 40; and catechutannic acid, 52 per cent.
—B. H.

Butter Analysis. F. W. A. Wolt. Zeits. Anal. Chem. **26**, 28—33.

THE author has made a series of test analyses of mixtures of genuine butter and "oleo-oil" containing 20, 40, 50, 60, and 80 per cent. of the former, by Köttstorfer's and Reichert's methods respectively, with a view of determining the degree of accuracy of which the two methods are capable. By Köttstorfer's method the mean error was 6·5 per cent., the maximum error 16·1 per cent., the percentage of genuine butter indicated being

---

[*] See this Journal, 1887, p. 306.

too low on account of the low percentage of alkali (222·2 to 223·2mgrms. per grain) actually required by the genuine butter; whilst in calculating the results Kottstorfer's mean value, 227, was employed. By Reichert's method closer results were obtained, the maximum error being +4·5, the mean error only +2·3 per cent. The results of examination of thirty-seven samples of butter, butterine, and butterine materials are given, and these confirm the value of the indication which specific gravity affords as to the genuineness of a sample. With the exception of sesame and cocoa-nut oils the specific gravity of all the commonly-used butterine materials falls below 0·90536, whilst that of genuine butter falls between 0·911 and 0·914. The minimum specific gravity of genuine butter is usually placed at 0·912, but in seven samples examined the figures were below this, the lowest specific gravity obtained being 0·91107.—W. D. B.

Modification of Otto's Acetometer. W. Fresenius. Zeits. Anal. Chem. **26**, 59—60.

This modification consists of a glass cylinder 12mm. in diameter, 17—18cm. high, closed at the lower end and graduated into fifths or tenths of a cc. The first graduation mark is at 5cc. from the bottom, and the divisions into fifths or tenths proceed from this to the 12cc. mark. In the performance of the test the apparatus is filled to the 5cc. mark by means of a pipette to avoid soiling the upper part with the vinegar under examination, a few drops of phenolphthalein solution added, and the standard soda run in and carefully mixed until a red tint is acquired. The volume in cc. of the soda solution is then read off, and this gives without calculations the number of grms. of anhydrous acetic acid in 100cc. of vinegar, if the soda solution is of the strength recommended by Fresenius for vinegar testing—namely, the litre corresponding to 50grms. of anhydrous acetic acid.
—W. D. B.

Reactions of Duboisine, Hyoscyamine, and Atropine. Chem. Zeit. **11**, 52.

Although the researches of Ladenburg would indicate the identity of duboisine with hyoscyamine, these two alkaloids exert very different physiological actions. According to Harnack, duboisine acts with about five times the power of purest recrystallised hyoscyamine, and two or three times more powerfully than atropine. The physiological differences between the alkaloids in question being so marked, it is very desirable to have a means for their chemical discrimination, and for this advantage is taken of their behaviour with alcoholic solutions of mercuric chloride. The action of this reagent with atropine was first pointed out by Gerrard, and Schweissinger has extended observations with the following results:—By dissolving about 1mg. of atropine in 1—2 drops of water in a test glass—which to hasten solution may be immersed in hot water—and adding 2cc. of a 5 per cent. mercuric chloride solution in alcohol of 50 per cent., a reddish-brown precipitate is obtained. Pure crystallised hyoscyamine tested in the same way gives a clear solution, which after continued warming on the water bath shows a faint opalescence. Pure crystallised duboisine under the same conditions gives a white turbidity immediately, and on warming a white precipitate. The amorphous base hyoscine, isomeric with atropine and hyoscyamine gives a clear solution when tested as above, and no change takes place on prolonged warming.—W. D. B.

Analysis of Platinum. C. Reinhardt. Chem. Zeit. **11**, 52.

In the examination of metallic platinum to be used for making crucibles it is frequently found a matter of great difficulty to effect solution in aqua regia or hydrochloric acid and potassium chlorate. To obviate this difficulty the author takes advantage of the fact that platinum may be readily alloyed with several metals of common occurrence, and that the alloys are easily brought into solution by acids. Experiments were made with various metals, but it was found that zinc was in every respect the most convenient. The weighed sample of platinum is mixed in a well glazed porcelain crucible with pure metallic zinc and the mixture exposed to the heat of a muffle furnace. When cold, the contents of the crucible are treated with cold hydrochloric acid of 1·124 sp. gr., which dissolves the zinc, leaving untouched a residue of grey metallic needles. These latter are washed, and dissolved in aqua regia. Solution now takes place rapidly, and the analysis is proceeded with in the usual manner.—W. D. B.

Detection of Salicylic Acid in Food. H. Taffe. Bull. Soc. Chim. **46**, 808.

To avoid the extraction of tannin substances when the drink under examination is shaken up with ether, the author advises the employment of a mixture of ether and petroleum ether in equal volumes, as this neither contains water nor takes up water when shaken therewith. By using this mixture, foreign substances are not extracted, and it is possible to obtain the colour reaction with ferric chloride with great certainty, and without it being necessary to purify the ether and petroleum ether extract, even when the quantity of salicylic acid is very minute. According to the author, this plan is to be preferred before all others for the rapid and certain detections of salicylic acid. Since beer gives with the mixed ethers an emulsion which separates very slowly, the author advises that after the mixing, agitation, and standing, a second quantity of the ether mixture be added and carefully stirred with the upper layer or the emulsion, from which it abstracts a portion of the salicylic acid.—W. D. B.

Estimation of Fatty Acids in Soap. B. Schulze. Zeits. Anal. Chem. **26**, 27.

The weighed sample is brought into solution in an Erlenmeyer flask, decomposed with dilute sulphuric acid, and the separated fatty acids dissolved out in ether. The aqueous solution is removed as completely as possible by means of a pipette, and the ether washed three or four times with fresh water, care being taken to remove the aqueous layer as completely as possibly. After the last washing and drawing off of the water, a few drops of barium chloride solution are added, and any free sulphuric acid thus precipitated. The amount of water being so small, the ethereal solution may be at once passed through a filter, and thereafter treated in the usual manner. The fatty acids obtained in this way are completely free from sulphuric and hydrochloric acids, and do not darken at 100° C.—W. D. B.

New Books.

Lauber's Handbuch des Zeugdrucks. Herausgegeben von Dr. Ed. Lauber, unter mitwirkung von Albert Steinheil, Dr. W. Haussmann, and Moritz Kohn. I. Band. Dritte Auflage. Leipzig, 1886. Commissionsverlag von Gustav Weigel.

8vo volume in paper cover. Price 6s. Contains 122 pages of subject matter, Table of Contents and Alphabetical Index. The work is illustrated by three woodcuts, and the subjects of which it treats more particularly in this first volume, are: Chapter I. Singeing the Goods. Bleaching and Shearing. Chap. II. Preparation of the Printing-colours. Chap. III. Preparation of the Rollers. Chap. IV. Fixing the Colours with Steam, etc. Chap. V. Turkey-red Oil; Blocking the Goods. Chap. VI. Continuous Soap and Washing Machine. Chap. VII. Soap in Dyeing; Investigation and Preparation of the Soap. Chap. VIII. Water in Dyeing; Investigation and Purification of Water. Chap. IX. Chlorination of the Perpared Goods; Dry and Damp Chlorine. CHAP. X. Albumen Colours; Testing the same on the Fibre; Testing Albumen; Ultramarine, Chrome Green, etc. CHAP. XI. Reserve with Albumen Colours. CHAP. XII. Steam Colours by decomposition of Metallic Salts, etc. CHAP. XIII. Colours Developed either by Mutual Decomposition or by Volatilisation of Acids, etc.

THE PRINTING OF COTTON FABRICS, comprising Calico Printing, Printing and Dyeing. By ANTONIO SANSONE. Manchester: Abel Heywood & Son, 56 and 58, Oldham Street. London: Simpkin, Marshall & Co., Stationers' Hall Court. Hamilton, Adams & Co., 32, Paternoster Row. 1887.

THIS important work consists of an 8vo volume bound in cloth; contains Preface, 375 pages of subject matter, illustrated by 32 well-executed engravings of plant and apparatus used by Calico Printers, a selection of 12 printed and dyed Patterns, a Table of Contents and Alphabetical Index, followed by one serving as an Index to Practical Recipes. The Table of Contents contains the key to the plan of the work as a whole:—History of Calico Printing; Bleaching. RAW MATERIALS, including Mineral Colours, Natural Organic Colouring Matters, Coal-tar Colours, Mordants, etc.; Thickening or Sizing Materials, Water. PRINTING PROCESSES: Preparing Thickenings and Mordants, Printed Colours (direct), Steam, Oxidation and Reduction Colours (Printing Colours or Processes of recent introduction). DYED COLOURS, including Alizarin Colours (Madder styles), Resists, Discharges, Turkey Reds, Alizarin Reds, Indigo Prints, Manganese Bronze Colours, Benzopurpurin and allied Dyestuffs. THE PRINCIPAL STYLES IN CALICO PRINTING, MACHINERY AND APPARATUS, FINISHING PRINTED GOODS, ELECTRICITY IN PRINTING, PRINTING WOOLLEN FABRICS, COMPARATIVE TABLE OF BAUME AND TWADDELL DEGREES.

CHEMISTRY FOR BEGINNERS. Adapted for the Elementary Stage of the Science and Art Department's Examination in Inorganic Chemistry. By R. L. TAYLOR, F.I.C., F.C.S., Teacher in Chemistry and Physics in the Central Higher Grade Board School, Manchester. London: Sampson Low, Marston, Searle and Rivington, Crown Buildings, 188, Fleet Street.

SMALL 8vo volume bound in cloth. Price 1s. 6d. Containing Preface, Table of Contents, 94 pages of subject matter, Appendix giving an account of the Metric System of Weights and Measures, nine select Groups of Questions on each Chapter of the work, and an Alphabetical Index. With the text are interspersed 21 wood engravings. As regards the extent of the subjects treated of, this is confined to the non-metallic elements.

AUSFÜHRLICHES LEHRBUCH DER CHEMIE. Von H. E. ROSCOE und C. SCHORLEMMER. Vierter Band: Die Kohlenwasserstoffe und Ihre Derivate, oder Organische Chemie. Zweiter Theil, Zweite Abtheilung. Braunschweig: Druck und Verlag von Friedrich Vieweg & Sohn. 1887. London: H. Grevel & Co., 33, King Street, Covent Garden.

8VO VOLUME in paper cover, forming the second part of the fourth volume of the German version of this well-known work. It contains matter from page 337 to 672, with which are interspersed one or two wood engravings. Essentially, it contains the description of the aromatic compounds with seven atoms of carbon, and covers consequently, like the preceding part, a complete field. The first section concerns Toluene and the derivatives corresponding to those treated of under Benzene. Then follows the Benzyl group, which joins itself to the Benzoyl group, and the volume is concluded with the treatment of the Hydroxy-benzyl- and Hydroxy-benzoyl-compounds.

NEW COMMERCIAL PLANTS AND DRUGS. No. 10. By T. CHRISTY, F.L.S., M.S.C.I., etc. London: Christy & Co., 25, Lime Street, E.C. 1887.

8VO VOLUME bound in paper. Price 3s. 6d. Contains a Preface, Table of Contents, 120 pages of subject matter, with which are interspersed numerous excellent wood engravings, and an Alphabetical Index. The following subjects are treated of:—Strophanthus, its Botany, Chemistry, Pharmacy, Physiology, and Therapeutics; the Colonial and Indian Exhibition; Hints on the Cultivation of Dry-yielding Plants in Great Britain; Notes from actual Practice in the Treatment of Disease with Jambul, Salix Nigra, Kava-Kava, Siegesbeckia, Papaw, Hydrocotyle, etc.; Gogo Plant, Chlorocodon Whitei; Huamawripa; Kola Chocolate; Ditana Digitifolia, and particulars of many other new and rare drugs; Reports and Produce received and examined.

Trade Report.

(From the Board of Trade Journal.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

RUSSIA.

Classification of Articles in Customs Tariff.

(*Note.*—Poud = 36lb. avoirdupois. Gold rouble = 3s. 2d.)

Carbonic Strontium.—Section 137, part 2, duty 1 rouble, 20 copecks per poud.

SWITZERLAND.

Classification of Articles in Customs' Tariff.

(*Note.*—Quintal = 220·4lb. avoirdupois.)

Soda, unprepared, crystallised, and calcined. Category 16, duty 30 centimes per quintal.

Sulphate of barytes, purified, in paste. Category 30, duty 60 centimes per quintal.

Plates of glass for photography, ready for use, dried. Category 17, duty 30 francs per quintal.

ITALY.

Alterations in Customs' Tariff.

Mr. J. G. Kennedy, Her Majesty's Chargé d'Affaires at Rome, writing under date of the 23rd April last, says that a law approving the temporary application for a period of three months of certain amended customs duties which passed the Chamber on the 20th April came into force on the 22nd of that month. The following is a statement of some of the amended Customs duties in question:—

Tariff No.	Tariff Classification.	Amended Rates of Duly.
		Lire c.
8	Mineral and resinous oils:—	
	(a) Raw - - Per qointal.	38·00
	(b) Refined - - - „	17·00
	Mineral oils, whether raw or refined, imported in demijohns, or other similar vessels, shall pay 41 lire per 100kilos., if raw, and 51 lire, if refined, with a deduction from each quintal, gross weight, of the general tare of 15 per cent.	
	Mineral oils, whether raw or refined, imported in casks, cases, or tins, shall pay duty according to their net legal weight, *i.e.*, with deduction from the gross weight of the following special tares for each quintal of gross weight:—	
	Barrels and kegs with iron hoops, 15kilos.	
	Wooden cases containing two canisters of tin apiece 14kilos.	
	Tin canisters, 5kilos.	
	If, however, they are imported in vessels other than those referred to above, they shall pay according to gross weight.	
	Mineral oils, whether raw, or refined, if imported in cistern-trucks or reservoir ships, shall be charged by actual net weight.	
	(c) Heavy:—	
	1. If containing 20 per cent., or less, of light oil at the temperature of 310 degrees - „	6·00
	2. If containing more than 20 per cent., and not more than 30 per cent., of light distilled oil at the temperature of 310 degrees - - „	12·00
	Heavy oils, imported in their original receptacles, pay according to gross weight.	
	If imported in cistern-trucks or vessels, they pay upon the net actual weight, with an increase of 20 per cent.	

Classification of Articles in Customs' Tariff.

Mixture of fish-oil and fatty substances. Category 1, No. 7*b*, duty 6 lire per quintal.

Linseed oil containing essence of turpentine, and not used as a varnish. Category 1, No. 7*b*, duty 6 lire per quintal.

Fish-oil mixed with lubricating mineral substances. Category 1, No. 7*b*, duty 6 lire per quintal.

Acetic acid, concentrated and artificially coloured. Category 3, No. 29*h*, duty 10 lire per quintal.

Dissolved iron and iron held in solution by glucose or molasses. Category 3, No. 56, duty 130 lire per quintal.

Iron, pulverised, for medical use. Category 3, No. 56, duty 120 lire per quintal.

"Terpina." Category 3, No 55, duty 10 lire per quintal.

Artificial black containing aluminium, flint, chalk, etc., but without phosphoric acid. Category 1, No. 70*e*, duty 5 lire per quintal.

Varnish for shoes, composed of anilin colour dissolved in spirits of wine. Category 1, No. 67*a*, duty 30 lire per quintal.

Red colouring matter, containing a very large proportion of aluminium. Category 13, No. 217, duty 4 lire per quintal.

Mixture of clay, hair, and other organic substances and water, forming a mortar intended as a covering for tubes in order to prevent condensation of steam. Category 13, No. 218*a*, duty free.

Tannic acid mixed with dextrin. Category 11, No. 246, duty 3 lire per quintal.

Refrigerating apparatus. Category 16, No. 297*a*, duty 60 lire per quintal.

AUSTRIA-HUNGARY.

Customs Decision.

Camphor oil, made from raw camphor, is in future to be included in Category 107*a* of the tariff. Duty, 6 florins per 100kilos.

UNITED STATES.

Customs Decision.

An importation found upon chemical analysis to consist of magnesium-chloride, a chemical salt, is dutiable under the provision for "all chemical compounds and salts," under section 92, and is not entitled to free entry as a substance "expressly used for manure," under paragraph 505 of the free list.

MISCELLANEOUS TRADE NOTICES.

BEER ADULTERATION IN THE ARGENTINE REPUBLIC.

Mr. R. Bridgett, Her Majesty's Consul-General at Buenos Ayres, in a report dated March 4 last, states that, by a recent ordnance of the Municipality of Buenos Ayres, the sale of beer containing salicylic acid is forbidden after March 31, 1888, under a penalty of twenty dollars for each case or cask, and forfeiture of the same. Until then the seller must show on the ticket or wrapper, or must otherwise certify the amount of salicylic acid contained in the liquid up to a maximum of fifty centigrammes per litre, or if it does not contain any acid it must be similarly made known.

TRADE OF JAPAN DURING 1886.

A despatch, dated March 16 last, has been received from Sir F. R. Plunkett, Her Majesty's Minister at Tokio, enclosing copies of the annual report of the Yokohama Chamber of Commerce for the year 1886. From this report it appears that the import and export trade of the whole of Japan for the year 1886 show an increase of £591,000 and £2,423,000 respectively over the preceding year. The total combined value of imports and exports for 1886 is given at £16,221,585, as compared with £13,201,083 in 1885, the total increase, therefore, amounting to above three millions sterling.

RUSSIAN TRADE IN 1886.

The *Journal de St. Pètèrsbourg* for April 2 last, contains an article on the foreign trade of Russia for 1886, founded upon the report of the Russian *Administration des Douanes*. The receipts, it is stated, show an increase of about 10 per cent. upon those for 1885, but this is exclusively the result of the increased duties charged upon foreign goods imported into Russia. The revenue from exports has diminished, and the commercial crisis appears to be as severe as ever. The bad harvest of 1885 exercised an unfavourable result on the export of cereals in 1886, and the general diminution of exports in this class is no less than 21 per cent., the total amount exported being less than in any year since 1881. The general stagnation of trade is, according to the *Journal*, as marked in the ports of the Black Sea and the Sea of Azov as in the Baltic.

COMMERCIAL MUSEUMS AT FRANKFORT AND AMSTERDAM.

The Belgian *Bulletin du Musèe Commercial* for April 9 last states that the Commercial Museum established by the Chamber of Commerce at Frankfort-on-the-Main is now opened to the public. It also announces that the Association for Exportation from the Kingdom of Saxony is about to open a Commercial Museum in Amsterdam.

CAMPHOR MONOPOLY IN FORMOSA.

The following information, respecting the camphor monopoly in Formosa, is extracted from a recent report by the United States Consul at Amoy:—

"The reports of the customs authorities in Formosa indicate a constant diminution in the production of crude camphor during the past two years, and the early extinction of that industry from among the industrial pursuits of that island.

"Since the termination of the Franco-Chinese war, Formosa has been made a separate province and placed under the jurisdiction of a Governor-General, who has instituted many new taxes, formerly quite unknown in Formosa; and among these, on the lingering remains of the camphor industry, he has erected a Government monopoly of that business, which, from all the information I can gather, seems likely to hasten its speedy extinction. This camphor monopoly, so created, is comparatively of little moment, except as it seems to be a revival of the old *co-hong* system, and a restriction upon the foreign trade of Formosa, so far as the article of camphor is concerned.

"Some very intelligent foreigners regard this as but the first step, a feeling of the way, by the native authorities of Formosa, to similar Government monopolies in other and more important articles of industry and trade that might cause irreparable injury to foreign commercial interests connected with the trade of Formosa, such, for instance, as the tea and sugar trade."

TRADE STATISTICS FOR APRIL.

The Board of Trade Returns for April show the following figures:—

Exports.

	April, 1886.		April, 1887.
British and Irish Produce	£16,117,801	....	£16,441,662
Foreign and Colonial Produce (partly estimated)	5,168,697	....	5,716,339

Imports.

	April, 1886.		April, 1887.
Total value....................	£26,066,751	....	£31,149,925

Below are the details affecting drugs and chemicals:—

Exports.

		Apr. 1885.	Apr. 1886.	Apr. 1887.
British and Irish produce:—				
Alkali	cwt.	611,179	518,108	526,983

TRADE BETWEEN SPAIN AND THE UNITED KINGDOM.

Imports into the United Kingdom from Spain.

Principal Articles.		March 1886.	March 1887.
Chemical Products unenumerated	Value	£7,274	£6,590
Copper Ore and Regulus	Tons	2,302	3,615
	Value	£60,921	£70,628
Manganese Ore	Tons		1,600
	Value		£2,400
Pyrites of Iron or Copper	Tons	51,567	48,351
	Value	£103,543	£92,545
Quicksilver	lb.	149,925	300,000
	Value	£35,194	£29,500
Total Value for March		£815,407	£906,072
,, ,, April		£781,457	£799,058

Exports of British and Irish Produce from the United Kingdom into Spain.

Principal Articles.		March 1886.	March 1887
Alkali	Cwt.	33,482	30,865
	Value	£12,257	£10,492
Caoutchouc Man'f'ctures	Value	£1,951	£1,250
Cement	Tons	245	158
	Value	£505	£354
Chemical Products, including Dye-stuffs	Value	£2,931	£3,660
Products of Coal, including Naphtha, etc.	Value	£1,979	£1,623
Manure	Value	£5,913	£10,464
Soap	Cwt.	664	281
	Value	£555	£252
Total Value for March		£286,698	£327,115
,, ,, April		£273,145	£246,897

CONSULAR REPORTS.

(From the Chemist and Druggist.)

Argentine Republic.

Pharmaceutical Imports.—The imports of articles of pharmaceutical interest into the Argentine Republic during the year 1885 are officially stated to have amounted to 2,497,349 dols., which is probably rather below the real value, considering the heavy import duties prevailing. This total is made up of the following items:—

Alcohol (duty 50 per cent.) 245,390 litres, value 162,081dols., principally from Germany; prepared colours, value 195,579dols., principally from England; sheep medicines (duty free), value 234,736dols., from England, Germany, and Italy; prepared medicines (duty 25 per cent.), value 576,443dols., from France and England; perfumery (duty 50 per cent.), value 202.353dols., from France; pharmaceutical substances and products (duty 25 per cent.), value 98.679dols., from Germany and England; chemical substances and products (duty 25 per cent.), value 180,554dols., from Germany and England; soda ash (duty 25 per cent.), 1803 tons, value 104,101dols., nearly all from England.

The United Kingdom furnished about one-third of the total value of these imports, the precise figures being—

	Dollars.
Linseed oil	60,860
Prepared colours	163,557
Sheep medicines	62,246
Prepared medicines	127,651
Soda ash	94,231
Other chemical products	410.571
Total of chemical and pharmaceutical imports	819,116

Chile.

Foreign Trade.—The foreign Trade of Chile is not, apparently, in a flourishing condition. The customs duties in 1885 yielded about 10 per cent. less than in 1881, while both imports and exports have been falling steadily since 1883.

Iodine.—There is a heavy export duty on this article, from which, in 1881, a revenue of £54,755 was derived, and of £21,436 in 1885.

Japan.

Export Statistics.—Among the articles exported from Hiogo and Osaka the following are named:—

—	—	1886.	1885.
Antimony	Piculs	31,009	36,130
Aniseed	,,	983	1,360
Camphor	,,	36,632	21,199
,, oil	,,	5,808	3,380
Cuttlefish, dried	,,	18,922	12,271
Fish oil	,,	702	1,317
Gallnuts	,,	1,847	2,064
Ginseng	,,	266	545
Isinglass	,,	7.237	7,595
Medicine	Dollars	39,300	50,000
Rapeseed	Piculs	1,600	2.549
Seaweed	,,	20,296	26.952
Soap	Cases	85,734	142.453
Sulphuric acid	,,	6,270	6.193
Tallow	Piculs	838	2,821
Wax, bees'	,,	35	51
,, fish	,,	120	141
,, vegetable	,,	12,899	13,707

COSTA RICA.

In San José, the capital of this Republic, a city of 30,000 inhabitants, there is not, our consul states, a single British house of business, although all other principal civilised nations are represented. The resources of the country are being steadily developed, and the imports for 1886, although the customs duties at the beginning of that year were increased by about 10 per cent., show no decline upon preceding years.

Exhibition of Produce.—A very successful exhibition of Costa Rican products was held at San Jose last year, as a preliminary to the Paris International Exhibition of 1889, where the Republic will, it is thought, make a considerable show. Among the articles exhibited were a large selection of medicinal plants and dyeing materials, natural mineral waters, anise, linseed, sarsaparilla, vanilla, quince seed, castor oil, essential oils, etc.

ECUADOR.

Business prospering.—In reviewing the trade and commerce of the Republic for 1886, our consul observes that the country has been in a more settled state than was the case during the preceding years. In 1886 there have only, our representative dryly remarks, been "several alarms of political disturbances, and continuous revolts of an insignificant nature, on the part of some disaffected citizens known as the Montoneros." This, for Ecuador, is no doubt the very acme of tranquillity, and under these propitious conditions the development of the country's resources is progressing with great rapidity. The staple products of the Republic are cocoa, indiarubber, coffee, and hides, show a large increase in production, and the purchasing power of the country has correspondingly increased. Public works are being extended in all directions.

Cinchona.—Of Peruvian bark, 2987 quintals (value £8961) were exported in 1885, and only 613 quintals (value £2452) in 1886. This is the only article showing a decrease during the past year, and it may be noted that the collection of cinchona has now been almost abandoned, owing to the difficulty of its transport through the forests of the interior, and the fact that its value has so declined as to render the product insufficient to cover expenses and freight. The abolition of export dues and reduction in freight, have not been found sufficient to overcome this drawback.

RUSSIA.

Russian Petroleum.—Our Odessa correspondent writes that the demand for Russian petroleum, both in Russia and foreign countries, is so rapidly increasing that the Transcaucasian Railway will shortly be unable to maintain the necessary traffic for its transport. It is, therefore, essential that pipes be put down from Baku to Poti and Batoum. Negotiations in this direction are now being carried on at the capital, and it is said that the laying down of the pipes will shortly be commenced, and that the railway company is to obtain the concession. During the past year large reservoirs were constructed in London, Antwerp, Trieste, and Tunis for the reception of Russian petroleum direct from tank steamers, and these are already in use. It is rumoured that an excise duty on petroleum in its present state is to be imposed, but the general opinion is that this step would be detrimental to all, excepting the large exporters, and that until the pipe referred to above is laid down and the trade properly developed and extended, the imposition of the excise should be deferred, for then the tax would influence the price of petroleum only to a small degree, and the fear of seeing the industry monopolised by a few of the larger and more powerful exporters would not be realised.

Monthly Patent List.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

5665 A. Thomson, Sheffield. An improved steam, water, or gas cock or tap. April 19

5676 J. Platt, Sheffield. Apparatus for obtaining more perfect combustion of fuel in the furnaces of steam generators. April 19

5705 E. Edwards—From E. C. Sonnett and A. A. Leredde, France. Apparatus for generation of steam and formation of a vacuum, to be used for preserving food, forcing water, and other purposes. April 19

5730 J. Metcalfe and E. Davies, London. Injectors or apparatus for feeding steam boilers or generators, and for other purposes. April 20

5731 E. Davies and J. Metcalfe, London. Apparatus for feeding steam boilers or generators, and for raising and forcing liquids. April 20

5793 J. King, Liverpool. Apparatus for use in the roasting, drying, carbonising, or torrefying of farina, dextrin, manures, feeding stuffs and other materials; for the heating, concentrating, evaporating and distilling of liquid and other bodies; for heating disinfectors for hospitals, and water for baths and other purposes. Complete specification. April 21

5890 T. Firth, London. An improved high pressure tap. April 22

5927 J. K. Broadbent and A. Budenberg, Manchester. Improvements in and relating to apparatus for preventing smoke and regulating the supply of air to furnaces. April 23

5982 L. A. Enzinger, London. Improvements in filter presses. April 25

5990 H. Cotton and R. Moon, Liverpool. Improvements in and applicable to furnaces to promote combustion.

5993 J. Ruscoe, Hyde. Self-sealing retort lids, cross bar, and fastening. April 25

6007 J. Weir and G. Weir, Glasgow. Apparatus for condensing steam, or for heating or evaporating by means of steam. April 25

6054 E. Schorah, Halifax. An improved machine for carbonising fabrics and fibres. April 26

6061 J. Balbirnie, Sheffield. Apparatus for burning substitutes for coal, coke, or other combustibles; the result, a cheap self-feeding fire or furnace. April 26

6218 J. W. Holden, London. Improvements in forced draught and smoke-consuming apparatus for steam boiler and other furnaces. April 28

6261 J. Buchanan, jun. See Class XV.

6372 W. J. Cooke, Manchester. Improvements in injectors for raising and forcing water or other liquids. May 2

6424 J. C. Aitken, Glasgow. Steam condensers. May 3

6441 J. D. Noble, London. Means for opening and closing valves, cocks, taps and the like, and controlling the flow of gas, steam, water, and the like. May 3

6612 C. Burnett, London. Improved apparatus for raising water and other liquids. May 5

6686 J. Y. Johnson—From P. Guillaumin, France. Improvements in weigh bridges, weighing machines, dynamometers, and similar instruments or apparatus for measuring weight or force. May 6

6705 R. Fergusson, Liverpool. Economical production of steam. May 7

6727 A. Beldam, Liverpool. Improvements in "non-return valves" employed in apparatus for raising and forcing fluids in water service systems, and for analogous purposes. May 7

6776 E. Korting, London. Improvements in injectors. May 9

6781 H. Appleby and J. G. Robinson, London. Blast pipes, and means for regulating the draught created thereby. May 9

6807 J. W. Hyatt, London. Water purifier and filter for steam boilers. Complete Specification. May 10

6838 R. Chambers, Handsworth. A steam boiler composition injecter. May 10

6860 P. Sedlak, London. Apparatus for filtering water and other liquids. May 10

6907 W. P. Thompson—From A. E. Lebret, France. Improvements in barometers, hygrometers, and the like. May 11

6908 A. Horne, Liverpool. Automatic apparatus for stopping injecting or pumping apparatus, when the level of the liquid pumped in the hot well or reservoir falls to a given point, and starting the apparatus when the liquid rises to a given height. May 11

6985 A. Pottier, London. Apparatus for separating solid impurities from the water of steam boilers. May 12

7034 O. W. Bennett and S. O. Hemenway, London. Carburetting apparatus. Complete specification. May 13

7078 P. Williams and W. Powles, London. Electrical water level apparatus for indicating by direct reading the capacities and rise and fall of gasholders, water in reservoirs, etc., and for other purposes. May 14

7111 H. H. Lake—From Zonca and Bella, Italy. Grinding mills. Complete specification. May 16

COMPLETE SPECIFICATIONS ACCEPTED.*

1886.

7755 J. Holden. Injector for feeding furnaces with liquid fuel. May 11

8481 H. H. Salomons. Retort covers, lids or doors. April 30

8523 A. Myall—From J. McIntyre. Surface condensers. April 30

8583 A. J. Boult—From S. Bond. Apparatus for consuming smoke and saving fuel. May 4

8787 G. Yellott. Centrifugal pumps. May 4

8905 S. Vickess. Apparatus for separating impurities or objectionable matter from solids. May 14

9038 A. Myall—From J. McIntyre. Surface condensers. May 11

9181 J. G. Galley. Apparatus for preventing the formation of incrustation on the surface of boiler flues, and for removing such incrustation if formed. May 18

9198 A. Harrison. Apparatus for charging and drawing heating, smelting and other furnaces. May 18

10370 S. Vickess. Apparatus for filtering liquids. May 11

12867 J. W. Lovibond. Apparatus for standardising intensity of colour in transparent bodies. April 27

15186 J. Henderson. Improved furnace or grate bars. May 7

1887.

3118 E. Luck. Distilling apparatus. April 27

3647 C. H. Roeckner, F. L. Roeckner, and E. L. Roeckner. Apparatus for separating solids from liquids, and for filtering liquids. May 4

---

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

4425 H. E. Newton—From W. Bauer. Filter presses. May 18

4587 J. Waters. Steam generators and furnaces therefor. April 30

4588 J. Waters. Steam generators. April 30

4600 C. F. Dahl. Furnace for recovering, in an inodorous manner, the salts contained in the lyes used in the manufacture of wood fibre. April 30

4626 C. A. Koellner. Filter pumps. May 18

4976 J. V. Wilson. Pans for heating oil or other liquids, and apparatus for passing air or gases through liquids, and agitating liquids in pans and similar vessels. May 7

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

5986 G. Beal, Liverpool. Lime coal fuel. Converting coal dust into blocks at small cost, producing great heat, and almost smokeless. April 25

6018 A. J. Boult—From D. Macdougald Kennedy, Canada. Improvements in the purifying of hydrocarbon oils. Complete specification. April 25

6039 R. Haddan—From M. Vaillant-Dubus, France. Improvements in or relating to the heating of air by boiler furnaces, and other means of heating. Complete specification. April 25

6061 J. Balbirnie. See Class I.

6064 W. Hanson, Middlesbrough. Improvements in coke ovens. April 26

6239 O. Imray—From C. A. von Welsbach, Austria. Treatment of incandescence bodies formed of metallic oxides for increasing the luminosity and resisting properties thereof, and apparatus for that purpose. April 28

6274 W. Wakefield, London. An improved method of and apparatus for generating vapour or gas from oil, together with burners for burning the same in lighthouse and other lamps. Complete specification. April 29

6342 G. Downing—From T. Baur, Germany. Improvements in coke ovens. April 30

6348 B. Pitfard, London. Improvements in the manufacture of appliances to be rendered incandescent by heat. April 30

6421 H. Hall, London. Improvements in machinery for the manufacture of artificial or patent fuel May 2

6475 S. Willoughby, London. Improvements in candles. May 3

6520 J. Hargreaves, Liverpool. Improvements in and apparatus for promoting the combustion of liquid fuel. May 4

6596 G. Johnstone, Glasgow. Improvements in apparatus for lighting railway trains with gas. May 5

6598 J. C. Bent, Birmingham. Improvements in incandescent gas fires, or gas heating apparatus for domestic purposes. May 5

6635 R. N. Clifford, Birmingham. A new perforated block fire-lighter. May 6

6650 J. Pointon, Liverpool. The better securing the perfect combustion of gas or vapour of petroleum, and the utilisation (1) of the evolved heat in the generation of steam; (2) of the products of combustion. May 6

6652 B. H. Thwaite, Liverpool. Improvements in methods of combustion of oil spray or gas from liquid hydrocarbons for illuminating purposes, and in apparatus therefor. May 6

6701 E. Zohrab, London. An improved method of and apparatus for the treatment of peat. May 7

6771 J. Lyle, Glasgow. Improvements in and connected with the burning of oils or other hydrocarbon fluids as fuel in furnaces. May 9

6818 H. Williams, Stockport. Improvements in the method of generating inflammable gaseous vapour applicable for heating, lighting, and actuating power, and apparatus therefor. May 10

6915 G. K. Cooke, London. A method of superheating and burning illuminating gas, and apparatus in connection therewith. May 11

6979 D. W. Sugg, London. Improvements in apparatus for lighting by gas. May 12

7067 W. H. Beck—From A. Kreiger, France. New or improved automatic apparatus for the production of carburetted air gas. May 14

7071 J. Birchall, Liverpool. Improvements in or connected with steam generators heated by gas, partly applicable to other heating purposes. May 14

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

7317 T. Christy. Regulating the heat of hot air chambers. May 18

8312 P. Farinaux. Apparatus for manufacture of carbonic acid and other gases. May 11

8319 A. M. Clark—From G. E. Wery. Consuming smoke and economising fuel in furnaces and fireplaces. April 27

8184 G. Symes. Purification of gas, and impregnation of same with hydrocarbon or other vapour, and apparatus therefor. April 30

8709 A. Paget. Manufacture and application of "mantles" in incandescent gas lighting, and packing such mantles. May 7

8761 W. C. Haigh and A. A. Haigh. Artificial fuel. April 27

1887.

281 J. Parkes and J. Parkes. Carburetting apparatus. April 27

927 S. Levy—From G. H. Kohn. Manufacture of water gas and other gases for lighting and heating, and apparatus therefor. May 4

4687 A. A. Harwood and M. D. Van Tassel. Apparatus for generating gas. May 7

4784 H. B. Sheridan and E. Rawlings. Apparatus for the manufacture of gas. May 4

4888 F. Friedlander and J. Quaglio. Obtaining hydrocarbons from gases. May 11

5313 H. Cockey and F. C. Cockey. Gas washers. May 11

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATIONS.

5785 A. A. Yale—From The Chemische Fabriks Actien Gesellschaft, Hamburg. Process for the purification of crude anthracene. Complete specification. April 20

5824 J. W. Knights and W. D. Gall, London. Improvements in the manufacture of carbolic acid and other tar acids. April 21

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

5729 W. R. Hodgkinson—From M. Conrad and L. Limpach Bavaria. An improved process for the preparation of γ-oxychineldine and its derivatives for use in the preparation of dyestuffs and for other uses. April 20

5896 A. Kern, London. Improvements relating to the manufacture of sulpho-nitrosulpho, nitrosulpho, and amidosulpho acids, and to their application for the production of new colouring matters. April 22

5953 A Kern. Improvements relating to the preparation of the methylic ether of gallic acid, and to the manufacture of purple colouring matters therefrom. April 23

6687 C. D. Abel—From The Actiengesellschaft für Anilin-Fabrikation, Germany. Processes for the production of azo-colours that dye cotton direct from a soap bath. May 6

6688 C. D. Abel—From The Actiengesellschaft für Anilin-Fabrikation. Processes for the production of yellow, orange, and red colours by the action of phenanthrene-chinone, isatine, or methyle-isatine upon the sulpho-acids of aromatic hydracines. May 6

7116 A. Ewer and P. Pick, London. Process of obtaining products of condensation from aldehydes and the sulphuric acids of the aromatic amines, and also compounds of the same with tetrazo-compounds. May 16

COMPLETE SPECIFICATION ACCEPTED.

1886.

8992 C. D. Abel—From The Farbwerke Vormals Meister Lucius and Bruning. Production of green colouring matters. May 7

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

5685 A. J. Boult—From E. H. M. Caston, Canada. Manufacture of merchantable material from thistledown. April 19

6121 E. M. Serrell, jun., Paris. Process and machinery for the mechanical "debavage" or cleansing of cocoons after brushing. Complete specification. April 27

6208 J. D. Sutcliffe and B. T. O'Brien, Manchester. Improvements in apparatus applicable for drying cotton and other fibrous or granular material. April 28

6433 J. Elce, Manchester. Improvements in machines for opening and cleaning cotton and other fibre, parts of said improvements being applicable for other purposes. May 3

6461 C. C. Kauffman, London. Improvements in the process of and apparatus for treating ramie, jute, and other fibres. May 3

6480 W. H. Stead, Liverpool. Improvements in the treatment of cotton seed for the removal of fibrous matter therefrom, and in apparatus therefor. May 3

6726 P. Bairstow and J. Bairstow, London. Improvements in the method of and apparatus for distributing oil or other liquids upon wool and other fibres whilst being fed to drawing-frames, combing and other machines. May 7

COMPLETE SPECIFICATION ACCEPTED.

1886.

W. R. Lake—From C. Orlay. Rendering textile fabrics, etc., impermeable, and protecting them from injury by moisture. May 18

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

6131 A. C. Lewis, Bradford. A new method of dyeing warps. April 27

6565 O. Delhaye, London. A new or improved process of dyeing vegetable or animal fibres. May 4

6721 T. A. Crook, London. Improvements in machines employed in bleaching, dyeing, printing, and finishing woven fabrics, or analogous operations. May 7

6737 C. Collin and L. Benoist, London. A new process for fixation of colouring matter by oxidation at high temperature of the textile fibres. Complete specification. May 7

7021 C. H. Behnisch, Luckenwalde, Germany. Improvements in the method of and apparatus for producing patterns or designs on cloth and other fabrics. Complete specification. May 13

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

9286 F. A. Gatty. Dyeing wool or other animal fibres in the raw or manufactured state. May 18

16780 J. H. Lorimer. Treatment of wool, cotton, paper, etc., for bleaching, colouring, disinfecting and drying the same, and apparatus therefor. May 4

1887.

113 G. Jagenburg. Process and apparatus for dyeing unspun textile fibres. May 11

4365 E. Booth—From W. A. Fourness. Apparatus for dyeing loose or spun fibres. April 27

4761 G. Jagenburg. Method and apparatus for mordanting, dyeing, and bleaching raw cotton. May 1

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

5711 W. S. Squire, London. Improvements in the manufacture of sulphuric anhydride. April 19

5753 T. T. Mathieson and J. Hawliczek, Liverpool. Improvements in the manufacture of carbonate of soda or soda ash, and in apparatus therefor; partly applicable for other purposes. April 20

5757 T. T. Mathieson and J. Hawliczek. Improvements in the manufacture of caustic ash. April 20

5853 E. W. Parnell and J. Simpson, Liverpool. Improvements in the utilisation of sulphate of lime and sulphate of baryta in the manufacture of alkalis and sulphuretted hydrogen. April 22

5854 E. W. Parnell and J. Simpson. Improvements in the production of sulphide of ammonium, and in apparatus therefor. April 22

6029 W. N. Hartley and W. E. B. Blenkinsop, London. Improvements in the manufacture of metallic sulphates. April 25

6107 H. Gardner—From R. J. Henderson, United States. Separation of carbonic oxide from nitrogen, carbonic acid, hydrogen, and other gases contained in the gaseous mixture resulting from the incomplete combustion of coal and of coke by the use of the chlorides of copper and of iron. April 26

6209 R. L. Hickes, London. Combining disinfectants with soda crystals. April 28

6417 J. Marx, London. Improvements in the manufacture of alkalies. May 2

6718 H. Grimshaw and H. Kenyon, Manchester. Improvements in the manufacture or production of zinc and other sulphides; in the utilisation of residual or waste products therein, and in apparatus therefor. May 7

6909 C. F. Claus, Wimbledon. Improvements in processes for obtaining sulphur from iron pyrites, copper pyrites, zinc blende, and other metallic sulphides. May 11

7011 J. Fleischer and C. Muhlich, Paris. Improved valve for liquid carbonic acid. Complete specification. May 13

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

872 P. Thomas. Apparatus for producing sulphurous acid in solution. April 23

6573 R. Weiss. Production of alumina compounds applicable for bleaching. May 18

8018 M. von Neucki and C. Kolbe. Manufacture of salicylic acid "esters." April 23

8217 J. H. Dennis and N. Glendinning. Obtaining sulphide of zinc from solutions. April 23

8308 L. Mond. Obtaining chlorine. May 7

8312 P. Farinaux. See Class II.

8723 E. Solvay. Process for the simultaneous manufacture of assimilable phosphates and of sulphate of ammonia. May 11

9366 O. Imray—From La Société Anonyme pour l'Etude de la Création de Soudières. Apparatus employed in the ammonia soda process. May 7

1887.

329 O. von Gruber. A process for manufacturing the double sulphate and phosphate of ammonium or potassium. April 30

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

5698 S. H. Rowley, London. An improved mode of preparing articles of pottery or glass to receive metal pipes or other metal connections. Complete specification. April 19

5701 J. Armstrong, London. Manufacturing rolled glass, and machinery therefor. April 19

5723 S. Pitt—From G. Falconnier, Switzerland. Improvements in the manufacture of building materials from glass, and in the application of the same. Complete specification. April 19

5769 B. Hartland, London. Firebricks made of an improved combination or mixture of earthy materials. April 20

5866 J. Blair, London. Improvements in china and crockery ware. Complete specification. April 22

5901 J. D. Doulton, London. Improvements in earthenware blocks and tiles, and in the manufacture of the same. April 22

6283 A. Murray, London. An improvement in the manufacture of bricks, mouldings, ridges, and other articles of clay used in building. Complete specification. April 29

6398 H. J. Burton, London. A machine for coating surfaces of glass, paper, metal, or other suitable materials, with solutions of gelatine or emulsions of chemical salts or finely-divided pigments. May 2

6412 J. B. Germeual-Bonnaud, London. Improvements in decorating glass, porcelain, or other ceramic ware with impressed designs. May 2

6477 W. P. Thompson—From M. C. Stone, United States. Improvements in the ornamentation of glazed earthenware articles. Complete specification. May 3

6502 R. N. Langton, London. Improvements in the manufacture of cups, saucers, and other articles for domestic and other purposes. Complete specification. May 3

6513 A. W. Itter, London. Improvements in the method of facing bricks, tiles, and other analogous articles. May 3

6616 L. C. A. Marguerie, London. A novel vitro-metallic material suitable for glazing, and for other purposes in place of glass. May 5

6634 F. Mitchell and C. Mitchell, Guildford. Improvements in cutting-off table whereby the punching of holes and cutting-off in the making of tiles, and other clay goods, is effected in one operation. May 6

6691 T. Sutcliffe, London. Improvements in tools for shaping the mouths of earthenware or stoneware bottles, jars, and the like. May 7

6758 W. R. Renshaw, Kidsgrove. Improvements in printing as applied to earthenware, china, and glass. May 9

6769 T. Stanway, Hanley. A new or improved means of decorating or ornamenting china, earthenware, glass or other suitable surfaces. May 9

6779 W. Lutwyche—From J. Valère, Paris. Ornamenting glass and other vitrifiable substances by means of translucid and opaque enamels in relief—Valère's translucid enamel in relief on glass, etc. May 9

7038 L. Boissonnet, London. Improvements in furnaces for burning pottery. May 13

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

3803 F. J. Frenzel, jun. Encaustic tiles. May 11

4821 E. Moore. Manufacture of opaque glass of a certain new colour. May 18

4822 E. Moore. Manufacture of opaque glues of a new colour. May 4

5129 F. Wallbrecht. Manufacture of bricks, tiles, and all kinds of earthenware. May 18

7338 E. Picard. Manufacture of glass. May 1

7438 E. Kerry and E. C. Kerry. Improvements in bricks. May 1

8067 P. J. Milligan. Manufacture of bricks. May 7

8339 R. Steinau. Improvements in facing bricks and manner of setting same. May 1

8477 W. Kent and C. Cope. Apparatus for working or mixing plastic materials, such as potters' clay. May 4

9226 H. H. Lake—From M. P. H. Bécoulet and L. J. O. Bellet. Manufacture of sheets or plates of glass, and other articles. May 4

10574 A. Drummond. Manufacture of glass, and application of same to roof lights, etc. May 11

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS

APPLICATIONS.

5814 T. H. Lodge, London. Improvements in the method of and means or apparatus employed for drying "slip" or "slurry," from which Portland cement is produced. April 21

5815 T. H. Lodge. Improvements relating to the manufacture of Portland cement, and in apparatus employed in connection therewith. April 21

5816 T. H. Lodge. Improved method of and means or appliances connected with the utilisation of the hot waste gases from cement and other kilns for the production of steam power. April 21

6038 G. H. Sharpe, F. W. Turner, and E. Mesnard, London. Improved manufacture of cement suitable as plaster, and for moulding purposes. April 25

6110 G. F. Redfern—From F. Martin, France. Improvements in limekilns. May 2

6701 B. H. Thwaite, D. L. Collins, and D. Wilson, Liverpool. Improved method of manufacturing Portland cement, and apparatus therefor. May 7

6802 J. Hoyle, London. Improvements in burning cement and lime, and in kilns for the same. May 9

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

2573 P. Jochum. Apparatus for mixing and preparing pulverulent argillaceous and other materials. May 11

6212 E. Edwards—From C. Hubert and H. Gennari. Apparatus for forming compressed blocks for building and other purposes. May 7

7511 M. M. Brophy and J. A. Archer. Manufacture of transparent material for roofing, etc., and apparatus therefor. May 11

7888 F. W. S. Stokes. Manufacture of cement in a powdered state, and apparatus therefor. May 11

8177 W. Kent and C. Cope. See Class VIII.

10167 P. Feserich. A new or improved artificial asphalt and process for manufacturing the same. May 4

13205 J. D. Denny. Terra cotta building blocks, and appliances for making same. May 18

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

5697 J. Abbott, London. Improvements in "pots" for tinning plates, and in apparatus connected therewith. April 19

5727 A. Wilson, London. Improvements in apparatus for manufacturing compound plates of iron and steel. April 19

5781 Viscount d'Hauterive, London. A process for producing an unoxidisable coating on iron and steel. April 20

5811 G. Elias, London. Improvements in the production of terne and tin plates, and in machinery or apparatus therefor. April 21

5951 R. Low, London. An improved process or method of hardening or tempering steel projectiles. April 23

6028 A. Schanschieff, Norwood. Improvements in miners' safety lamps, to enable them to indicate the presence of fire-damp. April 25

6635 C. Morris and G. Birkbeck, London. Improvements in the manufacture of terne plates. April 25

6058 B. H. Thwaite, Liverpool. Improved methods of casting steel and other metals, especially applicable to the casting of projectiles, heavy ordnance, and like material. April 21

6086 S. P. Thompson, London. Improved processes in electro-deposition. April 26

6087 E. D. Wassell, London. Method and means for reducing the point in carbon in steel, and forming a homogeneous weld. Complete specification. April 26

6109 A. J. Mashrey and P. S. Phillips, London. Apparatus for the manufacture of tin and terne plates. April 26

6117 G. B. Williamson—From H. F. Logan, New Zealand. Improvements in smelting crude antimony. April 27

6120 W. Patterson, Durham. Improvements in miners' safety lamps. April 27

6157 T. Hussey, Northwold. Armour-plating for vessels of war and other purposes. April 27

6165 R. S. Casson, London. Improvements in the manufacture of steel or ingot iron and phosphate of lime. April 27

6173 R. A. Hadfield, London. Improvements in the treatment of steel. April 27

6286 J. Colley, London. Improvements in moulds adapted for use in the casting of metals. April 29

6287 W. Bevitt, Romford. Radiating gold amalgamator. April 29

6367 C. Burnett, Hartlepool. An improved system of boring long holes in coal mines. May 2

6368 A. Reaney, Sheffield. Improvements in the manufacture of projectiles for piercing armour-plates, etc. May 2

6370 S. Toussaint, Paris. Process and apparatus for extracting the tin from tinned iron cuttings or scrap, and from metal covered with tin. Complete specification. May 2

6487 R. L. Short, J. Short, and J. B. Short, London. A safety lamp for use of miners and others. Complete specification. May 3

6536 R. Chapman, sen., and R. Chapman, jun., London. Improvements in glasses for miners' safety lamps. May 4.

6569 J. E. East, London. Improved means or appliances for employment in close annealing iron and steel sheets, and other parts or articles of metal. May 4.

6633 W. H. Osborn, Birmingham. Producing by electro-deposition ornamental designs and lettering on plates of metal. May 6

6703 E. Zobrab, London. An improved method of case-hardening, or converting into steel the surfaces of iron plates and other objects made of iron. May 7

6719 E. Morewood, London. Improvements in coating plates or pieces of iron, steel, or other metal with tin, terne, zinc, or other metals. May 7

6757 C. Kaberry and L. Hope, Liverpool. Improvements in safety lamps. May 9

6768 C. Bramall, Oughtibridge. An improved portable combined smelting and converting furnace, and apparatus employed therein. May 9

6900 J. Willis, Sheffield. Improvements in the manufacture of armour-plates, shot, and shell. May 11

6916 W. Baker and J. Barton, London. Improvements in miners' safety lamps. May 11

6913 M. Settle, Manchester. Improvements in magneto-electric machines employed for firing explosive charges for mining and other purposes. May 12

6991 H. Trautmann, London. Improvements relating to the plating or coating of wood, leather, and other articles or materials with metal by electro-deposition. May 12

7013 D. Appleton and F. A. Binney, Manchester. Improvements in electro-plating rollers and other articles. May 13

7017 A. P. Vivian, London. Improved manufacture of metallic alloys. May 13

7068 J. Marsh, H. P. Marsh, and J. P. Marsh, Sheffield. Improvements in the manufacture of self-hardening steel, and in making tools of same. May 14

7139 D. Edwards, R. Lewis, and P. Jones, London. Improvements in apparatus for coating metal plates with tin or other metal. May 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

6790 C. Burnett. Machines for drilling, boring, etc. May 18

8367 T. Nicholson. Machinery for crushing minerals. May 18

8387 G. Francis. Tamping blast holes in mines and other places. April 27

8390 R. Heathfield. Apparatus for coating sheet-iron with zinc, or alloys of zinc, or other coating metal or alloy. April 27

8531 F. J. R. Seaver—From E. C. Kleiner-Fiertz. Manufacture of aluminium and other light metals. May 4

8885 H. Boyns. Improvements in, and apparatus for, dressing minerals. May 11

9113 C. R. Whittaker. Safety lamp for use in mines. May 11

9382 B. C. Tilghman. Straightening, stiffening, drawing, and rolling metal bars. May 18

10127 E. Schroder and H. Perner. Preparing a metallic covering for giving a non-oxidising or only slightly oxidising covering to wood, etc. May 11

10477 W. A. Thoms. See Class XVIII.

10823 J. Y. Johnson—From La Compagnie Anonyme des Forges de Chatillon et Commentry. Tempering or hardening metal. May 11

14265 R. Stewart and J. F. Waldie. Washing coal, etc., and apparatus therefor. May 7

15322 E. C. Kleiner-Fiertz. Manufacture of aluminium and other light metals. April 27

16286 J. Craven and W. Chapman. Foundry ladles for pouring molten metal. May 4

1887.

921 C. D. Abel—From E. Fischer and M. W. Weber. Extracting gold and other precious metals from their ores, and apparatus therefor. April 23

4576 D. G. Reillon, S. T. Montagne, and O. L. B. L. Bourgerel. Extracting aluminium from alumina. April 30

4609 J. C. Newbery and C. T. J. Vautin. Wet or hydrometallurgical method of extracting gold from crushed or other finely-divided ore. May 4

4664 W. P. Thompson—From E. H. Cowles and A. H. Cowles. See Class XVIII.

1562 E. Dunkley and A. Dunkley. Method of making leather waterproof or flexible. May 18

XI.—FATS, OILS, AND SOAP MANUFACTURE

APPLICATIONS.

5960 S. Schofield, Bradford. A process for extracting oil or other lubricants from greasy waste or cleaning cloths, and for making the extracted grease into soap. Complete specification. April 23

6756 T. Turner, Preston. An improved method for filtering spent or other oils. May 9

6986 W. Sanzenbacher and S. Tanatar, London. Method and apparatus for distilling fatty acids by means of superheated steam. Complete specification. May 12.

7117 J. Thomson, London. Improvements in the composition of mercurial soaps. May 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

6736 J. S. Edwards. Treatment of fish, etc., to extract oil or fat therefrom, and apparatus therefor. May 11

8756 R. Tervet and F. Alison. Treating and purifying paraffin wax, and apparatus therefor. May 7

XII.—PAINTS, VARNISHES, AND RESINS.

APPLICATIONS.

5791 F. Crane—From J. Hale, United States. An improved compound or varnish for coating metal, wood, and other materials. April 20

6291 J. H. Jackson, London. The universal liquid and metallic enamel bronzes. April 29

6323 W. L. Wise—From R. Lehmann, Germany. Improvements in apparatus for the manufacture of oil-lac Complete specification. April 30

6582 P. Molyneux, London. An improved paint or coating. May 4

6619 J. C. Martin, London. Improvements in treating or imparting body or opacity to sulphate of baryta and other sulphates and substances, and the manufacture from materials so treated of white and tinted or coloured pigments. May 5.

6671 S. Banner, Liverpool. Improvements in treating resins, oleo-resins, gums, pitches, varnishes, bitumens, tars, oils, fats, and other hydro-carbonaceous matters, and in products obtained therefrom (in combination with other substances). May 6

6697 J. Wilson, Leith. Making sulphide of zinc paint. May 7

6755 H. A. Harvey, Liverpool. Improvements in compositions for coating the bottoms of navigable vessels, and the submerged portions of floating and other structures. May 9

6870 H. H. Lake—From E. N. Todd, United States. Improvements in compositions for the manufacture of articles by moulding, carving, or turning, or of varnish and lacquer, and for similar purposes. Complete specification. May 10

6937 R. Ripley, Liverpool. Improvements in paint or colouring for metal-work, stone-work, stucco, and other surfaces. May 12

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

9581 J. B. Hannay and E. J. Pape. Making white paint May 18

1887.

4334 T. Kenyon. Preparation of pigments, and treatment of bye-products therefrom. April 27

XIII.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

5741 H. House, Leeds. Improvements in the manufacture of artificial leather from leather waste and scraps, and in the utilisation of the same, and in machinery employed therefor. April 20

6116 J. Palmer, London. A new and improved process for softening and unhairing, or unwooling hides or skins. April 27

6412 G. Delfos, London. A method of treating goat skins. May 3

6914 J. S. Hooper, London—From J. W. Darrow, United States. An improved method for treating hides and skins for leather and other purposes. May 11

6958 J. Campbell, Glasgow. Improvements in making glue. May 12

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

5619 J. Hall and A. Hall. Machinery employed in the manufacture of leather for setting, scouring, striking, printing, rolling, slicking, fleshing, unhairing, whiting, shaving, and brushing. May 14

8582 A. J. Boult—From Count V. de Nydprüek. Improvements in tanning. April 30

11683 J. W. Abom and J. Landin. Tanning hides and skins. May 14

XIV.—AGRICULTURE, MANURES, Etc.

APPLICATIONS.

6632 W. L. Wise—From E. Solvay, Belgium. New or improved processes for converting natural and other phosphates into products assimilable by vegetables, and into valuable sub-products. May 5

6813 F. Knauer, London. Improved method for enriching seed plants with alimentary substances. May 10

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

8723 E. Solvay. See Class VII.

9636 L. A. Chevalet. Process for manufacturing neutral phospho-guano. April 23

XV.—SUGAR, GUMS, STARCHES, Etc.

APPLICATIONS.

5660 J. Thomson and J. Black, Glasgow. Improvements in or connected with sugar cane mills. April 19

6100 G. Epstein, London. Improvements in the treatment of diastase and other material or products. April 26

6261 J. Buchanan, jun., Liverpool. Improvements in apparatus for drying and granulating sugar, salt, and like substances. April 29

6431 S. Vickess, Liverpool. Improvements in apparatus for cutting or dividing sugar or like friable substances into blocks or cubes. May 3

6875 A. M. Wood, London. Improvements in the treatment of indiarubber, caoutchouc, gutta-percha, and analogous gums. May 10

6936 P. J. E. Heffter, Germany. Improvements in the method of clarifying and saturating sugar solutions, especially beet-root rob, by means of tannic acid or tannin. May 12

7087 W. R. Watson—From A. Young, Hawaiian Islands. Improvements in the manufacture of sugar, and in the apparatus used in connection therewith. May 14

7119 C. Steffen, London. An improved process for systematically lixivating raw sugar by means of aqueous alcoholic or other saccharine solutions. Complete specification. May 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

9216 C. Lyle and J. Lyle. Manufacture of lump sugar. May 7

10911 P. Labèrie. Apparatus for evaporating the juice of beet-root, sugar cane, etc. May 11

1887.

602 R. A. Robertson and J. G. Hudson. Sugar cane mills. May 4

XVI.—BREWING, WINES AND SPIRITS.

APPLICATIONS.

5759 C. Last, London. Improvements in malting houses and kilns. April 20

7008 W. Smith and W. Bagshaw, Dudley. Apparatus for skimming or removing barm or yeast from ale, beer, or other fermented or fermentable liquors. May 13

COMPLETE SPECIFICATION ACCEPTED.

1886.

9090 A. W. Gillman and S. Spencer. Apparatus for the preparation of finings for the use of brewers. May 7

XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, Etc.

APPLICATIONS.

A.—Chemistry of Foods.

5708 J. F. O. Qvistgaard, London. Apparatus for heating milk prior to separating the cream therefrom, also applicable for destroying germs therein, and for heating other liquids. April 19

6003 R. Jones, London. An improved method of preserving animal and vegetable substances for the good of man. April 25

6025 W. H. Gilruth, London. An improvement in, or connected with, the process of withering, firing, or curing tea. April 25

6073 R. E. Phillips, London—From C. P. N. Martin, Ceylon. Improvements in drying ovens for drying tea, and for analogous uses. April 26

6096 A. G. Wass, London. An improved food for animals. April 26

6285 A. Leerbeek and J. Holm, London. An improved process for producing albumen-maltose dietary malt powder for food. Complete specification. April 29

6401 H. B. Thornton, London. An improved method of preparing and preserving a mixture of tea, coffee, or other substance used for the making of beverages in combination with milk and sugar. May 2

7112 D. Ker, London. Improvement in manufacturing cocoa in any form, from the nib cocoa to the prepared cocoa, a paste, a powder, and the flaked cocoa; all soluble in warm water. May 16

B.—Sanitary Chemistry.

5655 G. E. Davis, Manchester. Softening and purifying water for domestic and trade purposes. April 19

5661 G. E. Davis and J. B. Aitken, Manchester. Treating or purifying sewage, waste liquors from manufactories, and other foul liquids, and producing valuable substances therefrom. April 19

6068 R. Nicholls, London. Improved means applicable for the purification of sink water and for like purposes. April 26

6665 B. C. Badham, London. Certain improvements in, and apparatus for, purifying gases arising from sewers, surface water drains, closets, and other places. May 6

7072 W. J. Lomax and M. Guthrie, London. Extracting gas, oil, fatty and other matters from sewage sludge and similar deposits, and apparatus therefor. May 14

C.—Disinfectants.

6037 A. Dickson Hunter, London. Improvements in compositions for treating matters having an offensive smell. Complete specification. April 25

6085 T. Hallsworth and R. Bailes, London. Improvements in or relating to disinfecting powders or compounds. April 26

6209 R. L. Hicks, London. Combining disinfectants with soda crystals. April 28

6571 J. W. Hamilton, Liverpool. Improvements in or relating to disinfectants. May 4

COMPLETE SPECIFICATION ACCEPTED.

A.—CHEMISTRY OF FOODS.

1886.

9712 E. R. Allen and W. C. Allen. Manufacture of articles of food from the kernels of almonds and other fruits. April 30

XVIII.—ELECTRO-CHEMISTRY.

APPLICATIONS.

5687 W. P. Thompson—From H. W. Spang, United States. Improvements in fusible connections for armatures for electric generators. Complete specification. April 19

5709 A. J. Gravier, London. Improvements in dynamo-electric machines. April 19

5720 C. Coerper. Improvements in dynamo-electric machines. April 19

8867 W. Kingsland, London. Improvements in secondary batteries. April 22

5955 G. E. Dorman, Stafford. Improvements in the manufacture of thermo-electric elements or chains. April 23

5958 A. M. Clark—From L. Maiche, France. Improvements in dynamo-electric and magneto-electric machines. April 23

6273 J. T. Armstrong, London. Improvements in the manufacture of porous plates and cells for electrical batteries. April 29

6294 A Watt, London. Improvements in the electrolytic treatment of zinc and its ores. April 29

6409 R. E. Bell and W. A. Kyle. Improvements in dynamo-electric machines and motors. May 2

6623 W. H. Tasker, London. Improvements in the manufacture of plates or elements for voltaic batteries. May 5

6681 R. E. B. Crompton, Chelmsford, and J. C. Howell, Llanelly. Improvements in secondary batteries or electrical accumulators. May 6

6711 F. von Harotmuth, London. Method and apparatus for the manufacture of carbon rods for electric arc lights. May 7

6754 R. E. B. Crompton and J. Swinburne, Chelmsford. Improvements in and connected with dynamo-electric machines. May 9

6805 G. Philpott and M. C. Stapylton, Brighton. An improvement on the electrical secondary generator. May 10

6828 E. T. Higham and D. Higham, London. Improvements in the regulation of dynamo-electric machines. Complete specification. May 10

6829 P. Jensen—From O. Lugo, United States. Improvements in electric batteries. Complete specification. May 10

6869 H. H. Lake—From W. J. Ludlow, United States. Improvements in and relating to primary and secondary batteries. Complete specification. May 10

7021 G. Scarlett, Liverpool. Improvements in electro-dynamic and dynamo-electric machines. May 13

7030 C. Maltby-Newton, High Wycombe. An improved construction or formation of plates with composition for electric batteries. May 13

7059 R. W. Paul, London. Improvements in electrical accumulators and primary batteries, and means for effecting the same. May 11

7093 W. G. Spurgeon, London. Improvements in the containing jars or cells of primary or secondary batteries. May 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

5817 S. F. Walker. Galvanic batteries. May 4

5855 F. W. Benson. Improved galvanic battery. May 4

7561 J. Gibson and F. M. Gibson. An improved electrode. May 7

7818 C. Smith. Secondary batteries. April 23

7953 W. Geipel. Method of regulating currents generated by dynamo-electric generators. April 27

8003 L. B. Atkinson, T. Goolden, and A. P. Trotter. Dynamo-electric generators. May 4

8226 A. M. Clark—From A. E. Peyrusson. Secondary batteries. April 23

8197 A. T. St. George. Apparatus for generating electricity. April 30

8620 G. E. Dorman. Thermo-electric batteries. May 4

8832 A. Schanschieff. Saline preparation applicable for use in galvanic batteries, and process for manufacturing same. May 11

9056 W. Maxwell. Construction of dynamo-electric machines. May 11

10177 W. A. Thoms. Deposition of platinum by electricity. April 30

1887.

4219 C. Desmazures. Improvements in accumulators of electricity April 23

4527 L. Epstein. Electrodes for primary or secondary batteries. May 14

4571 W. E. Heys—From J. Beattie, jun. Construction of zines for galvanic batteries. April 30

4664 W. P. Thompson—From E. H. Cowles and A. H. Cowles. Electric furnaces applicable for making aluminium, and for other purposes. April 30

4667 W. P. Kookogey. Galvanic battery solutions. April 30

4744 H. J. Harris. Supporting elements in batteries. May 4

4931 M. Bailey and J. Warner. Improved battery and method of regulating same. May 4

XIX.—PAPER, PASTEBOARD, ETC.

APPLICATIONS.

5805 P. M. Crane and F. Wilkinson, Manchester. Improvements in the manufacture of corrugated paper and analogous materials or fabrics. April 21

6174 F. Voith, London. Improvement in engines or machines for the manufacture of paper pulp. April 27

6897 G. Hibbert, Gateshead. Improvements in apparatus for straining pulp used in the manufacture of paper. May 11

7052 W. O. A. Lowe, Liverpool. Improvements in the manufacture of paper, cardboard, or flexible sheets. May 11

7090 T. Phœnix, Newcastle, and G. Kirk, Uttoxeter. Improvements in the manufacture of pottery tissue paper for transfer printing. May 11

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

5269 G. Pitt—From R. P. Pictet and G. L. Brelaz. Manufacture of paper from wood, and apparatus therefor. May 11

5296 L. Bastet. Manufacture of waterproof and combined water and fire-proof paper. May 11

7633 L. A. Groth—From H. Schnurmann and G. Closs. Manufacturing sulphite cellulose in beton boilers. May 7

7694 W. Hull and W. B. Walker. Beating or pulping machines applicable for paper making. May 11

8593 J. Luke. Treating or preparing paper for the manufacture of floor and wall coverings, etc. April 30

8936 E. Davies and H. F. Harris. Method and apparatus for treating spent hops for use in the production of pulp for paper and mill-board. May 11

9178 A. J. Boult—From A. Ubbelobde. Manufacture of paper pulp from moss peat. May 18

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

COMPLETE SPECIFICATION ACCEPTED.

1886.

8168 W. Merck. Production of peptone from nucleo-proteines. April 23

XXI.—EXPLOSIVES, MATCHES, ETC.

APPLICATIONS.

5803 F. P. Warren, London. An improved mode of attaching explosives to the sides or bottoms of ships. April 21

5877 A. Minter, London. An improved paint or coating for the formation of frictional surfaces for lighting safety and other matches. April 22

5883 F. W. Smith—From Messrs. Klee and Koecher, Germany. Improvements in the construction of exploding charges or cartridges. Complete specification. April 22

5899 P. M. E. Andouin, London. Improvements in explosives, and in the manufacture of the same. Complete specification. April 22

5987 M. A. Whitley, Bradford. Improvements in the manufacture of matches. April 25

NOTICES.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those members of Council whose names are placed in italics in the annexed list, will retire from their respective offices at the forthcoming Annual General Meeting.

Professor James Dewar, F.R.S., has been nominated to the office of President, and Mr. David Howard has been nominated Vice-President under Rule 11.

Professor Clowes, Mr. J. Neilson Cuthbertson, Mr. Ivan Levinstein, and Professor W. A. Tilden, F.R.S., have been nominated Vice-Presidents under Rule 8; and Mr. B. S. Proctor has been nominated Ordinary Member of Council under Rule 17, in the place of Mr. Levinstein, nominated Vice-President.

Mr. James Duncan, Mr. F. J. Rowan, Dr. Edward Schunck, F.R.S., Mr. T. W. Stuart and Mr. Frank Wilson have been nominated, under Rule 18, to fill four vacancies among the Ordinary Members of Council.

The Treasurer and Foreign Secretary have been nominated for re-election.

The Annual General Meeting of the Society will be held at 11 a.m. on Wednesday, 13th July next, in the Lecture Theatre of the Owens College, Manchester. Particulars as to visits to works and excursions are issued, together with the Ballot List and Member's Ticket in a separate cover. Members are particularly requested not to place any other communication whatever in the envelope provided for the return of the Ballot List, but to send word of the places they wish to visit to Mr. Carter Bell.

Comment having been made on the delay in reprinting the numbers for January, 1882 and 1883, the Secretary begs to inform those whom it may concern, that the delay is due to the fact that up to the present not more than twenty orders for those numbers have been received. It is hoped that this notification may stimulate those who desire to complete their sets, to make early application with a view to expedite the consideration of the question of reprinting by the Council. Notice is also hereby given that the numbers for January and February, 1886, being exhausted, no orders for those copies, nor for complete sets of Vol. V., can be executed.

Authors of communications read before the Society or any of its Local Sections are requested to take notice that, under Bye-Law 43, they cannot receive the prescribed 50 copies of their communications unless they comply with the condition laid down in that Bye-Law—viz., that they give notice of their desire to receive such copies upon their manuscript before sending it to the Editor. Mention should also be made as to whether the Discussion is to be included in the reprint.

CHANGES OF ADDRESS.

Cornelius Beringer; Journals, etc., to 293, Vauxhall Bridge-road, London, S.E.

H. Buckeridge, l/o Crouch End; Leighton Villa, Cheverton Road, Hornsey Lane, N.

G. Chaloner, l/o Green Lanes; 30, Weston Park, Crouch End, N.

P. de G. Coghill, l/o Kensington; 47, Derby Lane, Old Swan, Liverpool

J. H. Collins, l/o Highgate New Town; 4, Clark Terrace, Dulwich Rise, S.E.

C. S. Doggett, l/o Munich; Walpole, Mass., U.S.A.

R. F. Foster, l/o Cape Town; Caledon Dispensary, Uitenhage, South Africa.

Dr. H. H. Fries, l/o Berlin; 92, Reade-street, New York, U.S.A.

Edgar Hall, l/o Queensborough; Alexandria Cottage, Merlin Street, St. Leonard's, New South Wales.

W. F. Jack, l/o Neath; 45, Ludgate Hill, London, E.C.

F. Joynson, l/o Connah's Quay; Witton House, Northwich, Cheshire.

J. Lawrence, l/o Glasgow; Standard Explosives Co., Toms River, New Jersey, U.S.A.

D. McCalman, l/o Glasgow; 50, London Street, Irvine, N.B.

A. W. McIlwaine, l/o Oil Extracting Co.; Stone Ferry, Hull.

Dr. G. Harris Morris; Journals, etc., to Avondale, Alexandra-road, Burton-on-Trent.

J. S. North, l/o Cape Town; Caledon Dispensary, Uitenhage, South Africa.

I. I. Redwood, l/o Addiewell; Thorn House, Walthamstow, Essex.

F. J. Rowan, l/o St. Vincent Street; 121, West Regent Street, Glasgow.

M. Shimose, l/o Insatsukyoku; Heiki-Seizo-Sho, Akabanè, Tokyo, Japan.

Hugh T. Spencer, l/o St. Helens; 104, Thomas Lane, Broad Green, near Liverpool.

Jas. Towns, l/o Canning Town; 71, White Horse Street, Stepney, E.

G. M. P. Vary, l/o Edinburgh; communications to be retained until further notice.

H. G. Warner, l/o Ash; c/o Wallis and Milestone, Garratt Lane, Wandsworth, S.W.

A. W. Warrington, l/o Clapham; Dinglefield, Dingle Lane, Liverpool.

LIST OF MEMBERS ELECTED, JUNE 23, 1887.

Atkinson Crossley, Cambrian Chemical Co., Limited, Talywain, Monmouthshire, analyst.

Allan T. Hall, 1, Grosvenor Terrace, Beverley Road, Hull, oil and varnish manufacturer.

T. G. Hart, Royal School of Mines, South Kensington, S.W., research assistant.

A. Hoegger, Windsor Villa, Victoria Crescent, Eccles, Manchester.

J. H. James, 131, Hopton Road, Coventry Park, Streatham, S.W., mining engineer.

W. C. Matthews, Kerfeid Place, Albert Park, Melbourne, Australia, manufacturing chemist.

George Merrell, Lock Box 786, Cincinnati, Ohio, U.S.A., manufacturing chemist.

Jas. Oddie, School of Mines, Ballaarat, Australia.

David Perry, Forth and Clyde Chemical Works, Kirkintilloch, N.B., manufacturing chemist.

Dr. Otto Pring, Schwarzenberg, Saxony, editor of the *Chemische-technische Zeitung*.

D. Russell, Silverburn, Leven, Fife, N.B., paper maker.

Herbert B. Stocks, 13, Peet Street, Gladstone Road, Liverpool, chemical assistant.

Archibald Walker, 8, Crown Terrace, Glasgow, distiller.

Herbert W. Weld, 41, Albion-place, Mount Auburn, Cincinnati, Ohio, U.S.A., pharmaceutical chemist.

London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: David Howard.

Committee:

Sir F. A. Abel.

R. Messel.
B. E. R. Newlanda.
B. Redwood.
T. Royle.
John Spiller.
G. C. Trewby.
J. Williams.

Hon. Local Sec. and Treasurer: Thos. Tyrer, Garden Wharf, Church Road, Battersea, S.W.

The meetings of the London Section will be held on the first Monday in each month.

SESSION 1886–87.

Prospective Arrangements.

July 13, 14 and 15.—Annual Meeting in Manchester.

The meetings of the Session 1887—88 will be resumed on the 7th November next, and will be continued on the first Monday in each month.

FURTHER COMMUNICATION ON ENGLISH-GROWN TOBACCO.

BY ARTHUR WINGHAM, F.I.C., F.C.S.

In a previous communication the results of a few analyses and experiments in connection with some English tobacco, grown by Lord Harris, were laid before this Society. The present paper is a continuation of that communication, and contains the results of analyses of tobaccos grown elsewhere and under different conditions. The samples are four in number, and are numbered 8, 9, 10, 11. Nos. 8, 9, and 10 were grown by Mr. C. De L. Faunce de Laune, near Sittingbourne, and No. 11 by Mr. W. L. Wigan, near Maidstone. The following table shows the average measurements and weights of the leaves :—

	Length.	Breadth at broadest part.	Weight.
No. 8.	24 inches	10¼ inches	7·0 grammes
„ 9.	31 „	11 „	25·4 „
„ 10a.	24 „	12¼ „	18·0 „
„ 10b.	24 „	9 „	16·0 „
„ 11.	18 „	7 „	6·1 „

No. 8. Pale yellow leaves, very similar to Chinese tobacco. Uniform in colour, but lacked body.

No. 9. Large leaves of brown colour, varying in shade. Considerable body and very large mid-ribs and veins.

No. 10. Dull-brown leaves, varying in shade, shape, and size. Considerable body. This was a mixed sample of leaves that had been bulked for some considerable time. It contained two leaves (10b) which were of very good quality, good body, and uniform dull-brown colour; and seven leaves (10a) which were of a mixed character.

No. 11. Mixed sample—some leaves green, and others partly fermented. The fermented leaves were of a dull-brown uniform colour, with plenty of body. Very thick leaves.

The samples were dried at 100° C., and the moisture determined with the following results :—

No.	8	contained	20·7	per cent.	water.
„	9	„	21·4	„	„
„	10a	„	20·8	„	„
„	10b	„	18·8	„	„
„	11	„	14·0	„	„

Unfortunately there was not sufficient of 10b to examine separately, consequently it was mixed with the other portion of sample 10. The weight per square foot of these samples could not be ascertained with any possibility of certainty, on account of variation in shape in the same sample, and also of excessive corrugation in some cases.

The dried leaves were broken down, and the mid-ribs and thick veins removed. The remainder of the leaf, consisting of the fleshy part and the thin veins, was taken for analysis. The ash was first determined with the following results :—

PERCENTAGE OF ASH.

No. 8	21·35%	No. 10	23·23%
„ 9	17·98	„ 11	17·03

The samples burnt much more readily than the samples of English growth described in my previous paper, although there was still a slight difficulty in oxidising the last traces of carbon in No. 8. On first heating, an oil distilled off and burnt with a very luminous flame, especially in No. 9, which gave off a very large quantity. No. 11 evolved an oil which burnt with a less luminous flame, and also emitted objectionable odours, which were no doubt due to the presence of green unfermented leaves in the sample. Little or no self-supporting combustion was noticed, except in No. 10, which did continue to burn slightly when once ignited. The quantities of ash in Nos. 8 and 10 are high; Nos. 9 and 11 being fairly normal.

A complete analysis of the ash was then made in each case, with the following results :—

PERCENTAGE COMPOSITION OF ASH.

	No. 8.	No. 9.	No. 10.	No. 11.
Potash (K_2O)	9·52	9·30	10·14	11·32
Soda (Na_2O)	3·98	2·86	2·40	0·91
Lime (CaO)	37·59	41·41	39·22	35·83
Magnesia (MgO)	3·48	6·32	3·85	3·49
Iron Oxide and Alumina	0·68	0·58	0·56	0·70
Chlorine	9·15	8·70	8·42	9·68
Carbonic Acid (by diff.)	22·68	18·11	18·18	22·67
Sulphuric Acid (SO_3)	5·61	5·64	8·58	5·82
Phosphoric Acid (P_2O_5)	3·24	4·14	2·14	5·25
Silica	6·13	4·87	8·41	6·51
	102·06	101·96	101·90	102·18
Deduct ox. eq. for Cl	2·06	1·96	1·90	2·18
	100·00	100·00	100·00	100·00

It will be seen from the above figures that these ashes have the great fault which was also so marked in the samples of Lord Harris—viz., a high percentage of lime and a low percentage of potash, and the consequent high ratio of the former to the latter. One great advantage, however, that these ashes have over the Faversham samples, is the comparatively low percentage of chlorine. This lower quantity of chlorine would act favourably in rendering the burning of the leaf more easy. The higher percentage of silica is also favourable, although, at the same time, there is an undesirable increase in the sulphuric acid. Iron is also present in these ashes in small quantity.

Lithium was found spectroscopically in all four samples.

Compared amongst themselves, No. 11 may be taken as the best ash; although even this is not by any means of the composition most desired for tobacco. The lower percentage of lime, the higher potash and the higher phosphoric acid are all favourable items in No. 11 sample. No. 9, which was supposed to have been heavily manured with a certain guano, does not appear to differ materially, except in the phoshoric acid and magnesia, from the other samples, 8 and 10, grown in the same neighbourhood.

The total nitrogen in the leaves was determined as described in my previous paper, care being taken to have a large excess of copper oxide present. The following are the results :—

PERCENTAGE OF NITROGEN.

No. 8	9	10	11
3·23	5·71	5·29	6·54

There is a very decided difference between the samples in these figures.

The fleshy part of the leaf in each case was tested for nitrates. No. 8 contained none, while Nos. 9 and 10 contained considerable quantities. No. 11 contained none in the green leaves, but a considerable quantity in the brown leaves. This supports what was previously supposed to be the case—viz., that the nitrates present in tobacco are produced during the process of drying and fermenting.

The nitrate nitrogen was estimated in Nos. 9 and 10 by Schloesing's method of distillation with ferrous chloride and hydrochloric acid afterwards absorbing the nitric oxide by adding pure oxygen potash and pyrogallic acid. The following are the results :—

PERCENTAGE OF NITROGEN AS NITRATES.

No. 9	0·12 %	No. 10	0·31 %

These figures correspond to the following percentages of

POTASSIUM NITRATE IN THE LEAVES.

No. 9	0·86 %	No. 10	2·21 %

The presence of nitrates, I have found, however, is no indication of a good tobacco. It is true that saltpetre will convert a bad tobacco into a material that will smoulder, but in a good and well-fermented leaf the burning quality does not depend on the presence of nitrates. I have examined some of the best samples of foreign leaves, and have found only minute traces of nitrates present. The remaining nitrogen will be referred to hereafter.

The amount of soluble extract was then ascertained by heating weighed quantities with water at 80° C. for one hour, and weighing the dried residue. The following figures were obtained :

	No. 8	9	10	11
Soluble extract (by diff.)	55·95	58·70	52·15	49·84
Residue	44·05	41·30	47·85	50·16

The soluble matter is high in each case, especially so in No. 9, and slightly so in No. 11.

The ash in the residue was then determined and calculated into percentage on original leaf. In this way the following figures were obtained, showing :—

THE MINERAL CONSTITUENTS IN THE LEAF EXTRACTED BY, AND INSOLUBLE IN, WATER.

	No. 8	9	10	11
Ash extracted (by diff.)	17·26 %	14·29 %	13·04 %	11·42 %
Ash remaining in residue	7·09	3·69	10·19	5·61
	24·35	17·98	23·23	17·03

These figures speak very favourably for samples 10 and 11, and fairly well for No. 8, but they condemn No. 9 as being very immature. The superficial nature of the mineral constituents in this sample is very clearly shown, and the leaves, which are very large, are undoubtedly very artificial.

The nitrogen in the residue was also estimated, and the following results obtained :—

PERCENTAGE OF NITROGEN IN THE LEAF EXTRACTED BY, AND INSOLUBLE IN, WATER.

	No. 8	9	10	11
Nitrogen extracted (by diff.)	2·08 %	3·57 %	4·22 %	3·92 %
Nitrogen remaining in residue	1·15	2·14	1·07	2·62
	3·23	5·71	5·29	6·54

The nitrogen remaining in the residue roughly represents that which exists as albuminoids, as the following determinations of albuminoid nitrogen prove, except in the case of No. 10 :

PERCENTAGE OF ALBUMINOID NITROGEN.

No. 8	9	10
1·28	2·18	1·53

The figures in connection with No. 10 seem to point out the existence of albuminoids, not entirely precipitated by water at 80° C. Further experiments are being carried on to ascertain, if possible, the forms of combination in which the remaining organic nitrogen exists.

I intend also pursuing the subject of the organic constituents of tobacco, with a view to ascertaining the changes which take place during the process of fermentation, about which very little of a scientific nature seems to be known. I regret that in the report of the discussion of my previous paper, I am reported as having said that nicotine and nicotianine were not present in the unfermented leaves, and that they were produced during fermentation. I am sorry that I produced that impression. What I intended to convey was—that nicotine was probably not present in the green leaves as nicotine, but was probably there combined with other organic radicals in the form of a glucoside, or something of that nature, and that it was "released," and not "produced," during fermentation. But even this was only a surmise on my part, consequent upon a few peculiar results which I obtained in the earlier period of my investigation.

I think the above results, combined with those previously recorded, will now justify an expression of opinion as to the possibility of growing the tobacco plant in this country. There is not the slightest doubt about the mere growing; the only questions arising are the commercial ones, of its preparation for, and its value in the market. With the last question I will not trouble this Society, and as regards the preparation, or in other words the fermentation, I believe there is very little to fear. The natural difficulties are not so great as not to be within reasonable scientific reach. At present, one season's crop only has been experimented upon, but very important and promising results have been obtained. With the advanced knowledge and experience, I think another series of experiments will very nearly overcome the difficulty of fermentation. The analytical results obtained have pointed out one or two very great errors in the direction of the mineral constituents, and these certainly should be guarded against in the future. I do not desire to say that the quality of a tobacco can be ascertained from the analysis of its mineral constituents, any more than from the quantity of nicotine present, but I do maintain that the quality of its mineral constituents has a decided influence on the burning, and that a better attention to the supply of the natural requirements of the plant in this respect will most likely aid materially the development of the other good qualities. For that reason I have placed the mineral constituents first as regards importance, and in these samples have neglected to a certain extent the organic. The quantities of the mineral constituents present are on the average high, and with their present composition would tell very much against the tobacco, even if the fermentation were complete. It must be confessed that a calcareous soil is not the best on which to cultivate tobacco, but then, on the other hand, it can be argued that if, under existing circumstances, such good results have been obtained, then, under more favourable conditions, and with further experience, one can certainly expect very much more favourable results in the future.

The leaves which I have brought to your notice, both now and previously, are all somewhat immature, especially those in connection with my last paper. The large leaves grown at Sittingbourne are also of a very forced character, although they are very fine specimens, while the smaller and more compact leaves obtained near Maidstone seem to be of a much more natural growth. Whether the artificial nature of a leaf, as regards its organic constituents, is a disadvantage or not is an open question. The result of future fermentation experiments will, no doubt, decide this point, as also the probability of English tobacco cultivation being a commercial success. But it is, in the meantime, necessary to grow the plant under circumstances as closely allied as possible to those of its natural requirements, and to obtain a home grown leaf having, in the first place, an ash of a quality more nearly resembling the known composition of the ash from more naturally grown tobacco, than has been the case with the home-grown leaves examined up to the present time.

I have again to record my best thanks to Dr. Hodgkinson for enabling me to carry out the experiments.

DISCUSSION.

Mr. **Ruffle** was glad that this subject had been brought forward again, because, owing to the alterations in the Budget arrangements, the question of moisture in tobacco would have to be specially determined. While at work upon moisture in another subject, he had made a few experiments on tobacco also, in expectation of the question cropping up. He had not had an opportunity of dealing with pure leaves, but only with such as could be obtained from the shippers. He had found that by drying over dry calcium chloride the loss was not so great as in drying at 212° F. While fully admitting the importance of the results obtained as to the ash, it seemed to him that the character of the organic constituents must influence the character of the tobacco. That was a point which should be further investigated. He had found the results of drying at 212° F. to be sometimes 5 per cent. higher than in drying over calcium chloride. Might it not be that the cellulose, or whatever was the chief organic constituent, of leaves grown under certain conditions was more readily hydrated than when grown under other conditions? If so, such leaves would burn with more difficulty than those not so highly hydrated. The solution of this question might assist in determining the quality of tobacco leaves.

Mr. **Rideal** would like to know more of the early history of these tobaccos; whether they were of the same species, and also what was the nature of the manure used. Judging from the great variation of the author's results, the question of manure was important, and some further information upon that point would greatly help in forming a judgment upon the figures given. He would be glad to know, too, what Mr. Wingham considered to be a normal, or the best, ash. He had always understood that the presence of nitrates had an important influence on the burning of tobacco, but, judging from Mr. Wingham's remarks, it appeared to be otherwise. Chlorides also should affect the ash; and he would like to hear more on that point.

Mr. P. **Carmody** inquired whether the author could state what were the percentages of soda in the various samples, and whether they agreed with those of the samples previously treated.

Mr. **Wingham** replied that the percentages were slightly less, but very variable, being, in the samples before the meeting, 3·9, 2·8, 2·4, and 0·91 per cent.

Mr. **Carmody** explained that he had put the question, because it was well known that in ordinary ash the percentage of soda was always low—less than 1·2 per cent. It had been stated that these leaves were unfermented; and yet they were brown in colour. He had never yet known a brown leaf unfermented. He thought that the change of colour indicated that a change similar to fermentation had taken place. The sample No. 2 appeared to be different in character from the others. It was soft and flabby, and probably contained a good deal of water, and would yield a small amount of ash. As had been already suggested, much would depend on the character of the manure used. If the same manure had not been used on all the samples it would be difficult to compare them.

Mr. J. W. LEATHER pointed out that as yet there had been no opportunity of proving what English-grown tobacco would be like if fermented, the time not having yet arrived for last year's crop to undergo that process. In America, the crops harvested last summer would have been dried during the autumn, and would be fermented this spring. He had himself tried some English tobacco after drying, and had found it anything but nice; but he had no doubt that later on some smokeable English tobacco would be produced.

Mr. WINGHAM, in reply, said the point raised by Mr. Ruffle was of considerable importance at the present moment. It might interest chemists to know that by the new duty regulations 35 per cent. was the maximum moisture allowed in manufactured tobacco, and the authorised process for determination was drying at 212° F. What the difference might be if the determination was made in a vacuum over calcium chloride, he was not prepared to say. If the nicotine were present as a free base, it would probably be volatilised in the vapour of water by drying, and that might account for a slight increase in the moisture as determined at 212° F. It was possible, too, that the results shown by drying over calcium chloride were not correct; for instance, there might be a certain point at which the tobacco itself rather than the calcium chloride would absorb moisture. He did not think the higher percentage was due to hydrated cellulose. Referring to Dr. Rideal's questions, sample No. 8 was described as Kentucky tobacco, not heavily manured. The next sample was described as Kentucky tobacco also, but heavily manured with bat's guano. Little was known of the next sample, except that it was much mixed and had been stored in bulk for a considerable time. This storage would no doubt explain the percentage of nitrates. He did not think a "normal ash" could be defined, there being considerable variation in all kinds. No doubt the presence of nitrates had a decided influence on the combustibility of tobacco. Still their presence in quantity was not essential to a good tobacco; and if one took a good foreign leaf and examined it for nitrates, the chances were that one would find very small traces present. It might be expedient for manufacturers to introduce nitrates, but the effect was to render the tobacco quick-burning and hot. Chlorides also had a great influence on the burning qualities of the tobaccco. In the leaves grown by Lord Harris, chlorine was found far in excess of the amount required by the potash and soda. Consequently a considerable quantity combined with lime, producing calcium chloride. This fused in the burning of the leaf, clogging the carbonaceous matter, and preventing the oxidation of the last traces. If the chlorine was not in excess of the amount required by the soda and potash, probably little harm would be done. In burning the samples under consideration, the clogging effect had not been noticed, although 9 per cent. of chlorine was present. He had been much struck by the amount of soda found in Lord Harris's samples, but the ground on which they were grown had been manured with common salt. This would doubtless account for both the soda and the chlorine. The samples under notice were not manured with salt, and were grown on a chalky soil. It was erroneous to suppose that the brown colour of tobacco was an indication that fermentation had taken place. On the other hand, he had seen it stated that tobacco leaves could not be dried at all without becoming brown. That also was a mistake, since one of the dried samples under notice was green. The flabbiness of sample No. 9 was due to wear and tear. It had moreover been heavily moistened that day. If it were dry, it would be very crisp. He quite agreed with Dr. Leather's remarks about fermentation. It would be most unfair to compare these leaves with foreign tobaccos kept perhaps for two or three years. These leaves did not pretend to be thoroughly fermented. The process of fermentation involved many operations and much time. No doubt if these leaves were packed away under considerable pressure for a summer, as foreign leaves were, they would be much improved. He had tried some of this tobacco, especially No. 10 sample, which had been stored for some time, and whether in a pipe or as cigarettes, it was by no means the worst he had smoked. He thought, therefore, there was good hope for the future of English tobacco.

◆◆◆◆◆◆◆◆◆◆◆

Meeting held May 16, 1887.

MR. B. E. R. NEWLANDS IN THE CHAIR.

DISCUSSION ON MR. JOHN RUFFLE'S PAPER ON "A NEW METHOD OF ESTIMATING MOISTURE IN SUPERPHOSPHATES AND SIMILAR FERTILISERS."

THE CHAIRMAN considered the paper a most important contribution to the proceedings of the Society, and that the author's wide experience of the subject would ensure it respectful attention. The fact that the water in superphosphate was driven off under certain circumstances and not under others, was undoubtedly of importance in considering its mode of estimation. In making superphosphate, the mixture gave rise to a high temperature—considerably above that at which sulphate of lime would hydrate. Therefore, the water could not combine in the mixer or "den;" and before the temperature was sufficiently reduced for combination to occur, the whole mass became solid, and the water was thus locked up. If the superphosphate were pasted, the particles were brought closer together, and the sulphate of lime thus became hydrated, and the mass would set as plaster of Paris. In drying at 212° F., the water was given off at such a temperature that the sulphate could not catch it in its progress. But by Mr. Ruffle's process the water was taken out at a low temperature, and in its struggle to get out it saturated the sulphate to its full extent. Thus the result obtained in the latter case was less than that obtained by drying at 212° F. One of the tables in Mr. Ruffle's paper showed the composition of prepared superphosphates. In this table, "soluble oxide of iron," "soluble alumina," and soda were mentioned as existing as sulphates, and the amount of water of crystallisation assumed to exist in each salt was stated. If this were the case, it was obvious that at a comparatively low temperature efflorescence would occur, and the water of crystallisation would be given off, especially in vacuo. Therefore, the process would of necessity estimate the quantity of water existing in the form of these sulphates, and thus a slight error would arise.

Mr. F. NETTLEFOLD said that in analysing a certain boiler residue he had found $CaSO_4.H_2O$ to be present, and he further found that this body split up on heating it to 212° F. He would be glad to have Mr. Ruffle's opinion as to whether the presence of this hydrate would affect the estimation of water in superphosphate.

Mr. Crowder said the paper was well worthy the serious attention of the members, as coming from one whose work had given him an European fame. He had studied the figures given as far as time had permitted, and he could certainly say of some of the experiments that they confirmed results which had been obtained in his own laboratory. For instance, Mr. Ruffle had found that the soluble P_2O_5, and even the total P_2O_5, was affected by raising the temperature, and that "drying without rise of temperature did not affect the soluble nor the total P_2O_5;" and these results were quite in accordance with his own experience. Mr. Ruffle had said that a drying of from 5 to 7 hours was necessary in order to arrive at constant results. The decision of the percentage of moisture in superphosphates was a matter which had bothered him considerably. He had sometimes had to send out superphosphate, and questions had arisen as to its dampness. He usually reckoned about 15 to 15½ per cent. was the normal quantity in superphosphate, such as was made from Carolina phosphate. Of course the results obtained by drying in vacuo would be much more accurate; still, as the process took 24 hours, he was not certain that it would be much more advantageous than the rough-and-ready determination by means of the water bath, which could be done in two hours. With reference to Mr. Ruffle's difficulty in finding a good air pump, he might mention that he had found the Körting pump thoroughly satisfactory. He quite concurred with Mr. Ruffle's view that the phosphoric acid in these superphosphates was principally in the state of free phosphoric acid and not monocalcic phosphate. That question had in fact been settled some ten or twelve years ago by Professor Way. He did not think the lime was ever present in any quantity as acid-phosphate; it was always in the form of sulphate. He could not understand Mr. Ruffle's difficulty in determining the free sulphuric acid. If superphosphate were treated by absolute alcohol, any free sulphuric acid present would be detected. In conclusion, he would mention a curious and awkward experience which occurred to him some years ago in the manufacture of high-class superphosphates. On one occasion, in boiling the superphosphate down in an overshot pan, he suddenly found that the whole mass had solidified. The fires were immediately drawn and the pan cooled down, when it was found that the whole had solidified into a substance resembling green glass, which was insoluble in water, in acids and in alkalis. It was recovered by fusion into phosphoric acid. It was nearly free from lime, just as Mr. Ruffle had found the filtrate from the washing of the superphosphate. (Mr. Crowder exhibited a piece of this solid material, which resembled flint in appearance.)

Mr. Mumford desired to make a few remarks of a practical rather than a chemical character. Everybody who was concerned in the subject under discussion, would recognise the importance of having, in these days of keen competition, some universally-adopted method for the determination of moisture. He was not vain enough to suppose that people engaged in industrial chemistry would ever be able to dictate to scientific men with respect to their methods of determining the constituents of the articles they turned out; but he did think that in the case of such a constituent as moisture, some universal mode might be arrived at and adopted. In speaking of the advantages of testing for moisture by the rough-and-ready method of the water bath, Mr. Crowder had lost sight of the fact that, to save postage, very small samples were sometimes sent to the analyst, who was frequently required to make a complete analysis therefrom. The chemist might, therefore, be tempted to determine the moisture and the soluble phosphoric acid from the same identical portion of the sample. If he determined the moisture in the water bath at 212° F., he would cause a precipitation of the soluble P_2O_5, and the manufacturer would thus be mulcted not only in the excess of moisture shown by the one test as compared with the other, but also in the deficiency of the soluble phosphoric acid reverted by the method of determination. Mr. Ruffle's method, however, appeared to leave the soluble phosphoric acid as it was before the determination. He had himself some years ago endeavoured to dry on a practical scale a quantity of carefully prepared superphosphate. His first difficulty was to find a place having a constant temperature, and also large enough to permit of a test on a practical scale. At last he found a chamber over a boiler, where there was a constant temperature of 160° F. After carefully weighing, drying and sampling the superphosphate, the loss was determined. He then calculated the cost of producing such a superphosphate, taking into account the extra labour for manipulating it. On a sample being tested, however, he was astonished to find that even at the low temperature employed, a considerable loss of soluble phosphoric acid had occurred. He had of course not calculated on this, and had his estimate been acted on, a contract would have been made at great loss. This experience showed the necessity for great caution in such matters. He had thought that as moisture could be determined at 212° F., he was quite safe with a constant temperature of 160° F.; but the reverse was the case. He hoped that the outcome of this paper and discussion would be the adoption of some universally-recognised method of estimating moisture, and that manufacturers would thus be rid of the great difficulty which existed at present.

Mr. J. W. Leather said the last speaker had anticipated much of what he had intended to say, but from a different point of view. Was it really so important whether one determined the water at 100° C. or at no degrees. Of course the consequence of determining the water at 100° C. and at the atmospheric temperature would be to obtain different results; because, in the first case, one would drive off a proportion of the water of crystallisation of certain salts, and in the second case one would not. He had, however, never heard of an analyst determining the soluble phosphoric acid and the water of a superphosphate from the same portion. He would be glad to know what Mr. Ruffle meant by a vacuum. The term was of itself vague, and might mean any number of millimetres pressure. Would Mr. Ruffle say, too, whether he used a water or a mercury pump; and if the latter, how many millimetres of mercury the pressure in his receiver registered.

Mr. Bernard Dyer could corroborate what Mr. Ruffle and Mr. Crowder had said respecting free acid in superphosphate. He had often been asked to say how much free sulphuric acid was present, and had sometimes irritated manufacturers by saying there was none or only a trace. He had devised the alcohol method mentioned by Mr. Crowder for his own use, and thought he had hit upon something new; but found it had been in use previously. For ordinary purposes, however, good methylated spirit was as suitable as absolute alcohol. It had been known for some time that the text-book statements as to monocalcium phosphate were to some extent chimerical; and that the conventional methods of expressing their analyses were not scientifically accurate. Except as a point of scientific interest, however, that did not much matter, seeing that the soluble phosphoric acid was really the basis of the analyses. Referring to the table showing the moisture determinations of Sombrero and Carolina superphosphates by drying for five hours in the natural and beaten-up states, he would like to ask whether it was to be understood that the weights became constant at four or five hours, or whether Mr. Ruffle simply stopped the experiments then. In the case of the Sombrero sample, there was not a vast difference between the moisture in the natural state and the beaten-up moisture at the end of five hours. Possibly the mechanical difficulty had come in in these tests. When manure was beaten up to a paste, a dry pellicle formed upon it, in the same way as in the analogous case of drying a sample of sugar, so that the water might be mechanically kept from escaping. However, this question was quite apart from the main purpose of the paper. Mr. Ruffle's method and results were most interesting, and it would certainly seem that there might be an advantage in adopting his process; but a general agreement to do so would be necessary among chemists, or the conflicting figures of different analyses would be very annoying to the trade. It was undoubtedly, however, always more satisfactory when chemical analyses could be stated on an exact scientific basis. What was at present meant by "moisture" in most analyses was clearly not actual free water, but water which was driven off at 212° F. He would like to see further experiments, with the purpose of showing how far, for any one class of superphosphate, the difference between the absolute moisture and the conventional loss at 212° might be constant. Probably some analysts would adopt this new method at once, and others only by degrees; and in face of this possibility, misunderstanding might perhaps be avoided by stating on the analyses: "Moisture (loss at 212°)," or "Moisture (loss *in vacuo*)."

In reply, Mr. Ruffle said with respect to the question as to the soluble alkalis shown in Table 5 being sulphates, he thought he had succeeded in showing them to be not sulphates but phosphates. As there was not sufficient sulphuric acid found in the filtrate to combine with the iron, magnesia, etc., as sulphates, they must have been phosphates. He could quite understand Mr. Crowder's and Mr. Dyer's remarks about the constancy at 212°. It was always difficult to get out of an old groove: but he would ask makers to bear in mind that the question "What amount of moisture will you guarantee?" had already come across the water. Competition was now very keen; and if one man would not guarantee the correct moisture, another would. From the chemical point of view the old method would be beaten, and the water bath would have to be abandoned for something else. If chemists were asked to determine moisture they should do so to the full extent of their ability. So long as they knew nothing better than the determination at 212°, they were right in using it. But if they had now another method, and found that the result obtained at 212° F. was not absolute moisture, they should cease to call it so. The question of what was true moisture in superphosphate still remained. Buyers sometimes would refuse to accept a parcel on account of its being "too wet." The seller would then send a sample to a chemist; but how was he to determine whether it was too wet by reason of an excess of water having been put in, or whether the manure was merely out of condition from other causes. The manufacturer had no doubt intended to be correct, and the right proportion of O. V. had been used; but the men had perhaps run in too much water with the O.V. If the analyst wanted to find out whether the manure had been correctly mixed, how could he do so by testing at 212°? If, however, he carefully calculated it out by the calcium method, he probably would be able to tell. With all respect to Mr. Crowder, he could not admit the correctness of the method employed by him for estimating the amount of free sulphuric acid. One had in these manures a more or less concentrated solution of phosphoric acid, lime and sulphuric acid. Some of that lime might be combined with the phosphoric acid—at any rate, one could not prove that it was not. To that solution of water, phosphoric acid, lime and sulphuric acid, alcohol was added. A precipitate of sulphate of lime was thus got. But how could one prove that that sulphate existed before the alcohol was put in? Might it not have been formed by the sulphuric acid combining with the lime after the addition of the alcohol, and thus producing an insoluble sulphate of lime? If so, the really free sulphuric acid would be put too low. He was glad to learn that the results worked out by him as to the effect of temperature had been confirmed practically. As to whether a correct determination of water was necessary or not, he thought it was. Such determinations were more and more appreciated technically, and would, he thought, be in time generally required. In reply to the question as to the vacuum employed, he had taken an ordinary Tate's air pump, and had worked it until he could produce no further vacuum. He had attached a mercury gauge, but had not measured off the exact number of millimetres registered. The difference between the two limbs of the gauge was about half-an-inch, and on leaving the pump for 24 hours he found that the mercury in the higher limb had not gone up $\frac{1}{8}$in. That was practically the utmost limit that could be obtained, and that was what he had adopted. The figures in Table 4, queried by Mr. Dyer, were not constant. They simply showed the loss obtained in so many hours. As stated in the paper, these samples were taken from large heaps, and were dried at 212° F., both in the natural and in the beaten-up state; and these figures had been given in order to show that the results obtained from actual samples of ordinary superphosphates made on a large scale agreed with those which he had got from samples of known composition, and that they might therefore be accepted for guidance practically. It had been suggested that there might be a constant margin between the absolute moisture of a superphosphate and that determined at 212° F. He did not think so. If the phosphate employed was always of the same quality, and if the same quantity and strength of acid was always used, the margin might be constant. But inasmuch as phosphates varied in quality, they would carry different quantities of acid. And, again, whereas one maker would mix with 105 acid, because he could not get a stronger, another would use 120 acid, because he had it, and it was convenient. But the analyst would know nothing of these differences of preparation. Sooner or later one method or the other must be adopted, and he did not doubt that it would be that one which was most correct.

◆◆◆

NOTES OF A RECENT VISIT TO SOME OF THE PETROLEUM PRODUCING TERRITORIES OF THE UNITED STATES AND CANADA.

BY BOVERTON REDWOOD, F.I.C., F.C.S.

A large proportion of the crude petroleum produced in the United States is still obtained in what is known as the Bradford district. This oil territory, lying partly in central and northern McKean County, Pennsylvania, and partly in southern Cattaraugus County, New York, has an area of 133 square miles, 121 square miles of which are included in the Bradford field proper. The development of this territory dates from the year 1874, when the first successful well was drilled, and four years later—viz., in December, 1878—the average daily production of the Bradford district was no less than 23,700 barrels (of 42 American gallons) or about four sevenths of the total daily production of the State of Pennsylvania. Two years later still the Bradford district supplied 63,000 barrels per day, out of a total production of 72,215 barrels per day. During recent years there has been a steady decline in the production of this prolific territory, notwithstanding the efforts made to maintain the output. Up to January, 1885, the Bradford district was estimated to have yielded 109,000,000 barrels, an average of about 820,000 barrels per square mile. The total productions of the oil regions of Pennsylvania and southern New York up to the same date has been given on the authority of Stowell's statistics as 260,990,435 barrels. In December last there were in the Bradford district, according to Stowell, 13,505 old wells with an aggregate daily production of 17,887 barrels (1⅓ barrel per well), and 16 new wells with an aggregate daily production of 100 barrels (6 barrels per well).

During the past year the attention of petroleum producers has been chiefly centred on the Washington field in Washington County, Pa. In December, 1884, a well was drilled on the Gantz farm, in this field, by the Citizens' Fuel Company, with the object of obtaining natural gas for use as fuel. At a depth of 2200 feet, oil, and not gas, was obtained, and this discovery at once led to the drilling of other wells. In August, 1885, a flowing well known as the Gordon well was completed, and in the following year several other exceedingly productive flowing wells were drilled, one of the number, the Thayer well, yielding 2000 barrels per day. The production of the Washington field reached its maximum of 16,000 barrels per day in August last, and had declined to 8000 barrels per day at the end of the year. Stowell gives the aggregate daily production of the Washington field in December last as 7720 barrels from 180 old wells (43 barrels per well), and 2560 barrels from 33 new wells (71 barrels per well).

The daily production of the various oil-fields of Pennsylvania, New York and Ohio (expressed in barrels of 42 American gallons) on the 1st January, 1886, and 1st January, 1887, was as follows :—

	1887. Jan. 1.	1886. Jan. 1.
Allegheny	5,800	6,400
Bradford	24,600	29,000
Kane	1,500	80
Cherry Grove	210	400
Cooper	450	750
Balltown	650	1,200
Grand Valley	2,100	*
Cogley	1,600	5,200
Tarkill	1,750	*
Baldridge and Thorn Creek	2,000	1,400
Red Valley	800	*
Pontins	2,800	*
Oil Creek, Tidioute, Clarion, Armstrong, Warren, etc.	11,500	11,500
Washington	8,500	250
Shonstoun	3,300	60
Macksburg	1,300	1,900
Totals	71,390	63,140

The yearly production of crude petroleum in Pennsylvania and the contiguous States from the beginning of the year 1859 to the end of last year is given in the following table in barrels of 42 American gallons :—

1859	5,000	1873	7,878,629
1860	500,000	1874	10,950,730
1861	2,113,000	1875	8,787,506
1862	3,056,000	1876	9,175,906
1863	2,611,000	1877	13,490,171
1864	2,116,000	1878	15,165,462
1865	2,497,000	1879	19,741,661
1866	3,597,000	1880	26,562,000
1867	3,347,000	1881	28,447,115
1868	3,583,000	1882	31,051,165
1869	4,210,720	1883	24,090,000
1870	5,673,195	1884	23,520,817
1871	5,715,900	1885	21,600,651
1872	6,531,675	1886	25,816,000

During the past year the consumption of United States crude petroleum, produced in the districts referred to, has been as follows :—

	Barrels.	Barrels.
Total deliveries from the oil regions	26,803,400	
Deduct total exports	16,431,300	
Total home consumption		10,372,100
Total exports from the United States	16,431,300	
Add decrease in European Stocks †	150,000	
Total foreign consumption		16,581,300
Average daily home consumption	28,400	
Average daily foreign consumption	45,100	
		73,800

The consumption of crude petroleum for the year 1886 thus exceeded the production by more than 2000 barrels per day, the deficiency being supplied from the stocks. These stocks, held by the storage companies, at the end of the year 1886 amounted to 34,156,605 barrels. The average price of crude petroleum in the United States during 1886 was 70⅝ cents. per barrel.

The wells in the Washington field being several hundred feet deeper than those in the older fields, and being constructed in accordance with the most modern principles of drilling, may be taken as illustrating to the fullest extent the development which has taken place in this important branch of mechanics, and it will therefore be interesting to consider the details of construction of these wells.

The derrick employed does not differ materially from those erected in the older fields, but is of somewhat greater height and strength, the greater depth of the wells necessitating the use of longer and heavier drilling tools. The structure is usually about 80ft. in height by about 20ft. square at the base, and is strongly braced by diagonal stays. The stems of the drilling tools are 4in. in diameter, and the "string of tools," as it is called, consisting as usual of "bit," "auger stem," "jars," "sinker-bar," and "rope-socket," is frequently from 65ft. to 70ft. in length, and weighs from 3000lb. to 3500lb. The well is commenced by inserting a wooden "conductor," or iron "drive pipe," which extends from the surface, through the soft ground, to the top of the first stratum of rock. The drilling is then commenced, and it is usual in the Washington field to use for the upper part of the well a drill 13in. in diameter. As the drilling proceeds the well is "cased" to support the walls, and to exclude water. The casing employed for the upper part of a well drilled with a 13in. bit consists of strong iron tubing, 10in. in internal diameter, carefully screwed together in lengths of 17½ft. to 20ft. When this 10in. casing cannot be lowered any further the drilling is continued with a smaller bit, and casing of a corresponding diameter is inserted. A further reduction of size is usually made before the well is completed. Thus a well which I visited was commenced with from 16ft. to 18ft. of wooden conductor, and contained, on being finished, 682ft. of 10in. casing, 1060ft. of 7⅝in. casing, and 1750ft. of 5⅝in. casing. Each "string" of casing extends downwards from the mouth of the well, and

---

* Not specified January 1, 1886.

† The statements of stocks at foreign ports other than European had not been received when this table was compiled.

the upper part of the well is therefore lined with three thicknesses of iron, the casing of such a well thus requiring nearly three-quarters of a mile of iron tubing.

The average depth of the wells in the Washington field is 2400ft., but at the time of my visit there was one well producing which was of the depth of 2595ft.

Only the most experienced drillers are able successfully to cope with the difficulties attendant upon drilling to such a depth as 2400ft., and even workmen of the highest skill occasionally fail, for there are wells in this field which have been abandoned with three sets of tools in the bore, after fruitless exertions in "fishing," as the operation of raising or attempting to raise the lost tools is termed. The chief difficulty arises from the caving of the rock as the drilling proceeds and before the casing is inserted. The average time occupied in the drilling of a well in the Washington field is about four months, and the cost of each well is as much as £1600. In the Bradford field the cost of a well was usually estimated at from £500 to £600. Drilling is paid for in the Washington field at the rate of 7s. to 8s. per foot, as compared with 1s. 10d. to 2s. 5d. in the Bradford field. At this rate of payment, the well-owner furnishes the derrick (which costs about £100), the boiler, of 25 h.p. (costing about £100), the engine, of 20 h.p. (costing about £40), and the connections (costing about £20), while the drilling contractor uses his own cable and tools, and finds coal and labour. Occasionally the contractor provides the engine, boiler, and connections, and then is paid at a higher rate for each foot drilled. The gang consists of two drillers (who receive from the contractor 16s. each per day) and two tool dressers (who are paid 14s. each per day). The drillers and tool dressers work in pairs as a day and a night shift, so that the work proceeds continuously. The well owner is usually the lessee, for oil-producing purposes only, of the land. Oil leases in the Washington field are as a rule for five years, or as much longer as oil or gas is produced in paying quantities, and almost invariably it is provided by covenant that the lessee is to commence development within a year, or in some cases two years, or in lieu thereof is to pay a stipulated rent per acre. The landowner, or farmer, retains the right to use the land for agricultural purposes, the oil-lessee being entitled only to so much of the surface as he may require for the purpose of petroleum production, and for ingress and egress. The terms of such a lease frequently are that the lessor receives a cash payment of £20 per acre (if the district has already produced oil) and one-eighth of the oil produced (in kind).

The wells are invariably torpedoed on the completion of the drilling, with the object of shattering the oil-bearing rock, and increasing the flow of oil. The torpedo employed consists of a shell of tin-plate filled with nitroglycerine. In the Washington field it is a common practice to torpedo a well several times, with increasing quantities of the explosive, the final charge amounting to 80 quarts, or in some cases as much as 100 quarts. The nitroglycerine is manufactured in the neighbourhood in a manner which, it may be confidently asserted, would not receive the approval of Her Majesty's Inspectors of Explosives, and is conveyed to the well in tin cans, holding from six to eight quarts, placed in padded compartments in a spring waggon. The torpedo cases or shells are usually about 10ft. in length by 3½in. in diameter. Such a case holds 20 quarts, and accordingly as many as four are employed when a charge of 80 quarts is to be exploded, the cases being successively lowered into the well as they are filled with nitroglycerine. The torpedo was formerly provided with a percussion firing head, and was exploded by dropping a "go-devil" or cast-iron weight into the well, but owing to the increased size of the bore of the wells this method of causing the explosion has been superseded by the use of a "go-devil squib," which is practically a miniature of the torpedo, provided with a percussion firing head, and suspended in the well in proximity to the torpedo proper by means of a cord on which a perforated leaden weight runs. The weight being dropped is guided by the cord to the head of the squib, and the explosion of the small torpedo being thus effected, that of the large torpedo immediately follows. The torpedo is generally fired under about 50ft. or more of water. The distance from the surface of the ground being so great, little or no sound is heard when the explosion occurs, but a slight tremor of the ground is usually felt, and the water and oil in the well are projected upwards to a great height.

Nearly all the wells in the Washington field are flowing wells, the flow usually being continuous. The maximum regular yield per well is probably from 600 barrels to 700 barrels (20,160 to 23,520 imperial gallons) per diem, but one well in this field is estimated to have given 3600 barrels (121,000 imperial gallons) per 24 hours for about a week after it was completed. In consequence of the great expense of drilling in the Washington field, no well which yields less than 100 barrels (3360 imperial gallons) per day is considered to pay, at the present price of crude oil.

Most of the crude petroleum produced in the Washington field is what is known as amber oil. Prior to the development of this field, such oil had never been found in large quantity, and petroleum experts accordingly predicted that the Washington field would not be found to be very productive, but subsequent experience demonstrated the small value which such predictions in matters relating to petroleum production possess. I have on the table an interesting representative series of samples of crude petroleum from the Washington field. The character of these samples is indicated in the following table :—

No.	Name of Well.	Sp. Gr.	Colour.
1	Mulholland, McKeevor & Co.'s Lead Works Lot	0·790	Yellow
2	Cameron, 1	0·777	,,
3	The Caldwell and Marsh	0·798	Amber
4	Union Oil Co., McGovern	0·798	Yellow
5	The Weaver, No. 1	0·800	Amber

The odour of all the samples is moderately strong, but not disagreeable.

The specific gravity and colour of a representative series of samples from the older fields placed on the table for comparison are as under :—

Name of Field.	Sp. Gr.	Colour.
Bradford	0·810	Reddish brown
,,	0·819	,,

Name of Field.	Sp. Gr.	Colour.
Parker (Clarion)	0·797	Reddish brown
,, (Karns City)	0·789	,,
Thorn Creek	0·802	,,
Stoneham	0·802	Dark amber
Macksburg	0·829	Reddish brown

The crude petroleum found in the Washington field contains a considerable quantity of solid hydrocarbons, which to some extent crystallise out in cold weather. A sample of the paraffin which thus separates is exhibited.

I have also on the table a number of specimens of the oil sands from the same field, of which the following is a description:—

1. "Manifold" sand. Small red and grey particles in equal proportions.
2. "Gantz" sand. Black, grey, and white particles in equal proportions.
3. "Fifty foot" sand. Of a pale brown colour.
4. "Stray" sand. For the most part of a greyish colour, but with a few reddish-coloured particles intermixed.
5. "Gordon" sand. Similar to the "Gantz" sand, but of finer grain.

The following is the record of a well on the Israel Weirich farm in the Washington field, showing the depths from the surface and the thicknesses of the oil sands met with:—

	Depth.	Thickness.
Top of "Big" or "Mountain" sand	1,433ft.	240ft.
,, "Gantz" sand	2,080	30
,, "Fifty-foot" sand	2,187	50
,, "Stray" sand	2,379	24
,, "Gordon" sand	2,404	35

The decline in the production of the Bradford field has given rise to some apprehensions of an approaching scarcity in the supply of crude petroleum in the United States, but although there are no indications which warrant the belief that another equally prolific territory will be discovered, it is certain that petroleum exists in very considerable quantities in many States of the Union, besides Pennsylvania and New York. The petroleum of Ohio has already been referred to. The oil found in the Lima field in this State is described by Professor Orton, State Geologist of Ohio, as a "black, sulphuretted and rather heavy" oil. The specific gravity appears to range from 0·818 to 0·843. Considerable difficulty has been experienced in producing from this petroleum an illuminating oil of good quality. Petroleum is also obtainable in large quantities in West Virginia, Kentucky, and Tennessee. It is also found in Alabama, Florida, Michigan, Illinois, Indiana, Missouri, Kansas, Louisiana, Nebraska, Montana, Wyoming, Dakota, Colorado, New Mexico, and California.

The Governor of Wyoming, in a report to the Secretary of the Interior, dated 1885, states that the most extensive oil basins of the territory lie east of the Wind River, and north of the Rattlesnake range of mountains, the principal deposits being apparently located in the Fort Washakie, Lander, Shoshone, Beaver Creek, Big Horn, Rattlesnake, Seminole and Laramie ranges. A trial well drilled in the Shoshone basin to a depth of 72ft., is stated to have yielded at the beginning of the year 1885, 40 barrels (of 42 American gallons) of oil per 24 hours.

I had occasion some time ago to examine a number of samples of crude petroleum from the Shoshone basin in Wyoming, and found them to possess the following characters:—

No of Sample.	Sp. Gr.	Colour.	Odour.
1	0·912	Very dark brown	Strong and disagreeable
2	0.912	,,	,,
3	0.912	,,	,,
4	0·910	,,	,,
5	0·911	Brownish black	Slight and disagreeable
6	0·911	Very dark brown	Strong and disagreeable
7	0·915	Brownish black	Slight and disagreeable

The yield of commercial products from Samples Nos. 6 and 7, portions of which are on the table, I found to be as follows:—

No.	Naphtha.	Kerosene.	Intermediate and Lubricating Oils.	
6	2·5	27·5	52·5	per cent.
7	none	10·0	72·5	,,

Considerable attention has been given to the development of the petroleum resources of California, the local demand being, to some extent, supplied with refined oil, manufactured in the State from native crude petroleum, and I was glad to have an opportunity last autumn of visiting the principal producing territory, situated in Pico Cañon, near the city of Newhall, in Los Angeles County. The existence of oil in this locality was discovered by Andreas Pico prior to 1857, but the development may be said to date from 1869, when the Pico well was drilled. It was not, however, till 1875 that drilling was actively commenced. Petroleum is also obtained in Ventura County, California, near Santa Paula, where drilling was commenced in 1874; from a small group of wells in the Santa Cruz mountains; from Puente, east of Los Angeles, where drilling first took place about 18 months ago; and in still smaller quantities from several other localities in the State of California. I was informed that the oil produced in the Ventura territory, which is from 35 to 40 miles west of Newhall, is conveyed by pipe to the seaboard, and thence in tanks by steamship to San Francisco, where it is refined. I was not able to ascertain the production of this territory, but I presume that it is very small, and I was told in San Francisco that the oil being refined there at the time of my visit all came from Pico Cañon. The quantity of crude oil found in the Santa Cruz mountains is as yet very limited, the production not exceeding from 10 to 15 barrels per day. The oil is stated to have a specific gravity of 40° B. (0·830), and to contain a good deal of paraffin.

In the ravine at Newhall we found a little colony, where Mr. Mentry, the manager at the wells, and the workmen reside. The wells number 16 in all, and are from 700 to 2000ft. in depth. The petroleum is found in the tertiary formation in sandstone, but there do not appear to be any well-defined oil-bearing strata, the oil being found in greater or less quantity at almost all depths. The oil-belt at present defined has a length of about two miles, and is about a quarter of a mile in width. The individual yield of the wells ranges from five to seven barrels up to 40 barrels per day, and the aggregate production is stated to be 500 barrels per day. The oldest of the wells was drilled about 10 years ago, but has been deepened since, and all the wells are still yielding. Only one of the wells is classed as a flowing well, but we were informed that all would flow if the gas pressure were allowed to accumulate. The flowing well was drilled about four or five years ago, and was at first pumped for about five months, but it has since flowed at intervals of about 20 minutes, and now yields 40 barrels per day. We saw this well flowing, and observed that the discharge took place with considerable force for the space of nearly five minutes. Each well is connected with a cylindrical iron vessel, through which the oil passes, and where the gas which escapes with the oil is collected and used as fuel, the steam boilers being heated exclusively with this natural gas. All the wells, with the exception referred to, are pumped once a-day, a 1¾in. pump with 24in. stroke, worked in the usual manner through the medium of the rocking beam, being employed. Mr. Mentry stated that the oil did not, as a rule, vary greatly in quality, but one well (No. 13) yielded an oil containing so large a proportion of solid hydrocarbons, that difficulty was sometimes experienced from the clogging of the pump tubing with paraffin. I obtained an average sample of the crude petroleum, to which I shall have occasion to refer later. The oil passes from the wells to a receiving tank holding 25,000 barrels, and is thence conveyed, partly by gravitation and partly by pumping, through a 2in. pipe to Newhall, where it is run into tank waggons on the railway for conveyance to San Francisco. The whole of the Pico Cañon oil-field is now under the control of the Pacific Coast Oil Company, though there are still some separate subsidiary interests. The Company have not drilled any wells recently, but they contemplate making further developments at an early date. The derricks used are 72ft. in height, and the wells are usually commenced with a bore of 10 to 12in., but this is necessarily reduced, on account of "caving," as the drilling proceeds, and although efforts are made to complete the well with a diameter of not less than 5⅝in., some of the wells are at the bottom only 3¾in. in diameter. What is known as a "stove-pipe" casing of sheet iron is generally used instead of a wooden conductor in starting the well, and this casing is commonly from 10 to 20ft. in length. The wells are cased throughout, but are frequently not provided with any arrangement for shutting off the water, which is met with at a depth ranging from 100 to 300ft. The drilling is exclusively conducted with cable tools, and the wells are never torpedoed. It takes from four to five months to drill to a depth of 1500ft. under favourable circumstances in the Pico Cañon. Before drilling was commenced in this locality attempts were made to obtain petroleum by driving tunnels of 20 or 30ft. in length into the hill side, and our attention was called to one of these tunnels, from which, at one time, about half a barrel of oil per day was obtained, and from which we saw a small quantity of petroleum still flowing.

While at San Francisco we visited the refinery of the Pacific Coast Oil Company, situated at Alameda Point, 11 miles from San Francisco. There is a small refinery at Newhall where a portion of the crude petroleum from Pico Cañon is distilled, but the refinery at Alameda is the only one in California where finished kerosene is made. The present capacity of this refinery is about 500 barrels of crude oil per day, but the works are situated in an enclosure of considerable size, and it would be easy to increase the plant. At the present time, however, only the oil produced in the Pico Cañon is being refined, much of the oil found in California being a black heavy oil, not available as a source of kerosene, and the existing arrangements are amply sufficient for dealing with this. The crude oil, which has a specific gravity of 39° to 40° B., is stated to yield about 44 per cent. of kerosene of good burning quality, having a specific gravity of 44° B., and a fire-test of 110° F., but as much as 65 per cent. of 110° test oil can, it is said, be obtained. Of what is known as water white oil, of a nominal fire-test of 150°, the crude petroleum is stated to yield about 20 per cent. The yield of naphtha is given as about 15 per cent.

I have examined and subjected to fractional distillation the sample of crude petroleum which I brought from Pico Cañon. The petroleum has a specific gravity of 0·844. It is dark brown in colour, and has a rather pleasant odour. It yields, by the method of distillation I am accustomed to adopt—

Naphtha	15 per cent.
Kerosene	45 ,,
Intermediate and lubricating oils	32 ,,

Before leaving San Francisco I had a lengthened conversation on the subject of Californian petroleum with Mr. Henry G. Hanks, formerly State Mineralogist. Mr. Hanks, whose fourth annual report to the Californian State Mining Bureau contains a good deal of valuable information concerning the petroleum industry of the State, has been good enough to furnish me with the following interesting specimens—

1. Asphaltum in sand, Santa Cruz.
2. Crude bréa-asphaltum, Los Angeles.
3. Crude maltha or tar, Sargent's Ranch, Santa Clara County.
4. Crude bréa-asphaltum, Sargent's Ranch, Santa Clara County.
5. Refined asphaltum—artificial, Sargent's Ranch, Santa Clara County.
6. Asphaltum refined by natural process, Sargent's Ranch, Santa Clara County.
7. Crude bréa-asphaltum, Coral de Piedra, San Louis Obispo County.
8. Maltha, so-called "tar," San Louis Obispo County.
9. Asphaltum, San Louis Obispo County.
10. Asphaltum, ,, ,,
11. Asphaltum, ,, ,,
12. Bituminous sandstone, San Louis Obispo County.
13. Crude petroleum, Pico Cañon, Los Angeles County.
14. Maltha, first yield of wells at Petrolia, Los Angeles County.
15. Crude petroleum, Tunitas Creek, San Mateo County.

Sample No. 1 consists of 19·8 per cent. of asphalt and 80·2 per cent. of sand. Sample No. 2 is from La Bréa Rancho, so named from the Spanish word "bréa," signifying pitch, which lies about six miles west from the city of Los Angeles. Mr. Hanks states that the deposits here, which cover a large area, consist mainly of bitumen and maltha, the latter occuring in the form of pools or wells. As at Carpentaria, in Santa Barbara County, the tar-like substance flowing from the numerous apertures becomes mixed with such quantities of mineral and vegetable matter, that the whole mass has to be melted, and the impurities separated from the asphalt to fit the latter for market. To effect this the material is melted in iron kettles, and the impurities floating on the surface being skimmed off, additional material is thrown in until the kettle is nearly filled with comparatively pure asphaltum, when the charge is poured out into trenches dug in the earth. The pigs on being broken up after cooling constitute commercial asphaltum. From this locality the Catholic fathers obtained asphaltum for roofing the missions and other buildings put up at Los Angeles, San Gabriel, and elsewhere in the vicinity. Samples Nos. 3, 4, 5, and 6 are from Sargent's Ranch, a few miles south of the town of Gilroy, in Santa Clara County. Petroleum is here found exuding from the sandstone at several points along Tar Creek. Upon exposure the liquid becomes converted into maltha and asphaltum, considerable quantities of which have accumulated. The petroleum, according to Mr. Hanks, exudes from the hill-side in a thin tarry stream, with a motion that is almost imperceptible when the weather is cool, but which increases with the temperature of the atmosphere. Much of the asphalt presents a vitreous appearance, resembling that of the best quality from Trinidad. Some of the pools formed are as much as 10ft. in diameter, and of unknown depth. In cool weather the surface is sufficiently firm to admit of walking over it, but on warm days the surface is too yielding to bear the weight of a man. When dug up and thrown into heaps the hard asphaltum at common temperatures gradually softens and spreads out into a thin sheet. At the point where the first deposits are met with going up the creek, works have been erected for purifying the bréa by fusion and straining. Some 20 or 30 tons of asphaltum have been obtained here. Half-a-mile up the creek other large beds of asphaltum exist, which are fed from springs on the bank of the stream, and about 30ft. above its bed. From these deposits seventy-five car loads of asphaltum have been sent to San Francisco. A mile and a half further up the creek a third, and by far the largest, bed of asphaltum in this series is met with, the deposits here covering several acres. The land at this place spreads out into a plateau, and the supplying springs, many in number, are located on the neighbouring hillside. From the surface of the tarry pools bubbles of gas escape, similar to those observed at the Mud Lakes on the Colorado desert, and remains of birds and small animals which have become ensnared in the tar are to be seen. From this locality 200 car loads of asphaltum have been sent to market.

According to Mr. Hanks, the following comprise the more notable localities of asphaltum and maltha in the State :—Santa Ynez and Kayamos Valleys; near Mission, San Buenaventura; at the Goleta Landing, seven miles west of the town of Santa Barbara; on the Laguna Todos Santos and Los Alamos Ranchos; in the vicinity of Dos Pueblos, and near Carpenteria, in Santa Barbara County; at the oil wells near Sulphur Mountain, Ventura County; Rancho La Bréa, Los Angeles County; on the Corral de Piedra, San Louis Obispo County; about Buena Vista Lake, Kern County; and on Sargent's Ranch, Santa Clara County.

The quantity of asphaltum consumed in the State in 1884 was about 3500 tons per annum, the annual receipts at San Francisco reaching 2500 tons. The principal supplies come from Santa Barbara County, and the product from this locality being preferred, commands a price from 20 to 30 per cent. higher than that obtained for asphaltum from other deposits in the State. The wholesale price of asphaltum in 1884 was 13dols. per ton for the best, and from 9dols. to 11dols. per ton for poorer qualities. The cost of extraction ranges from 2dols. to 3dols. per ton, according to the hardness of the material, it being necessary occasionally to resort to blasting.

The material is largely used in California, as elsewhere, for street pavements, cellar floors, and roofing. It has also been used in the construction of water pipes, the process consisting in coiling on a mandril the cloth known as burlap, previously soaked in melted asphaltum, glazing the interior of the pipe thus formed by pouring in melted asphaltum, and finally rolling the pipes on a table covered with coke dust, whereby they acquire a smooth, dry, and hard surface. The pipe thus manufactured is light, durable, and cheap, the price, inclusive of couplings, being a sum per foot equal to the diameter of the pipe in inches, multiplied by 10 cents. Thus, 2in. pipe costs 20 cents per foot, 4in. pipe 40 cents, etc. Such pipe is said to have been made to stand an internal pressure of 500lb. per square inch.

Mr. Hanks states that the Californian petroleum-bearing rocks belong to the tertiary age, as shown by the fossils. At Pico Cañon the sand rocks are stratified with much regularity, and are interstratified with plates or seams of gypsum. There also occur here a black shale and a coarse conglomerate.

According to Professor S. F. Peckham, who has devoted much attention to the subject, the maltha of Southern California passes by insensible gradations from a material scarcely to be distinguished from heavy petroleum to solid asphalt, and varies in specific gravity from 0·9906 to 1·10; the heavier description still remaining plastic, like mortar.

When I visited Canada in 1877—78, the refining of petroleum was principally conducted in the city of London, Ontario. At the present time Petrolia, Ontario, is the chief seat of the industry, and it was accordingly to this city that we made our way. Here we were treated with the greatest kindness and hospitality by Mr. John D. Noble, vice-president of the Petrolia Crude Oil and Tanking Co., and his brother, Mr. R. D'Oyley Noble, and were enabled in the short time at our disposal to visit typical portions of the producing territory, and some of the principal refineries.

The development of the Canadian petroleum industry may be said to date from 1857, when a well dug for water was found to yield a considerable quantity of petroleum, but long previously, indeed from the time of the earliest settlements in the county of Lamberton, in the western part of the province of Ontario, petroleum was known to exist in Canada. In 1862 productive flowing wells were drilled at Oil Springs, but these wells, which were comparatively shallow, quickly became exhausted, and the territory was deserted on the discovery in 1865 of oil at Petrolia, seven miles to the northward, and about 16 miles south-west of the outlet of Lake Huron. Recently the Oil Springs wells have been drilled deeper, and are now producing 10,000 to 12,000 barrels (of 42 American gallons) per month. Petroleum has also been found at Bothwell, 35 miles from Oil Springs, but this district has ceased to yield. Quite recently a new territory has been discovered at Euphemia, 17 miles from Bothwell, where, at the time of our visit, there were four wells producing collectively 70 barrels per day. This territory is by some regarded as part of the Bothwell field.

The present producing oil-belt extends from Petrolia in a north-westerly direction, to the township of Sarnia, and in a south-easterly direction to Oil Springs, but in the latter direction there is a break of about four and a quarter miles, commencing at a point about two miles from Petrolia. At Oil Springs there appears to be a pool about two miles square. The extension of the belt then continues in the same direction, with another break of about nine miles, to the new oil field of Euphemia, the average width of the oil-belt being about two miles. In all, about 15,000 wells are believed to have been drilled in the Canadian oil-fields, and of these about 2500 are now producing, the average yield being about three-quarters of a barrel per well per day. The aggregate production is probably about 700,000 barrels per annum, the greater part of which is obtained in the Petrolia district, and the stocks were at the time of our visit stated to amount to from 400,000 to 450,000 barrels.

In the Canadian oil-fields the drilling contractor usually employs his own derrick, engine, boiler, and tools, furnishes wood and water, cases the well, and fixes the pump; the well owner providing the casing and pump, and subsequently erecting the permanent derrick. The wells in the Oil Springs field were formerly from 200ft. to 300ft. in depth, but the oil stratum then worked became waterlogged, and the wells are now sunk to a depth of about 375ft., and are cased to a depth of about 275ft. to shut off the water. The contract price for drilling a 4⅝in. hole to a depth of about 375ft. under the conditions mentioned is 150dols. (£30), and the time occupied in drilling is usually about a week when the work is continued night and day. The wells in the Petrolia field have a depth of 480ft., the contract price, including the cost of 100ft. of wooden conductor, being 175dols. (£35), and the time occupied in drilling being from six to twelve days. Pole tools are used in drilling, the poles being of white ash, 37ft. in length. The derrick is about 48ft. in height. An auger some 4ft. in length, and about a foot in diameter, is used to bore through the earth to the bed rock, the auger being rotated by horse power. The drilling tools commonly consist of a bit, 2½ft. in length by 4⅝in. in diameter, weighing about 60lb.; a sinker bar, into which the bit is screwed, 30ft. in length by 3in. in diameter, weighing about 1040lb.; and the jars, inserted between the sinker bar and the poles, about 6ft. in length, and weighing 150lb. The tools are suspended by a chain, which passes three times round the end of the walking beam and thence to the windlass, with ratchet wheel, fixed on the walking beam, by means of which the tools are gradually lowered as the drilling proceeds. The cable is thus only employed in raising the tools from the well, and lowering them into it. The sand pump or bailer is frequently as much as 37ft. in length, and is about 4in. in diameter. The casing (4⅝in. diameter) costs about 45 cents (1s. 10½d.) per foot, and the 1¼in. pump, with piping, costs from 65dols. (£13) to 85dols. (£17), according to the length of pipe required. An ordinary square-frame derrick costs, with mud-sill, from 22dols. (£4 8s.) to 27dols. (£5 8s.), and the walking beam about 8dols. (£1 12s.). In many cases, however, a three-pole derrick, which can be erected at an expense of about 10dols. (£2), is employed. A 100-barrel wooden tank costs, erected, 50dols. (£10.) The wells are torpedoed on completion with from 8 to 10 quarts of nitroglycerine, at a cost of 4dols. (16s.) per quart. The torpedoes employed in the Canadian oil-field are much smaller than those used for a similar purpose in the United States, the tin shell being only 6ft. in length by 3in. in diameter. We were enabled to witness the operation of torpedoing a well, and the following particulars, based on notes taken at the time, may be of interest:—The torpedo case, which was furnished with a tube or "anchor" at the lower end, 8ft. in length, was placed in the mouth of the well and suspended so that its upper end was level with the surface of the ground. Eight quarts of nitroglycerine, which was in a tin can, was then poured into the torpedo case, and the torpedo was carefully lowered into the well, which contained at the time about 250ft. of water, until the end of the anchor rested on the bottom of the well. A travelling primer or "go-devil squib" was then prepared as follows:—A tin cone, 14in. in length by 2in. in diameter at the open end, was partially filled with sand to give it the necessary weight. A piece of double tape fuse, 2ft. long, was inserted into a Nobel's treble detonator, and over the detonator and a portion of the fuse a perforated tin tube or sheath was passed. This tube was then inserted through a hole in a strip of tin fixed across the mouth of the conical cup into the sand, so that the detonator was embedded. The sand was then saturated with nitroglycerine, the fuse lighted, and the primer dropped into the well. In about 45 seconds there was a perceptible tremor of the ground, immediately followed by a slight sound of the explosion. After an interval of a second or two there was a gurgling noise, and a magnificent black fountain shot up twice as high as the derrick, upon which all the spectators ran for shelter from the impending shower of oil and water. The well not being a flowing one, the outrush was only of momentary duration, and within a few minutes the drillers were at work removing from the well, by means of the sand pump, the fragments of rock which had been detached by the explosion. On the table are specimens of this rock, which I obtained at the time.

The maximum yield per well is ten barrels per day, and the minimum yield for which it is considered profitable to pump is a quarter of a barrel per day. The yield being in some cases so small, it is usual to pump a number of wells through the agency of one engine, the various pumps being connected with the motor by means of wooden rods. In one instance I saw as many as eighty wells being thus pumped from one centre. The motive power was a 70h.p. engine, which communicated motion, similar to that of the balance-wheel of a watch, to a large horizontal wheel. From this wheel six main rod lines radiated, the length of stroke of the main lines being 16in., and the rate of movement 32 strokes per minute. Some of the wells being pumped from this centre were from one-half to three-quarters of a mile distant, and altogether about eight miles of rods were employed in the pumping of the eighty wells.

The pipe line system in Canada has not been fully developed, and accordingly the well owner has to convey his oil by road to the nearest receiving station. Thus from the Euphemia oil field the oil has to be "teamed" 17 miles, to Bothwell. For the conveyance of the oil by road a long and slightly conical wooden tank or barrel, resting horizontally on a waggon, is employed. These vessels hold from eight to ten barrels of oil. The Petrolia Crude Oil and Tanking Company is the principal transporting and storing company. The storage charge is one cent (½d.) per barrel per month, and the delivery charge two cents per barrel. The petroleum produced in the Oil Springs field is stored separately from that obtained in the Petrolia field.

The storage takes place for the most part in large underground tanks excavated in the retentive clay. These remarkable tanks are often as much as 30ft. in diameter by 60ft. in depth, and hold from 5000 to 8000 barrels. In the construction of the tanks the alluvial soil, of which there is about 18ft. or 20ft. above the clay, is kerbed with wood and thoroughly puddled with clay. On the completion of the excavation, the entire vertical surface is then lined with rings of pine wood, so that the upper part down to the solid clay is doubly lined. The bottom is not lined. The roof of the tank is of wood, covered with clay. The cost of such a tank is about 22 cents (11d.) per barrel, or 1760 dols. (£363) for an 8000-barrel tank, and the time occupied in making such a tank is about six weeks.

The crude petroleum from the Petrolia field usually has a specific gravity ranging from 0·859 to 0·877, while the specific gravity of the petroleum from the Oil Springs field ranges from 0·844 to 0·854.

The oil occurs in the corniferous limestone, and buildings constructed of this stone frequently exude petroleum in hot weather.

Canadian crude petroleum is of a black colour, and possesses a very disagreeable odour, due to the presence of sulphur compounds. These characteristics are shown by the samples on the table, for some of which I am indebted to Mr. James Kerr, secretary of the Petrolia Oil Exchange.

The stills used in the process of refining the crude oil are horizontal two-flued cylinders, 30ft. in length by 10ft. in diameter, provided with six 2in. vapour pipes. The charge is 260 barrels, and the following is an outline of the method of working. Assuming the still to be charged on Monday morning, heating is commenced about 7 a.m., and the naphtha begins to come over about 8 a.m. Of this product about six barrels is obtained in the case of Petrolia crude, or 7½ barrels in the case of Oil Springs crude. The distillation of the naphtha takes from 2 to 3 hours, say till 10.30 a.m. The heat is then increased, and the distillation of the kerosene commences about noon, and continues till about 10 p.m. Of the kerosene distillate about 80 barrels are obtained. The first portion of the kerosene distillate is usually collected separately, is steamed to drive off the more volatile hydrocarbons, and is then mixed with the remainder of the kerosene distillate. The product which then commences to distil is known as tailings. This is collected separately and is re-distilled. The distillation of the tailings continues till about 5 a.m. on Wednesday, by which time about 80 barrels has been obtained. Steam is then passed into the still through a perforated pipe extending to the bottom, and about 21 barrels of "gas-oil" is distilled over. The additional quantity of kerosene obtained on re-distilling the tailings brings up the total yield of this product to about 42 per cent. of the crude oil. The gas-oil is sold for the manufacture of illuminating gas. The residue is distilled for lubricating oils and paraffin.

The agitator in which the kerosene distillate is treated commonly takes a charge of 465 barrels. To this quantity of distillate two carboys of oil of vitriol is added, and the oil and acid are agitated together for 20 minutes. The tarry acid having been allowed to settle is drawn off, and seven carboys more of acid is added. Agitation having been effected for 30 or 40 minutes, the tarry acid is removed as before. Another similar treatment with seven carboys of acid follows, and occasionally a fourth addition of acid is made. The oil is next allowed to remain at rest for an hour, any acid which settles out being drawn off, and cold (or, in winter, slightly warmed) water is allowed to pass down through the oil in fine streams, this treatment being continued, without agitation of the oil, for half-an-hour, or until the dark colour which the oil assumed on treatment with acid is removed. The water is then drawn off, 10 barrels of solution of caustic soda (sp. gr. 15° B.) is added and agitation conducted for 15 minutes. The caustic soda solution having been drawn off, 30 barrels of a solution of litharge in caustic soda is added. This solution is made by dissolving caustic soda in water to a density of 18° B. and then adding the litharge. Agitation with this solution is continued for about six hours, or until the oil is thoroughly deodorised. About 100lb. of sublimed sulphur is then added, and the agitation is continued for another two hours. The oil having been allowed to settle all night, the litharge solution is drawn off, and the oil run into a shallow tank or "bleacher," where it is exposed to the light to improve its colour, and is, if necessary, steamed to drive off the lighter hydrocarbons and raise the flashing point to the legal minimum of 95° F. To raise the flashing point from 73° F. to 95° F. (Abel test) is stated to involve in practice a loss of 10 per cent., the burning quality of the oil being at the same time seriously impaired, and upon this ground the Ontario refiners in 1886 petitioned for a reduction of the test standard.

The average percentage yield of the various products is given in the following table :—

Naphtha	5
Kerosene	42
Gas-Oil	8
Tar	25
Coke	10
Loss (including water)	10
	100

There are a dozen petroleum refineries in Canada, and the annual out-turn of kerosene is about 200,000 barrels of 45 imperial gallons per annum. The total consumption of kerosene in Canada is about 300,000 barrels, one-third of which is manufactured in the United States. The United States oil is subject to a duty of 40 cents on the package and 7½ cents per imperial gallon on the contents, besides which there is an inspection fee of 30 cents per package. Of lubricating oils the out-turn is from 75,000 to 100,000 barrels per annum.

The quality of Canadian kerosene has been greatly improved of late years, but notwithstanding the elaborate process of refining, the oil, though thoroughly deodorised and of good colour, contains sulphur, and of course evolves sulphur compounds in its combustion.

The rules of the Petrolia Oil Exchange provide that refined kerosene shall be of the odour "locally known as inoffensive," and shall "absolutely stand the test of oxide of lead in a strong solution of caustic soda without change of colour."

The "burning percentage" in the case of "Extra Refined Oil," "Water White" in colour, and of specific gravity not exceeding 0·800, is required to be not less than 70 : in the case of "No. 1 Refined Oil," "Prime White" in colour, not less than 60 ; and in the case of "No. 2 Refined Oil," "Standard White" in colour, to be not less than 55.

The "burning percentage" is determined by the use of a lamp thus described :—"The bowl of the lamp is cylindrical, 4in. in diameter and 2¾in. deep, with a neck placed thereon of such a height that the top of the wick tube is 3in. above the bowl. A sun-hinge burner is used, taking a wick ⅞in. wide and ⅛in. thick, and a chimney about 8in. long." The test is conducted as follows :—"The lamp bowl is filled with the oil and weighed, then lighted and turned up full flame just below the smoking point, and burned without interference till 12oz. of the oil is consumed. The quantity consumed during the first hour and the last hour is noted." The ratio of the two quantities is the measure of the burning quality, and the percentage that the latter quantity is of the former is the "burning percentage" referred to.

NOTE ON VISCOSIMETRY.

BY BOVERTON REDWOOD, F.I.C., F.C.S.

The following correction relates to the paper on Viscosimetry, published in the *Journal of the Society of Chemical Industry* for March, 1886.

In my reference to the viscometer described in the *Chemical News* for October 31, 1884, by Dr. William P. Mason, who is now Professor of Analytical Chemistry at the Rensselaer Polytechnic Institute, Troy, N.Y., I stated that the arrangement adopted for eliminating differences due to specific gravity had, I understood, been suggested by Professor H. B. Nason, of the same institute.

From a correspondence I have had with the professors named I find that Professor Nason proposed to Professor Mason, who was then his assistant, to look up the subject of the determination of viscosity, with a view of improving the methods of testing in use, and naturally talked the matter over very freely with him ; but Professor Nason never desired or intended to take credit for anything new in principle or application that was the outcome of the investigation.

Professor Mason is anxious that it should not be thought that he was sailing under false colours when he published his article in the *Chemical News*, and I gladly take this opportunity of removing any misapprehensions that may have arisen from my statement, and of expressing my regret that I should have mistaken the purport of Professor Nason's remarks.

T. WARDLE, ESQ., IN THE CHAIR.

REMARKS ON DYEING WITH CHLOROPHYLL.

BY DR. E. SCHUNCK, F.R.S., ETC.

The author, after referring to a paper on the same subject by M. J. Hartmann and the report thereon by M. Cordillos dit Luzy (*Bulletin de la Société Industrielle de Mulhouse*, xxvi. pp. 283—296), mentioned the difficulties to be encountered in endeavouring to fix the colouring matter chlorophyll on ordinary tissues, in consequence of its extremely fugitive character, and the slight affinity which it manifests for ordinary mordants. He then described a method by which these difficulties can to a great extent be overcome, so as to impart great relative stability to the substance without impairing its fine green colour. Having obtained solutions of compounds which contain, along with colouring matter, various metallic oxides, such as cupric and zinc oxides, he showed that these solutions impart very little colour to cotton, silk, or wool, but that coagulated albumen, gelatin, and more especially the animal products yielding gelatin, such as skin, the ossein of bones, etc., readily attract the colour, and are really dyed when immersed in the solutions. Specimens of leather dyed in this manner were exhibited to the meeting, showing various shades of green, which, in daylight at least, are very pleasing, though by gaslight they share the fate of ordinary greens, and appear dull and dingy. These colours stand the action of soap and dilute acids in the cold, but are not materially improved by the treatment. In the opinion of the author, the tannin of the leather does not assist in fixing the colour. The peculiar compounds of colouring matter with acids and metallic bases, which the author employed in his experiments, do not yield lakes by treatment with ammonia, being in themselves lakes, which dissolve in alkaline lyes without undergoing any change. It would be possible to modify the method so as to make it practicable on a large scale, but the cost would probably prevent it being successfully applied even if the colours obtained were sufficiently bright and intense to make success desirable.

DISCUSSION.

Mr. Grimshaw asked whether the greater tinctorial power of the copper compound of chlorophyll, compared with the zinc compound, resulted in any way from the green or blue colour of copper salts, or whether the proportion of metal present was, as in the case of ordinary mordants and dyes, so small that the metal *per se* was not an element in the tinctorial effect. He presumed the latter was the case, from Dr. Schunck's remarks.

Dr. Bailey remarked that in considering the subject of chlorophyll, as brought forward by Dr Schunck in his interesting paper, one was led to compare with "Lokao," or Chinese green, used as pigment for wall papers, and as this is acted on readily by oxidising and reducing agents, he was curious to know whether the copper compound described by Dr. Schunck had been examined in their relation to such agents. With regard to the greater stability of the copper compounds as compared with zinc, it was a remarkable coincidence that in feathers of a bright red colour there is sometimes as much as six per cent. of copper.

Mr. Riley asked if Dr. Schunck could say what would happen if the acid solution of the copper compound were neutralised with ammonia. Would a pigment green be thrown down, or would the green compound be decomposed? He further inquired whether or not the cost of the extraction and preparation of the colouring matter would prevent its application for tinctorial purposes if a satisfactory method of fixing it were discovered. Referring to the difference exhibited by the copper compound and the zinc compound when exposed to the action of light, he remarked that chlorophyll was not singular in this respect. He mentioned an instance of an aniline blue which, when dyed by means of a mordant of alumina and alizarin oil (same as is used in Turkey-red dyeing), was very fugitive, but when fixed with a tin mordant was comparatively permanent. He also referred to the remarkable action of tartar emetic in the fixation of certain aniline colours. Many of these colours which are fixed by tannic acid will not stand the action of light, or of soaping, unless they are passed through a hot solution of tartar emetic, or some other antimony compound.

Mr. Wm. Thomson said it was an interesting fact that a fugitive colour like chlorophyll should be made more permanent by its combination with copper, whereas with the more stable colouring matter of logwood the action is the reverse—the copper tending to make the colour "logwood black" more fugitive.

The Chairman said he had been struck with the similarity of some of the experiments referred to by Dr. Schunck with experiments carried out by himself in connection with silk dyeing. He would like to ask Dr. Schunck if he had tried other mordants, such as tannin, alum and chromium. With regard to the difference between copper and zinc oxides, he (the Chairman) had found generally in his experience in the dyeing of silk that zinc oxide was practically of no value either in fixing or developing colours; on the contrary, copper was without doubt of value. One of the old fashioned methods of dyeing black was with fustic and logwood, using copper acetate and ferrous sulphate or tannin and logwood. Possibly presence of tannin might have something to do with the greater development of the green colour obtained with the addition of gelatin on leather.

Dr. Schunck, in reply, said: Mr. Grimshaw asks whether the green colour of the solution might be in any degree due to the copper salts? Of course, the colour is to some extent due to the copper contained in it; but the amount, for instance, in this solution of the cupric compound, if it were dissolved in acetic or any other acid, would be so trifling that it would be hardly perceived. Dr. Bailey referred to Lokao or Chinese green, and wanted to know whether there was any connection with this and chlorophyll. Lokao has been tolerably well examined, and it appears that it has no connection with, or relation to, chlorophyll. Mr. Riley asks whether the cost of preparation would be any obstacle to the use of these colours? With regard to chlorophyll, there are difficulties which would prevent its use in practice as a dyeing material, and these difficulties have no doubt often presented themselves to those making experiments with it with a view to its utilisation.

Mr. Riley asked if the action of ammonia had been tried?

Dr. Schunck said he did not know with what object he would suggest this.

Mr. Riley: As a pigment colour to be fixed with albumen by the steaming process, in the same way as chrome green.

Dr. Schunck: No, pigment colours would be produced in the way suggested by Mr. Riley. With regard to tannin, Dr. Schunck said he did not think the tannin in leather had anything to do with the fixing of these coloured compounds. He thought it was the animal tissue which really fixes the colour. The experiments which he made with a view of fixing the green colour on fabrics by means of alumina and metallic oxides led to no result.

Meeting held Tuesday, June 7, 1887.

IVAN LEVINSTEIN IN THE CHAIR.

DETERMINATION OF VISCOSITY OF LUBRICATING OILS.

BY DR. T. TRAUBE.

The determination of the viscosity of oils has given rise to several discussions (see this Journal, vol. v. 121—133, 148—149, and 359), in view of which I think it desirable to give a preliminary description of the essential features of my own method of determining the viscosity, a full and exhaustive account of which will appear shortly in the *Zeitschrift des Vereins Deutscher Ingenieure.*

I will state at once, that I fully agree with the views of Professor E. J. Mills, that we can only achieve satisfactory results in the determination of viscosities by closely approximating to Poiseuille's method.

There is one point, however, not sufficiently noticed by Professor Mills, which has given rise to more errors and consequent disagreements in the results obtained by the instrument at present in use than the non-compliance with many other conditions demanded by theory.

The point is this: According to theory, it is not permissible to compare directly the times of efflux of heavy and light oils, and still less the times of efflux of oils and water observed in one and the same apparatus. Though the results of observations made with different apparatus may yield apparently concordant results, the direct comparison of times of efflux thus obtained will be liable to lead to serious errors.

This remark will be better understood, if we compare the formula given by Poiseuille for the coefficient of friction in narrow tubes:

$$\eta = \frac{\pi p r^4}{s.v.l} t.$$

with the enlarged formula of Hagenbach:

$$\eta = \frac{\pi p r^4}{s.v.l.} t - \frac{v.s}{2 g \pi l} \cdot \frac{1}{t}$$

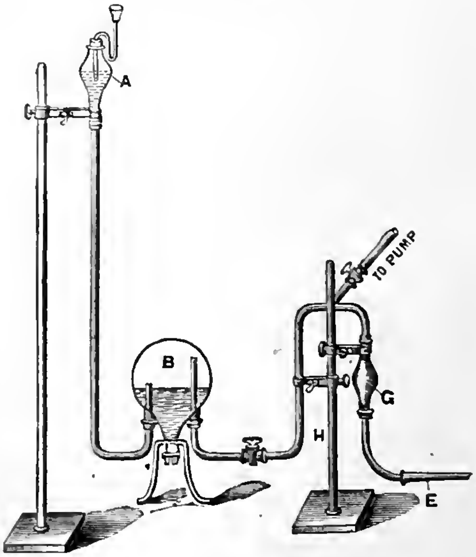
in both of which formulas, η is the co-efficient of friction, t the time of efflux, v the volume of the fluid discharged, p the hydraulic pressure, l the length, and r the radius of the capillary tube, and s the specific gravity of the liquid.

The comparison of these two formulas will show at a glance, that the simple one of Poiseuille cannot be considered applicable to the viscosimeters at present in use; at any rate, that the time of efflux is not directly a correct measure of the coefficient of friction, since even when the pressure is presumed to be equal, Hagenbach's correction (*i.e.*, the second term in Hagenbach's formula) assumes very different values for liquids for which the time of efflux differs considerably; or, what is the same thing, for liquids of different viscosity.* Consequently, in apparatus with tubes of such diameter that the time of efflux is still approximately proportional to the viscosity when thick heavy oils are used, that will be so no longer for thin oils, and still less for water.

It has been proposed by others, and at first sight the suggestion appears a practical one, to refer the viscosity of oils to a pure oil or to glycerol, or to a certain solution of sugar, instead of referring it to pure water; but all experiments which I have made in that direction have shown that it is very difficult to obtain fluids of sufficiently constant qualities; that small differences in specific gravity are productive of very considerable differences in the viscosity. For this reason, I think it is impossible to choose a better standard fluid than pure water.

I shall presently show how the errors I have mentioned are avoided in my method, of which the following is a short description:—

The annexed sketch represents the apparatus: A is a Mariotte bottle filled with water, which serves to compress air in the reservoir B and to keep the pressure constant. B is connected by means of pipe and cock to the efflux apparatus H, consisting of the bulb G, provided with two marks, to permit the measurement of volume of liquid to be discharged, and of the capillary tube E. The reservoir B is filled by means of a pump attached to branch and stopcock.



If the tube E is so narrow that the correction of Hagenbach becomes very small, almost equal to zero, the time of efflux may be considered to be proportional to the viscosity.

If that result is to be obtained, we must select a wider tube for heavy oils than for lighter ones or for water.

If with a very narrow tube we determine the times of efflux of water, and of another fluid the viscosity

---

* In very many, perhaps in most of the viscosimeters in use, Hagenbach's correction amounts to more than the value of the first part of the formula itself.

of which lies between that of water and of a light oil, say glycerol of 80 per cent., and then in a wider tube we compare glycerol of 80 per cent. with glycerol of 100 per cent., and in a third still wider tube compare the glycerol of 100 per cent. with a viscous oil, it is easy to fix a corrected time of efflux for water for every tube, without knowing the dimensions of the tubes.

As these adjustments are difficult and troublesome, I have made arrangements with the firm, C. Gerhardt, in Bonn, to keep a stock of properly adjusted apparatus.

With two or three different discharge tubes attached to the same pressure apparatus it is thus possible to determine by one single and easy experiment the specific viscosity of any oil. The apparatus is easily cleaned by means of ether.

The following table shows for three different apparatus, A, B, C, the times of efflux *t* in seconds, the viscosity *v*, the most viscous oil being assumed 100.

	A.		B.		C.	
	t″	*v*	*t*″	*v*	*t*″	*v*
Cylinder lubricating oil ..	155·5	100·0	472	100·0	2960	100·0
Rapeseed oil	79·0	50·8	242	51·3	1503	50·8
Olive oil..................	71·7	46·1	222	47·0	1361	46·1

The diameter of the tubes were A = 1·5mm., B = 0·8mm., C = 0·5mm.; the length of the tubes and the volumes of oil discharged were nearly alike.

The figures in this table prove that for oils of such viscosity tubes of a diameter of 1·5mm. may be used, but when light oils or water were used considerable differences were manifest.

The figures show plainly that by means of suitable tubes the viscosity of any oil may be determined exactly in from two to three minutes.

For the determination of viscosities at higher temperatures suitable air bath is provided, which is also supplied by the firm Gerhardt, of Bonn, constructed in either copper or iron.

With regard to the dimensions of the tubes and the correctness of the values obtained, the *Zeitschrift des Vereins Deutscher Ingenieure* must be consulted, where another method is also detailed which offers advantages in many cases.

DISCUSSION.

Dr. **Bailey** said that it seemed to him the paper referred viscosity to specific gravity, whilst it had been shown by Graham long ago and by others that the rate of flow in narrow tubes was not entirely dependent on the specific gravity, but that it was dependent on the chemical character of the substance. He thought, therefore, in comparing the viscosity of oils it seemed likely that the chemical character of the oil had an influence on the rate of flow, and it would be interesting to know whether this was the case or not. Should it be so, the use of tubes of different diameters as suggested by the author would not be received with confidence.

A DOUBLE SULPHATE OF LEAD AND ALUMINA.

BY G. H. BAILEY, D.SC., PH.D.,
The Owens College.

Some weeks ago my friend, Mr. Cecil Watson, of Foxhill Bank Print Works, was good enough to forward to me some crystals which he had noticed in a mordanting liquor. The mordanting liquor in question (nitroacetate of alumina) is made by dissolving up alum, lead acetate and lead nitrate in water and allowing to settle. The clear liquor is of the strength 20° Twaddell, and is used as a mordant for alizarin, which is especially valuable from its slow dissociation on steaming.

Lead sulphate separates out of the mordanting liquor, and in winter there appear also beautiful crystals of the regular system, crystallising in fact in octahedra in cruciform aggregates like alum. They are, however, not transparent, and are quite unaltered by exposure to air. The lead was determined as sulphate by digesting the finely powdered crystals with excess of sulphuric acid, the alumina appearing in the filtrate; the sulphuric acid by treating with excess of lead nitrate and nitric acid and weighing as lead sulphate. The water of crystallisation is almost entirely driven off at 150°, but the last traces only at 250°. The crystals contain the merest trace of nitric acid.

Analysis determines these crystals to have the composition $PbAl(SO_4)_2 10H_2O$. We have here a most interesting addition to the analogies already noticed in the chemical relations of lead, thallium and the alkalis.

The alkalis form alums, whilst thallium, resembling on the one hand the alkalis and on the other hand lead, forms a well defined alum; and in this salt we have what is essentially a lead alum formed under special conditions of concentration and temperature.

Note to the above Paper.—The sulphuric acid determination referred to above has been carefully repeated, and the result of the full analysis is appended:—

	Found.	Calculated for $Pb_2Al_2(SO_4)_5 20H_2O$
Pb	31·50	31·65
Al	4·34	4·13
SO_4	36·41	36·70
H_2O	27·34	27·52

The body, therefore, resembles the alums in composition as in crystalline form, and lead is as might have been expected divalent.

For the analysis of the salt, I am indebted to Mr. Read, a student of Owens College.

DISCUSSION.

Mr. **George E. Davis** asked if Dr. Bailey had established the formula $PbAl(SO_4)_2$ by analysis of the crystals, as the formula given was not consistent with that of the alums. Lead was a dyad, while aluminium was triadic, so that there was an uneven number of atomicities to be satisfied on the side of the bases, and an even number on the acid side.

Dr. G. H. **Bailey**, in reply, said it was well known that crystals of a mixed character did form, and it was impossible to say whether they were simple in character or not unless sections were made and examined optically, and in this case it was impossible to do so inasmuch as they were not transparent. The only check at disposal was the fact that several analyses made on different portions gave results agreeing amongst themselves. With regard to Mr. Davis's remarks he was yet in some slight doubt as to the sulphuric acid since the two determinations already made did not agree well enough. The result, however, was in accordance with the formula given, and should lead be divalent (and it would be certainly strange, as Mr. Davis remarked, were it otherwise) they would require half a molecule more of sulphuric acid, and double the formula. He apologised for bringing, under pressure of work, a somewhat incomplete analysis before the Society, but would repeat the sulphuric acid determination. (See above). In reply to Dr. Dreyfus, the crystals were not soluble in water.

A DELICATE TEST FOR BISMUTH.

BY F. B. STONE.

THE delicacy of the following test for traces of bismuth has not, so far as I am aware, been noticed. It depends on the fact that a strong solution of potassium iodide produces a bright yellow colour when added to a very dilute solution of bismuth sulphate, containing only a small quantity of free sulphuric acid. So delicate is this test that 0·00001 grm. of bismuth oxide in 10cc. (=1 part in 1,000,000) will show a distinct colouration on addition of a few drops of strong solution of potassium iodide. Very small quantities of bismuth can also be estimated colorimetrically by means of this test, as the following results will show:—

A standard solution of bismuth sulphate, containing 0·0001grm. of bismuth oxide in each cc., was prepared, and six unknown quantities of this solution were measured off to test the accuracy of the assays.

Number of cc. of Standard Solution of Bismuth Sulphate required. (Each cc. 0·0001grm. Bi_2O_3.)		Test Quantities taken. (Each cc. = 0·0001grm. Bi_2O_3.)	
cc	Grms. Bi_2O_3 Found.	cc.	Grms. Bi_2O_3 Taken.
1·1 =	0·00011	1·0 =	0·0001
1·3 =	0·00013	1·5 =	0·00015
2·1 =	0·00021	2·0 =	0·0002
3·5 =	0·00035	4·0 =	0·0004
7·3 =	0·00073	7·0 =	0·0007
9·2 =	0·00092	10·0 =	0·001

The above results are quite as accurate as a colorimetric process can be expected to give.

As little sulphuric acid as possible was used for making up the standard bismuth sulphate solution, and the assays were in every case made up to 10cc, to which was previously added 1cc. of a 2p.c. solution of sulphuric acid.

This test is also very convenient for detecting traces of bismuth in copper, for although a small quantity of bismuth is dissolved, when ammonia and carbonate of ammonia are added to a bismuth solution, this is not the case when a large amount of copper and also a small quantity of iron are present. Quantities as small as 0·0001grm. of bismuth in 10grms. of copper (= 0·00001 per cent.) showing quite distinctly. The precipitated carbonate of bismuth is washed with a little dilute ammonia and carbonate of ammonia, till the filter is quite free from blue colour, dissolved in a very small quantity of dilute sulphuric acid, a few drops of potassium iodide added, and afterwards a few drops of sulphurous acid till the solution smells distinctly, to remove the yellow produced by the liberation of iodine due to the ferric sulphate present.

DISCUSSION.

Dr. G. H. BAILEY could not see any dependence on a colorimetric determination. If a sample of pure sulphate of bismuth was obtained, then he thought the best method of determination would be evaporating to dryness and weighing, but to use potassium iodide as a colorimetric test under any other conditions would surely be a most dangerous proceeding, because such a number of circumstances of which there could be no previous knowledge might bring about the separation of iodine, and the author gives no sufficient precautions for avoiding all substances which might act as oxidising agents. If he did so he would find he had as much trouble, because it would be very difficult to make sure that one had a solution in which no action is taking place. On adding sulphurous acid in the presence of copper one would certainly get cuprous iodide separating which would probably interfere with the sharpness of the reaction.

Dr. WATSON said: The test here brought under their notice might be useful as a confirmatory test for bismuth, but seemed to be capable of a very limited application. The proposal as a test for bismuth appeared to him to be a new suggestion. He was accustomed to use for the purposes for which the new test was available an exceedingly delicate and more characteristic test, which he thought would be found preferable to the one under discussion. It was performed as follows:—To a small quantity of the solution containing bismuth, which may be neutral or slightly acid, is added a small quantity of lead nitrate, and then a solution of potassium iodide, causing a precipitation. The presence or absence of bismuth is judged from the colour of the precipitate. If bismuth is absent the colour is, of course, a lemon yellow. If bismuth be present the colour varies with the relation between the amounts of bismuth and lead present from a light orange to a deep Indian red. With careful manipulation very distinct indications could be obtained with a few drops of a solution containing less than one millionth of bismuth. He was unable to say to whom credit was due for the introduction of the method, but he had made use of it himself for many years past.

Mr. WATSON SMITH, who read Mr. Stone's paper, remarked, in reply to Dr. Bailey, that Mr. Stone only claimed usefulness for it as a test for traces of bismuth, which practically defied further gravimetric manipulation, owing to their smallness. He had understood the author that these traces were first to be separated from other constituents likely to effect results before titration, and as the author gave tabulated results indicating a considerable accuracy, they must accept his method, at least for what it demonstrated itself to be worth. The test, in presence of copper, was only intended by the author to be a qualitative one.

◆

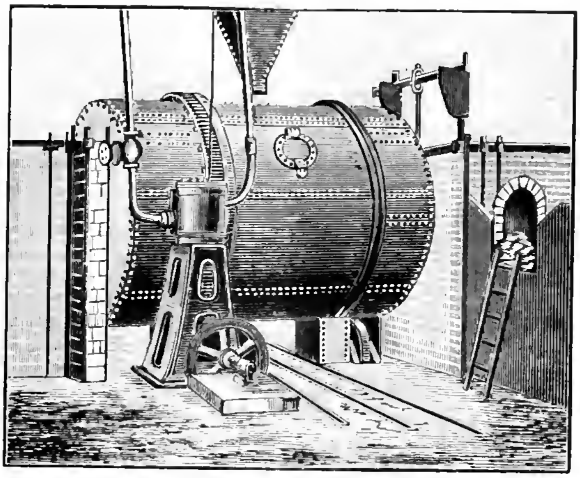
A NEW MONSTER REVOLVING BLACK ASH FURNACE AND THE WORK DONE WITH IT.

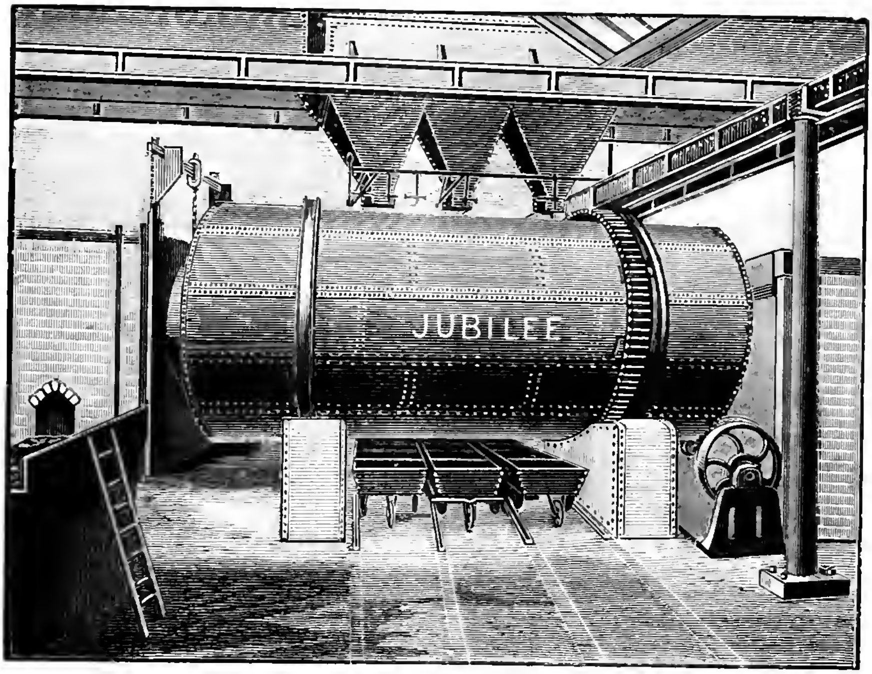
BY WATSON SMITH,

Lecturer in Chemical Technology in the Victoria University, etc.

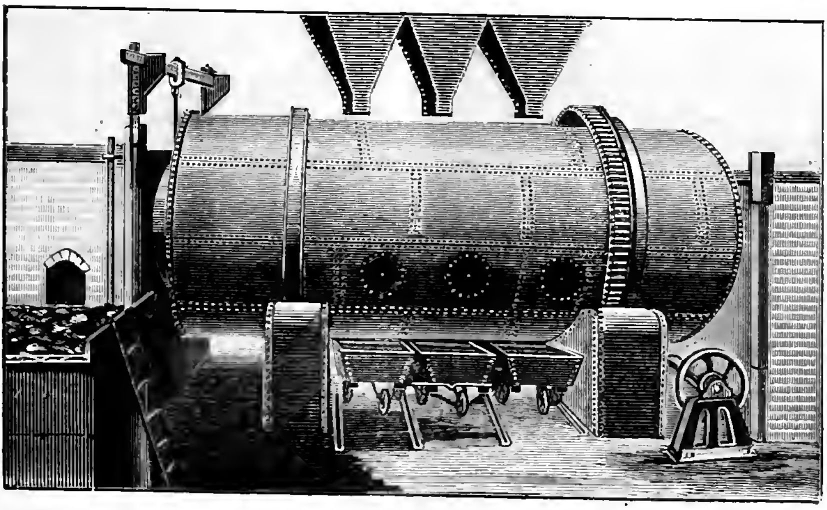
THE Widnes Alkali Company, Limited, to which I am indebted for permission to describe this latest addition to a family of revolving black ash furnaces, of late not only increasing in number, but also individual size, has kindly allowed my friend, Mr. H. Baker, to photograph the great revolver in question, and I have pleasure now in throwing on the screen a picture of it, and also one of a revolver of ordinary size, so as to render a comparison possible. The revolver of ordinary size measures at most 18½ft. long, with a diameter of 12½ft. The boiling-down pans connected with such a furnace measure 60ft. in length. Each charge contains four tons of salt cake, and some of these revolvers get through 18 tons of salt cake per day and consume 13cwt. of coal per ton of cake decomposed.

With regard to the larger revolver, it may be just said that the Widnes Alkali Company has not at





JUBILEE



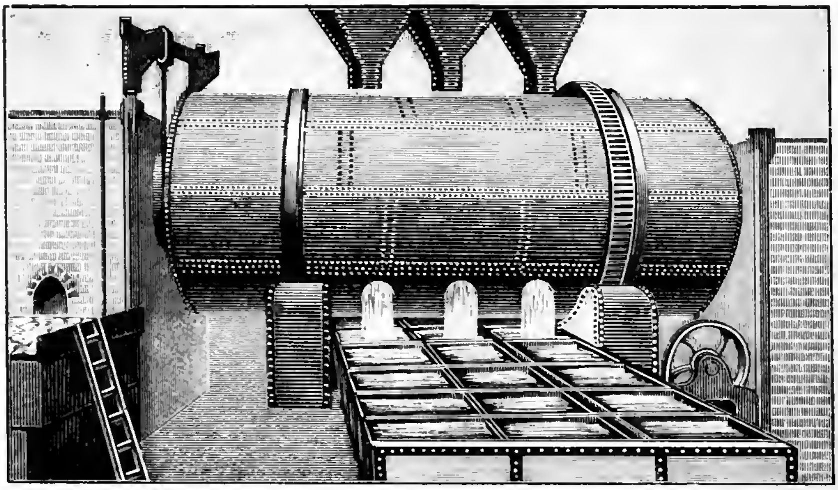
once sprung to the adoption of a furnace of the immense size to be presently given, but in 1884 it erected a revolver only about 3ft. to 4ft. short of the length of that one, and having two discharging holes. The giant revolving furnace to be described measures in length 30ft. and has a diameter of 12ft. 6in. Inside length is 28ft. 6in., with a diameter of 11ft. 4in. It is lined with 16,000 fire-bricks and 120 fire-clay blocks or breakers, weighing each 1¾cwt. The bricks weigh per 1000 about four tons. The weight of saltcake per charge (*i.e.*, contained in each charge of saltcake, limestone, mud, and slack) is 8 tons 12cwt. For 100 tons of saltcake charged, there are also charged about 110 tons of lime-mud and limestone, and 55 tons of mixing slack. In a week of seven days about 48 charges are worked through, weighing of raw materials about *25 tons per charge.* The total amount of saltcake decomposed weekly is about 400 tons, and may be reckoned as yielding 240 tons of 60 per cent. caustic soda. As regards fuel used for firing, this may be put down as 200 tons per week, or about 10cwt. per ton of saltcake decomposed. Also with regard to the concentration of liquor from 20° Tw. to 50° Tw., there is sufficient of such concentrated liquor evaporated down to keep three self-fired caustic pots working, which are boiled at a strength of 80° Tw. Were it not for this liquor, no less than seven self-fired pots would be required to do this work, showing a difference of 80 tons of fuel.

The question may be asked, "Why increase the size of these huge pieces of apparatus?" The answer, I apprehend, is that owing to competition and reduction of prices, greater efforts are necessary to reduce costs. With automatic apparatus like the black ash revolver, we may consider no very sensible addition of man-power would be needed, in passing from the smallest-sized to the largest-sized revolver. Then, again, we may, reckoning a certain constant amount of heat lost per each revolver furnace of the small size, consider that if we doubled the size of such revolver, we should lose by no means double the amount of heat lost with the small apparatus; but only the same as that lost in the small furnace *plus* a certain fraction of that quantity, which will be smaller the better and more efficient the arrangements are. Then, again, there is an economy in iron-plate for such a large revolver; there is economy in expense on the engine-power and on fuel consumed, as well as in wear and tear.

Just to mention fuel alone, we saw that with an ordinary large-sized revolver, the coal consumption was 13cwt. per ton of salt-cake decomposed in the black ash process; but with the giant revolver we have been describing, that consumption is reduced to 10cwt. per ton of cake decomposed.

The question will be probably asked, how is it possible to get a flame from one furnace to carry through such a long revolver and do its work in fusing the black ash mixture effectively from one end to the other? The furnace employed viewed in front looks very like an ordinary revolver fireplace, but at the side, thereof in line with the front of the revolver, at which the discharge of the "crude soda" takes place, there are observed to be three "charging holes," rather than doors, through which fuel is charged from a platform directly into the furnace through those holes.

The furnace is of course a larger one than furnaces adjusted to revolvers of the usual size; but the effect of one charging-door in front and three at the side, which after charging are "banked" up with coal, with the exception of a small aperture above for admission of air, is very similar to that sometimes adopted in the laboratory for increasing heating effect by joining several Bunsen lamps together to produce one large powerful flame. In this case, the four charging holes represent, as it were, the air apertures of the several Bunsen lamps. Of course the one firing-door at front would be totally inadequate to supply and feed a fire capable of yielding a flame that would be adequate for the working of so huge a revolver. As an effort of chemical engineering, it is a very interesting example of what skill and enterprise in that direction alone will do in reducing costs, without in the least modifying the chemical reactions taking place.



◆◆◆

THE FRACTIONAL REDUCTION OF ORTHO- AND PARANITROTOLUENE, AND NOTES ON THE QUANTITATIVE ANALYSIS OF ORTHO- AND PARATOLUIDINE.

BY T. MINIATI, H. BOOTH AND J. B. COHEN.

It is well known that aromatic nitro-compounds on reduction yield amido-compounds. When toluene is nitrated, two isomeric nitrotoluenes, ortho- and paranitrotoluene, are the principal products formed, and always occur in varying proportions in commercial nitrotoluene. On reduction they are transformed into the isomeric ortho- and paratoluidines. It was thought interesting to determine which of these isomeric nitrotoluenes is the more readily reduced, or whether reduction goes on *pari passu* in both cases. The principle of the method employed for determining this is as follows:—Supposing equal quantities, say 10grs., of pure ortho- and paranitrotoluene are taken, and tin and HCl sufficient to reduce half the total quantity (10grs.) added, then it is evident that the product will consist of one of three things. It will contain only orthotoluidine and only paranitrotoluene—*i.e.*, if the orthonitrotoluene is reduced first, or if the inverse reaction occur, only paratoluidine and orthonitrotoluene; if both are reduced, the toluidine and nitrotoluene, obtained after reduction, will consist of mixtures of the two isomers. An analysis of the unattacked nitro compounds, or the toluidine formed, will then show with which isomer and to what extent reduction has occurred. From a series of experiments, which are not yet completed, it appears that para- and orthonitrotoluene are acted on *concurrently* and not separately. The results have, however, not been of a nature to be able at present to state definitely the rate at which reduction has occurred, nor has the action been extended to various reducing agents, which may possibly give different results. Before beginning the analytical work it was necessary to determine whether the reduction could be so regulated that approximately the same quantities of nitro toluene could be reduced with a given quantity of the reducing agent. With care this may be readily accomplished. The separation and isolation of the nitrotoluene and toluidine is a simple though tedious operation. Among the various methods tried, the following is satisfactory:—After reduction, the resulting acid solution is distilled in steam, and the unattacked nitrotoluene driven over, the toluidine remaining behind. The toluidine solution is freed from Sn by H_2S and filtered. If the precipitation is done hot, the sulphide settles down in a dense form, and is less difficult to filter. The filtrate is then made alkaline and distilled in steam, and the toluidine distils. Both distillates are extracted with ether, the ether distilled off, the residue dried and weighed. The first gives the weight of nitrotoluene, the second that of the toluidine. All that is necessary for the analytical part is (1) to be assured of the purity of the original materials, and (2) of the reliability of the method of analysis. The para- and orthonitrotoluenes were obtained from C. A. F. Kahlbaum. The para was in fine crystals, melting at 54°, the ortho, as might be expected, contained about 15 per cent. of para-compound, estimated by reduction and analysis by Rosenstiehl's method. To arrive at a result it is not necessary that both products after reduction should be analysed. Having the weight of the nitrotoluene and the toluidine, an analysis of the one or the other, and the determination of the quantity of ortho and para present in it, will suffice to find exactly how the reduction has gone. The simplest method which naturally suggests itself is the analysis of the resulting nitro-compound, which does away with the tedious extraction of the toluidine. A few experiments were made to determine how far the method of freezing might answer. The para-nitro-compound is solid at ordinary temperatures, the ortho-nitro liquid. Various mixtures of the two were made, and it was found that when not more than 50 per cent. of paranitrotoluene was present, the mass at the ordinary temperature was semi-solid. In the proportion of four parts para to one part ortho, the mass is quite hard. In a mixture of salt and snow (about $-15°$ to $-20°$), when only 30 per cent. of the para-compound is present, the mixture becomes nearly solid. But on draining the frozen cake, on a porous tile, placed in a metal vessel, surrounded by a freezing mixture, only about two-thirds of the total amount of the para-compound could be regained.

Some little time ago a method described by Mr. P. Schoop appeared in the *Chemiker Zeitung* (No. 9, p. 1785), for the quantitative analysis of ortho- and paratoluidine, based on the different solubilities of the acetyl derivatives in water, first pointed out by Weith and Merz in 1869 (*Ber.* 2, 433).[*] Our results by this method were by no means satisfactory, possibly because the proportion of para compound taken was considerably smaller than usually occurs in the commercial product. But this can scarcely be cited as an apology for the method. Two determinations gave the following results—

Taken.	Found.	Melting Point.
1. 9·75grms. orthotoluidine 0·25grm. paratoluidine	2·3950 acetoluide	107° = 1·71grms. toluidine.
2. 9·75grms. orthotoluidine 0·25grm. paratoluidine	3·1325 acetoluide	110° = 2·25grms. toluidine.

Now, as the melting point of the para compound is 147°, and the ortho 107°, it is very evident that in the first instance the acettoluide consists of nearly pure ortho compound. In fact, it is not readily seen how, if 1000 parts of water dissolve only 8·6 parts orthoacettoluide at 19° (which corresponds to 5·8 parts orthotoluidine) as stated, it is possible that in a mixture containing 9·75grms. orthotoluidine, all the orthotoluidine can be dissolved in 800cc. of water. And yet the author of the method says that he obtains results to 0·5 per cent. for all proportions of mixed toluidines. On the other hand, in reducing mixtures of ortho- and parnitrotoluene, and analysing the product by the above method, we have often found that little or no para compound was precipitated on addition of water, although a considerable quantity was certainly present, as we subsequently proved by employing Rosenstiehl's method. It is difficult at present to say to what this is due.

The other method which we tried and found to give reliable results when employed with certain precautions, is the well-known one of Rosenstiehl (*Ann. Chem. Phys.* 26, 249). It is based on the different solubilities of the bioxalates of ortho- and paratoluidine in ether. The para-compound requires 6660 parts ether for complete solution; the ortho compound is very much more soluble, requiring only 200 parts of ether. Rosenstiehl makes up a standard solution of oxalic acid in anhydrous ether, free from alcohol, so that each cc. = 0·005grm. toluidine. The number he gives is slightly wrong. Instead of 1·062grms. it should be 1·059grms. of anhydrous oxalic acid, or 1·177grms. of the hydrated acid per 250cc. Rosenstiehl determines the end of the reaction by running the ethereal solution of oxalic acid into 0·2grm. of toluidine, dissolved in 80grms. ether until no further precipitate is observed. We found this to be almost impossible to carry out practically, as the precipitate being light, does not readily settle or attaches itself to the sides of the vessel and masks the effect. It is equally impossible to determine the end of the reaction by means of litmus paper or litmus solution, as recommended by Lorenz (*Ann.* 172, 1190). The change of colour is only very gradual.

The only method we found practicable was to add excess of oxalic acid solution, bring the precipitate on to the filter paper, wash three or four times with ether, and weigh on a watch glass. Any residue

---

[*] 10cc. toluidine and 10cc. acetic anhydride are heated together in the oil-bath for two hours to 140° C. 30cc. glacial acetic acid are then added, and the mixture poured into 400cc. water, and washed out with 400cc. more water. The mixture is allowed to stand 48 hours, filtered, washed with dilute acetic acid, dried at 90° and weighed.

remaining in the flask (and very often the precipitate stuck to the sides), and any residue in the filter paper were dissolved together in water and titrated with decinormal potash solution.

By proceeding in this way reliable results may be obtained. With paratoluidine, m.p. 45°, we found that precipitation was not complete unless the mixture was allowed to stand 12 hours. At the end of this time the whole of the para compound is thrown down as oxalate.

With pure orthotoluidine (samples were made by ourselves and also obtained from Kahlbaum and Schuchardt) there is no immediate precipitation, but on standing 12 hours from 4—5 per cent. of the ortho compound crystallises out.

It therefore follows that in performing the analysis the error due to precipitation of the ortho compound must be allowed for if the solution stands 12 hours, or the error due to incomplete precipitation of the para compound must be allowed for if the precipitate is filtered immediately. The better method, therefore, would be to obtain an approximation of the amount of para compound present in one determination, and then run in just sufficient oxalic solution to precipitate this quantity, and let stand 12 hours. The error due to the precipitation of the orthotoluidine will then be reduced to a minimum. Most of the practical part of the work was carried out by Mr. Miniati, and Mr. Booth has made a series of experiments on Rosenstiehl's method.

DISCUSSION.

Dr. **Dreyfus** said if the method of partial reduction referred to by Dr. Cohen could be carried out it would be a very great benefit to the manufacturers of toluidines, but he hardly thought that the method as it stood at present would give practical results. A better method of preparing toluidines would be to effect the separation of the ortho- and paratoluidines from commercial toluidine, which contained a mixture of the two. Various methods were employed for effecting that separation, which varied at the different works where the methods were carried out, and such methods were kept secret by the works employing them. As far as he knew, the principle of the separation methods rested in the fractional saturation with acids. There had been a method patented by Dr. Loewy for the separation of the toluidines by means of phosphates, but from his experience he considered that method long and tedious, and he did not think that it had been found useful in practice. The methods which he knew had been successful in the production of a fairly pure article rested, as he had before stated, on the fractional saturation with acid.

Dr. **Cohen**, in reply, said that unless it was known beforehand it was quite impossible to carry out the distillation, which certainly gave very fair results in the laboratory.

NOTES ON SOME PLANTS POSSESSING PROPERTIES USEFUL IN MEDICINE AND INDUSTRY, FROM THE CONGO.

BY R. C. PHILLIPS.

The following vegetable products of Africa, not articles of commerce, have attracted my attention during a long residence on the West Coast :—The *Pawpaw*, *Cassia Occidentalis*, *Euphorbias*, *Vernonia Febrifuga*—a plant named by the natives *Saaka*—and some others, on which I propose to make a few notes.

Pawpaws.—These trees are known as yielding a juice with properties similar to pepsin. The effect of making tough meat tender is very remarkable ; half-a spoonful of the juice mixed with a tureenful of water will, in the course of four or five minutes, completely soften a tough joint of old goat, an old duck, or other meat. If the action be unduly prolonged for, say, twenty minutes, the meat will have the appearance of being boiled to rags. Meat thus treated is said to putrefy rapidly if not cooked at once. Wrapping meat in the leaves of the tree is said to produce the same effect in the course of a night. In his "Histoire Naturelle," Dr. Chenu states that the juice is reputed to remove freckles. I have never had the opportunity to verify this, but from its energetic action on flesh, it is not improbable. The seeds have the taste of cress. I have tried to dry the juice by wounding the fruit and catching the milk on plates, and drying in the sun, but the trouble was that the dried product refused to redissolve in water or alcohol. The taste of the water showed that some portion of the dried fruit had undergone solution, but only to a small extent. I then caught a number of drops of the milk in a glass of water, and observed that the solution was only partial ; a precipitate of albuminous appearance was formed, which would not disappear on the addition of a considerable quantity of alkali or acid. I used spirit—brandy—in a similar manner, but with the same result. Obviously the active principle is not the insoluble portion of the milky juice ; but, when all is dried together, the soluble portion may be prevented from dissolving by its association with the insoluble portion, or may itself become changed and insoluble. I never had the opportunity of ascertaining if this be the case. The pawpaw grows freely on most parts of the coast near the Congo ; the best place is the newly - acquired Portuguese territory of Cabinda. The vexatious conditions imposed by the Independent Congo State, and the inferiority of the territory, negative success in those parts.

Further Note on the Pawpaw.—I once knew of a number of pawpaw seeds being thrown away ; a large number took root — perhaps 100—but all were males. This would be an inconvenient experience in planting.

Cassia occidentalis.—This plant grows freely on most parts of the coast, the seeds ground after roasting being a fair substitute for coffee. They are reputed to possess pectoral qualities when thus used, and do not cause sleeplessness, as is so much the case with coffee. I have often used these seeds when short of coffee, and have offered this "coffee" to others without having the substitution discovered. The roots are bitter and reputed febrifugal.

Euphorbias.—These grow in great abundance on many parts of the coast, and their milky juice is well known as a drastic purgative. It is not now made use of in medicine, through, I am informed, its variability of effects. One species, the Cassoneira, is used by the natives of Kinsembo to stupefy fish in their river ; the fish are then taken at palisades which are formed across the river. This drug might probably be of high service in homœopathic therapeutics if properly proved. The Cassoneira is used by the Misorongo tribes to form hedges round their towns, its immense bushes forming a perfect barricade against native tribes, who greatly fear getting the juice in their eyes, the result of which would be temporary, if not permanent, blindness. The branches are very brittle, and bleed copiously when broken. The columnar Euphorbias yield a similar juice in great abundance and with probably analogous properties.

Vernonia febrifuga (Soyaux).—This tree possesses an intensely bitter bark ; but I am unaware by what means Soyaux made out its febrifugal properties; probably from some of the native herbalists. It might be worth investigation.

Saaka.—This is a native bush which would probably repay cultivation and improvement. The fruit is spindle-shaped, some ⅞in. in length, red skinned, and has an agreeable pulp enclosing the seed. At first sight, there is nothing special to recommend it to notice, but it will be found that, although not particularly sweet, it has the remarkable power of making any fruit eaten afterwards taste very sweet. It is usually eaten with limes, but oranges, pine-apples, and mangoes are sweetened by Saaka even an hour after eating it, and when all taste of the fruit has left the mouth. Vinegar and dilute mineral acids show the same phenomenon.

Rubber Plants.—The rubber-bearing plants are not cultivated; the natives simply select such as they please for tapping for the milky juice. It has been suggested to me that the trees might be profitably cultivated and methodically tapped, avoiding waste and the intermixture of bark and other impurities. There are several species of rubber-bearing trees, the best of which, I am told, is a straight-trunked tree of compact habit, which I well know by sight, and, if it be true that this is the best rubber-yielder, I should think that it would be very suitable for plantation. Some other species of rubber-bearing plants are thin-stalked bushes, running about among the other bush, and unsuited for orderly culture. Among the promises of extended trade when the upper Congo is exploited, we are regaled with accounts of vast forests of rubber trees that will yield fabulous amounts of rubber. I, in turn, can point to immense woods of these trees not five miles from the coast, but hardly touched by the natives. Unless plantations are made by Europeans, the yield of rubber on the coast can increase but slowly—nay, it may easily diminish instead of increasing. What is of the first importance is a population, large, friendly and intelligent, to permit of increasing commerce: a little thought in this direction would be of far more value than all the egregious announcements of unlimited trade for those with enterprise enough to open up the upper river, with which the world has been lately entertained.

Castor-oil Plants grow in abundance, but are not used commercially; perhaps they are more easily obtained from America. It has been said that the oil flavours the other cargo of the ship in which it may be exported; this is, however, only hearsay; certainly nobody has attempted the experiment during the last fifteen years, and probably for many years previously.

Indigo.—There are many plants of the Indigofera family, and through the kindness of Mr. Watson Smith, who sent me seeds, I know that indigo may be cultivated; the irregularity of the rains, and absence of convenient supplies of water, militate against the growth of small plants whose roots penetrate only a small distance below the surface of the ground.

Nkasa.—This tree is described by botanists under the name of "Sassy" tree, its powdered bark being used by the natives for their ordeals by poison. The effect of the bark is sometimes of the nature of an emetic, sometimes it produces purging, and I have seen one instance of comatose state produced. It is so seldom that a white man is present at these ordeals, that we know little with certainty about the action of this drug; but it certainly has very active properties which the homœopath would soon turn to account. Compare the cardinal importance of rhus, which is of analogous use in Madagascar.

Besides the foregoing, there are various other products obtainable, the chief difficulty of developing which lies in the fact that the workers are employed in other pursuits, which they will not be induced to leave, except with the plainest demonstration that the new occupation will be more profitable. This is not easy to give to the native, who is conservative of old customs, and sceptical concerning anything new.

MR. J. NEILSON CUTHBERTSON IN THE CHAIR.

THE ESTIMATION OF IRON IN CHARS.

BY ROBERT DAVIDSON.

THE estimation of iron by means of stannous chloride has been fully investigated by Fresenius and others, but only where it exists in large quantities. So far as I am aware, no one has yet tested the accuracy of this process in the case of substances, such as animal charcoal, containing only from 0·1 to 1 per cent. ferric oxide. Some experiments which I have made in this direction I now take the opportunity of bringing before you.

A standard solution of ferric chloride was prepared containing 0·01grm. Fe_2O_3 per cc.

The stannous chloride was made up of such a strength that about 2·5cc. equalled 1cc. of the standard Fe solution, and was always prepared immediately before use.

The iron solution was delivered into a 100cc. flask with 5cc. hydrochloric acid (sp. gr. 1·185) and 10cc. water. The solution was maintained just at the boiling point during the titration. The end reaction is very delicate, one drop of the $SnCl_2$ being sufficient to discharge the colour.

The following are the results:—

Fe_2Cl_6 Solution.	$SnCl_2$ Consumed.
1·0cc.	2·63cc
1·0	2·63
0·5	1·32
1·6	1·16
0·9	2·35
0·4	1·10
2·2	5·80
1·1	2·90

The mean experimental error ± 0·0092cc.

I now sought to compare our tin process with the "bichrome" and "permanganate."

Permanganate Process.

For the standard permanganate solution 1grm. was dissolved in 1000cc. water, and the ferric chloride was reduced by 0·8grm. zinc dust in a flask provided with a narrow exit tube, and containing 5cc. HCl and 10cc. water. After complete solution, 50cc. boiled and cooled distilled water were added.

Blank Test:—

0·8grm. zinc consumed 0·60cc. } Mean, 0·565cc.
" " " 0·53

Fe_2Cl_6 Solution.	$KMnO_4$ Consumed.	
1·0cc.	4·85cc.	Mean, 4·835cc.
1·0	4·85	
1·0	4·82	
1·0	4·82	
1·9	8·45	
0·6	3·20	
1·2	5·80	
0·3	1·70	
0·9	4·45	
0·5	2·70	
1·6	7·20	
2·0	9·00	

Mean experimental error ± 0·0294cc.

Bichrome Process.

Half decinormal solution of bichromate of potash was used, and zinc to reduce the iron. Acid, etc., same as with the permanganate process.

Blank experiment showed mere trace of iron.

Fe_2Cl_6 Solution.	$K_2Cr_2O_7$ Consumed.
0·6cc.	1·20cc.
1·1	3·30
1·7	4·70
0·4	1·10
0·8	2·30
1·9	5·40
2·4	6·50
1·5	4·10
1·3	3·50

Mean experimental error ± 0·0548cc.

Another series was made with "bichrome," but $SnCl_2$ was the reducing agent.

Mean of 4 experiments with 1cc. Fe_2Cl_6, gave 2·55cc.

Fe_2Cl_6 Solution.	$K_2Cr_2O_7$ Consumed.
2·1cc.	5·05cc.
0·9	2·30
0·5	1·35
0·7	1·75
1·1	3·50
0·3	0·95
1·1	2·80
1·8	4·55

Mean experimental error ± 0·0354cc.

I next tried those three methods with the actual char, but before describing them, allow me to say a word about the state of oxidation of iron in chars. It exists, probably, in both the ferrous and ferric conditions; even metallic iron is met with in new char. But it appears impossible to determine their respective amounts, owing to the reducing action of the carbon present. When a char is boiled in dilute hydrochloric acid, all the iron is found as FeO, but Fe_2O_3 can be detected, if it is dissolved in the cold; even under these conditions the carbon still exerts its action. For example: The carbon was separated by means of acid, from both a new and a stock char, carefully washed, and then simply mixed with 1cc. of standard solution of iron, 5cc. HCl and 10cc. H_2O, allowed to digest for an hour in the cold, when over 80 per cent. of iron with the former, and about 60 per cent. with the latter, were found to be reduced. However, we generally report it in the trade as Fe_2O_3.

We now proceed to detail the char experiments. The samples were passed through a "60" mesh sieve, and 2grms. weighed off in a platinum capsule, and thoroughly ignited, then dissolved in 5cc. HCl and 10cc. H_2O. Two chars were used throughout, one being a new, the other a stock char, except in the case of the bichrome "new char" tests, when another sample had to be used, owing to my supply having failed. In the case of the bichrome process, I had to abandon the use of zinc as a reducing agent, as the results came out too low—*e.g.*, the new char, containing about 0·2 per cent. Fe_2O_3, scarcely gave a reaction with potassium ferricyanide. When, however, $SnCl_2$ was substituted, better results were obtained, though still on the low side.

Bichrome Process.

New Char.

Consumed	0·70cc.
"	0·50
"	0·40
"	0·70
Mean	0·575cc.

=0·113 % Fe_2O_3. (Tin process, 0·161%.)

Mean experimental error ± 0·125cc., equal to 0·024% Fe_2O_3

Stock Char.

Consumed	4·2cc.
"	4·0
"	3·9
"	3·95
Mean	4·013cc.

=0·787 % Fe_2O_3.

Mean experimental error ± 0·074cc., equal to 0·0135% Fe_2O_3

Permanganate Process.

Blank Test.—Mean of 2 experiments, consumed 0·565cc.

New Char.

Consumed	2·1cc.
"	2·3
"	2·0
"	2·0
Mean	2·1cc.

= 0·180% Fe_2O_3.

Mean experimental error ± 0·1cc. = 0·0117% Fe_2O_3

Stock Char.

Consumed	7·8cc.
"	7·7
"	7·5
"	7·8
Mean	7·7cc.

= 0·835% Fe_2O_3.

Mean experimental error ± 0·1cc. = 0·0117% Fe_2O_3

I may here parenthetically remark that Tucker, in his "Manual of Sugar Analysis," recommends the filtrate from the carbon to be titrated, but the organic matters in solution cause too high results. The above new char, for example, instead of yielding 0·18 per cent., gave 0·33 per cent, and the "stock" char gave 0·89 per cent. instead of 0·835 per cent.

Tin Process.

The iron should be fully oxidised, with 5 drops of peroxide of hydrogen (20 vol.) and boiled gently for three minutes, to expel the excess. This causes no loss through volatilisation. I prefer hydroxyl to potassium chlorate, because one can add a definite quantity without weighing, and an excess appears to be more readily expelled.

Standard Tin Solution.—Mean of 5 experiments, 2·89cc. = 1cc. standard Fe.

New Char.

Consumed	1·35cc.
"	1·35
"	1·28
"	1·30
Mean	1·32cc.

= 0·228 % Fe_2O_3

Mean experimental error ± 0·03cc. = 0·0059% Fe_2O_3

Stock Char.

Consumed	1·7cc.
"	1·8
"	1·8
"	1·8
Mean	1·775cc.
	= 0·826 % Fe_2O_3.

Mean experimental error ± 0·037cc. = 0·0065 % Fe_2O_3

The end reaction is not quite so distinct as with the pure Fe_2Cl_6 solution, owing to the presence of a little insoluble matter which floats in the liquid. This may be obviated by filtration, but at the same time avoiding any unnecessary excess of wash water, which would of course interfere with the reaction.

In conclusion, I confidently recommend the tin process in preference to either the permanganate or bichrome. For both, with the pure Fe_2Cl_6 solution and the chars, we find the experimental errors to be less. Besides being the most accurate, it is also the most speedy—five minutes sufficing for a single estimation.

Allow me to take the opportunity of acknowledging my best thanks for the time afforded by my employers, John Walker & Co., for carrying out the above experiments.

NOTE ON THE DETERMINATION OF AMMONIA IN COMMERCIAL PRODUCTS.

BY J. M. MILNE, PH.D., F.I.C.

Two methods are in general use for the determination of ammonia—viz., by conversion into the double chloride of ammonium and platinum—a process too well known to require description, or by previous liberation of the ammonia, either by combustion with soda-lime or distillation with strong solution of caustic soda, and absorption in an excess of hydrochloric acid, with subsequent conversion into the platinum salt on the one hand, or absorption in a measured excess of standard sulphuric acid and reverse titration with standard alkali.

The platinum method, although an elegant and accurate one where nearly pure salts have to be dealt with, has one or two drawbacks for commercial work. It is expensive, and occupies a good deal of time. As regards the other method, anyone who has tried the soda-lime process in the case of ammonia salts, even with previous addition of starch or sugar, will have realised the annoyances incidental to it. Distillation with caustic soda is also troublesome, from the tendency of a strong alkaline solution to froth up and bump when boiled, with possible projection of a little of it into the condensing arrangement, to the detriment of the determination. Some time ago a German committee was appointed to report on the methods in use for the analysis of phosphates, manures, etc., and to make suggestions as to the adoption of uniform methods. With regard to the determination of ready-formed ammonia in manures and salts, this committee recommended the liberation of the ammonia by boiling with magnesia instead of caustic soda, and absorption in a measured excess of standard sulphuric acid. One great advantage of this modification is that the contents of the distilling flask boil quite quietly, and can be brought nearly to dryness without spirting, if the gas flame is properly regulated. As I have used the magnesia method for some time with very satisfactory results, and the apparatus is very simple, I thought it might be of interest to some of you to see it in actual operation. An 8 or 10oz. wide-mouth flask is fitted with an indiarubber cork, pierced with two holes, through one of which passes a small funnel with a tap, and through the other a somewhat wide exit tube. The latter is connected with a short inverted condenser, the lower end of which is tightly fitted to the neck of a nitrogen bulb of the new form, in which 20cc. of normal sulphuric acid have been previously placed. A weighed quantity of the sample is placed in the flask, together with 2grms. of magnesia, and about 60cc. of water, and the mixture kept gently boiling by means of a rose-burner. When the contents of the flask are nearly dry, the flame is removed, about 10cc. of water run in from the funnel, and the boiling continued. This operation is repeated two or three times. Finally the nitrogen bulb is connected with a small aspirator, and a gentle current of air drawn through the whole apparatus for a few minutes, in order to ensure complete absorption of all the ammonia. The exit tube is then disconnected from the condenser, and the latter rinsed, into the bulb, with a little water, a few drops of cochineal added, and the excess of normal acid determined with fifth-normal soda.

In using the apparatus, the committee recommend the following precautions to be observed:—(1) that the steam containing the ammonia be thoroughly condensed as it passes over; (2) that the end of the condenser tube does not dip beneath the surface of the sulphuric acid in the bulb flask; and (3) that complete absorption of the ammonia is ensured by attaching a small U-tube containing a little of the standard acid to the exit tube of the flask.

ORTHO-CHROMATIC PHOTOGRAPHY.

BY C. H. BOTHAMLEY, F.I.C., F.C.S.,

Assistant Lecturer on Chemistry, and Lecturer on Photography in the Yorkshire College, Leeds.

It is well known that the ordinary photographic processes fail to give pictures with true values, or, in other words, they fail to render coloured objects with their proper degrees of relative brightness. Yellow, orange, and green objects, which are bright to the eye, are dark in a photograph, whilst blue, purple, and violet, which are comparatively dark to the eye, are bright in a photograph. Photographic effect is not coincident with optical effect.

In order to ascertain the cause of these differences it is necessary to separate ordinary white light into its component rays, and to measure the optical and photographic effects of the separated rays. This is done most conveniently by means of the spectrum, and the effects produced by different parts of the spectrum are best expressed in the form of a curve, the base line of which represents the spectrum, whilst the ordinates or heights of the curve above the base line at any given points represent the intensity of the action at those points. The abscissæ, or points marked off along the base line, represent the principal Fraunhofer lines.

The optical effect or relative luminosity of different parts of the spectrum has been estimated by several observers, notably by Vierordt, and more recently by an improved method by Abney and Festing.[*] The relative luminosity of the different parts varies with the nature of the source of light, with the absolute brightness of the light, and with different observers; but the general result is that the maximum luminosity is in the yellow, not very far from the line D. The brightness diminishes somewhat rapidly in the green and then very gradually in the blue and violet, the more refrangible part of the visible spectrum terminating close to the line H. On the less refrangible side of D the luminosity falls off gradually but rapidly through the orange and orange red to the line A at the termination of the red. (Fig. 1, No. 3.)

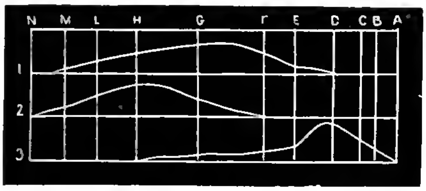

Fig. 1.

When the spectrum falls upon an ordinary gelatino-bromide plate—that is, a glass plate coated with a thin dry film of an emulsion of silver bromide in gelatin—it is found that the maximum photographic effect is produced by the blue about midway between F and G. A considerable amount of action is exerted by the violet, and the invisible rays beyond the violet, and on the less refrangible side of the maximum the action falls off rapidly, becoming very small in the green and ceasing altogether before it reaches the line D. By suitable treatment, however, the sensitiveness of the gelatino-bromide can be increased so that if the exposure is sufficiently long a sensible though slight amount of action is exerted by the yellow, orange, and even by the orange red. (Fig. 1, No. 1.) When silver gelatino-chloride is examined in the same way the maximum effect is produced close to the line H, and the action diminishes gradually but rapidly on either side, ceasing altogether in the green. (Fig. 1, No. 2.)

From these results it is evident that the rays which produce the greatest effect on the eye, the yellow, green, and orange, have little or no action on an ordinary photographic plate, whilst blue and violet rays, which have comparatively little action on the eye, produce the greatest effect on the plate. It follows that in order to photograph coloured objects in correct gradations the character of the photographic plate must be so altered that the sensitiveness to yellow, orange, and green is very considerably increased, whilst the sensitiveness to blue and violet is much diminished. According to Dr. Eder,[†] the orange near C and the full blue near F should exert about the same amount of action, whilst the effect of the yellow near D should be eight times, that of the yellowish green near D ten times, and that of the green near E three times, the effect of the blue. Violet, on the other hand, should exert only about one-tenth as much action as the blue. The term "Ortho-chromatic Photography" is used to denote the photographic representation of all classes of coloured objects with their proper degrees of relative brightness, or, to use the artistic term, with their proper "values." The power of photographing rays of low refrangibility is not only valuable from a pictorial point of view, but is of the greatest importance in spectrum photography.

In 1873 Dr. Hermann W. Vogel[‡] discovered that if certain dyes, such as corallin or aniline greens, are added to a sensitive dry collodion film, the film becomes sensitive to yellow or greenish yellow, and the rays to which the plates become sensitive correspond closely, but do not coincide, with the rays which are absorbed by the dye. Substances which produce this result were classified by Vogel as "optical sensitisers," on the ground that their action depends upon their power of absorbing light rays. These observations were confirmed by Carey Lea, Waterhouse, Becquerel, Abney and others, and on the Continent the principle was applied with considerable success to the reproduction of paintings. Cros and Ducos du Hauron[§] also made it the basis of an indirect process of photography in colour through the medium of chromo-lithography.

Shortly afterwards, however, the modern dry plate or gelatino-bromide process was introduced, and gradually displaced the older collodion processes. The first attempts to employ dyes with gelatino-bromide plates gave unsatisfactory results, but in 1882—83 Attout and Clayton, commonly known as Tailfer and Clayton, took out a patent[‖] in France and England for the application of eosin in conjunction with an alkali to gelatino-bromide plates, the term eosin being understood to include all the dyes belonging to the eosin group. By this treatment the plates, which are sold under the name of "Isochromatic" plates, are made very sensitive to the greenish yellow rays. Schumann confirmed the advantages resulting from the use of eosin, and Vogel introduced plates stained with a dye to which he gave the name "Azalin," but which is understood to be a mixture of cyanin, or quinoline blue, with quinoline red.

The question has been made the subject of a long and careful series of experiments by Dr. Josef Maria Eder, of Vienna, who has investigated the effect produced by more than 160 different dyes under a variety of conditions.

Two methods are employed for impregnating the silver gelatino-bromide with the dye. In the first the dye is added to the melted emulsion before coating the plates; in the second the coated and dried plates are steeped for a few minutes in a neutral or ammoniacal solution of the dye in water or alcohol. The proper regulation of the proportion of dye is found to be a point of the greatest importance. If too little dye is used the maximum effect is not obtained, whilst if the quantity of dye exceeds the proper amount its effect is likewise diminished. When the dye is added to the emulsion, 2—4 milligrams per 100cc. of melted emulsion is found to be sufficient, whilst for bathing the dry plates a solution of the dye in 20,000 or 30,000 parts of water may be used. The higher the tinctorial power of the dye, the smaller the amount that is required.

Eder[¶] found that comparatively very few dyes have any effect in increasing the sensitiveness of gelatino-bromide plates to the less refrangible rays, and in the majority of cases in which an effect is observed it is but small, and can only be recognised when the exposure is prolonged and the dye is present in the proper proportion. It is necessary to dis-

tinguish between the effect of a dye on the general sensitiveness of a plate to light as a whole, and on its relative sensitiveness to particular rays. The majority of dyes render the plates less sensitive to ultra-violet, violet, and, in several cases, blue rays, and thus diminish their general sensitiveness to one-fifth, or even one-tenth, of its original value, whilst at the same time the relative sensitiveness to particular says, such a yellow, orange, or green, may be increased many times.[*] The results are represented in the form of curves.

Violet dyes, such as Hofmann's violet, gentian violet, methyl violet, acid violet, diminish the general sensitiveness, mainly by making the plate much less sensitive to ultra violet rays. At the same time the sensitiveness to green, yellow, and orange is considerably increased, the maximum effect being observed between D and C. (Fig. 2, No. 1.)

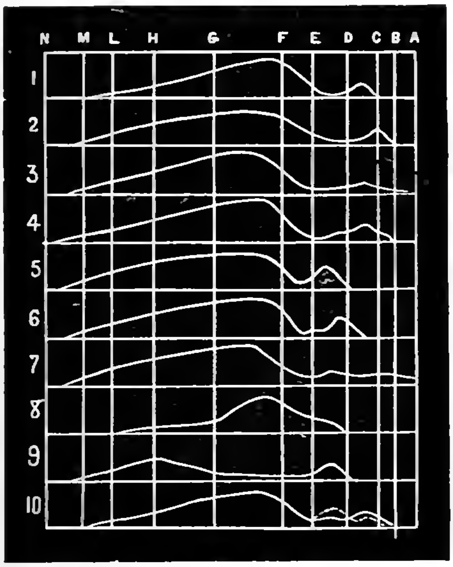

Fig. 2.

(1) Violets. (2) Greens. (3) Iodine Green. (4) Cyanin. (5) Eosin. (6) Rose Bengal + Ammonia. (7) Cœrulein. (8) Chrysaniline. (9) Eosin and Silver Chloride, (10) Eosin + Cyanin.

Green dyes, such as acid green, benzaldehyde green, ethyl green, methyl green, and their varieties, have very little sensitising action, and their effect can only be observed with prolonged exposure and brilliant illumination, great attention being paid to the proper regulation of the proportion of dye. Under favourable conditions the plate is made slightly sensitive to yellow, orange and red, the point of maximum effect being situated close to the line C. (Fig. 2, No. 2.) Iodine green is worthy of notice, since its sensitising action, although feeble, extends to the extreme red. (Fig. 2, No. 3.) In this respect, however, it is far inferior to certain dyes which were investigated subsequently.

Cyanin, or quinoline blue, confers on silver gelatino-bromide a high degree of sensitiveness to orange and red, a fact which was discovered simultaneously by Eder and Schumann. Ordinary or iodo-cyanin gives the best results, but all the commercial varieties behave similarly. The general sensitiveness of the plate is considerably diminished, but the sensitiveness to yellow, orange, and orange-red becomes comparatively great, the maximum effect being observed between D and C. The sensitiveness to orange is more than a hundred times as great as that of an undyed plate. If ammonia is added together with the cyanin, the effect of the latter is still more marked. (Fig. 2, No. 4.)

Eosin, and the dyes belonging to the same group, exert a considerable sensitising action for yellowish green and yellow, the maximum action being nearer D the bluer the shade of the dye. In the case of eosin (tetrabromfluorescein) itself the maximum is between E and D; in the case of rose Bengal, the sodium salt of tetra-iodo-dichlorofluorescein, the maximum is a little to the more refrangible side of D. Simultaneous addition of ammonia increases the effect of these dyes.

Naphthol blue[†] (which is not the same as indophenol blue), and the seemingly identical neutral blue of the Frankfort Anilin Farbenfabrik, have the remarkable property of rendering a plate sensitive without interruption to the whole length of the spectrum, from wave-length 3600 to wave-length 7600. The first maximum is at the usual place in the blue, about midway between G and F, and there is a second smaller maximum close to C. In order to apply these dyes to the plates, the latter are steeped in a solution of 1 part of the dye in 3000 to 10,000 parts of water, to which has been added 1—2 per cent. of ammonia. Notwithstanding the behaviour of such plates to the spectrum, no satisfactory results were obtained when these dyes were applied to the photographing of paintings.

Cœrulein,[‡] used in the form of cœrulein S, which is a compound of cœrulein with sodium hydrogen sulphite, excels even naphthol blue in its power of sensitising for the less refrangible rays. It has the additional advantage that it does not make the plates so liable to fog under the action of the developer, and thus gives clearer and better negatives.

Gelatino-bromide plates stained with any of the last three dyes excel all known photographic preparations in their qualitative sensitiveness to rays of different wave-lengths, the sensitiveness extending from the ultra-violet to at least a short distance into the infra-red.

Chlorophyll, which was found by Ives[§] to give excellent results with collodio-bromide plates, gives very uncertain results with gelatin plates, but some recent experiments by Dr. Maddox[‖] indicate that this point is worthy of further investigation.

Rosaniline, Magdala red, Coupier's blue, many indulin dyes and others, sensitise for the less refrangible rays, but their action is comparatively feeble. Chrysaniline is a good sensitiser for green. (Fig. 2, No. 8.) Other dyes, such as corallin, acid magenta and resorcinol blue, do not increase the sensitiveness to yellow, etc., but render the plates much less sensitive to the ultra-violet and violet rays, and thus increase the *relative* sensitiveness to blue, whilst they greatly reduce the general sensitiveness of the plates. Chrysaniline likewise shows this action in a very marked degree.

When the silver gelatino-bromide is not pure, but, as frequently happens, contains a certain proportion of silver iodide, the phenomena are of the same order, though not always of the same magnitude. The presence of silver iodide does not appreciably affect the sensitising action of the dyes, provided that the proportion of iodide does not exceed about 3 per cent., but if the amount exceeds 10 per cent. the sensitising action is diminished.

The effect of dyes on silver gelatino-chloride is of the same general character as their effect on the bromide. In the case of a gelatino-chloride plate

stained with eosin, the sensitiveness to yellowish green is so much increased, whilst that to ultra-violet and violet is so much reduced that the former becomes equal to the latter. (Fig. 2, No. 9.)

In almost all cases, the curve representing the effect of the spectrum shows two maxima separated by a minimum which is usually in the green or yellowish green. The first maximum is in the blue, and this part of the curve corresponds with the ordinary action of the blue, violet, and ultra-violet rays on an undyed plate. The second and smaller maximum is in the less refrangible half of the spectrum, and varies in position and magnitude according to the nature of the dye. When the exposure is very brief, the minimum portion of the curve disappears, and the action is represented by two detached curves, one in the more refrangible and the other in the less refrangible half of the spectrum, separated by a region in which there is no perceptible action.

When ammonia is added simultaneously with the dye, the sensitising action is greater, and extends further on each side of the maximum. In none of Eder's experiments, however, was the plate as sensitive to the less refrangible rays of the solar spectrum as to the blue and violet.

With a large number of dyes, the negatives are much more intense with the dyed plates than with the undyed plates. The dyes, in fact, behave in much the same way as an excess of alkaline bromide in the emulsion, and give stronger and denser negatives at the cost of reduced sensitiveness.

The fact that with different dyes the second maximum is situated at different points in the less refrangible region, at once leads to the supposition that by mixing the dyes it might be possible to make the plates uniformly sensitive to this region of the spectrum. This conclusion, however, is not completely supported by experiment. It is found that one dye interferes with the action of another. With a mixture of eosin and cyanin, for example, if the former is in excess, the sensitiveness to orange is less than with the same proportion of cyanin alone; and if the latter is in excess, the sensitiveness to yellowish green is less than with the same proportion of eosin alone. The action of the spectrum on plates dyed with such mixtures is shown by curve 10, Fig. 2, in which the dotted curve represents the result with eosin in the greater proportion, and the unbroken curve the result when cyanin is in the greater proportion.

The results of Vogel's and of Eder's investigations have been extensively applied on the Continent to the preparation of gelatino-bromide plates sensitive to yellow, green, and orange, for the purpose of photographing paintings and coloured objects generally. The spectrum experiments show that although by treating the plates with various dyes their sensitiveness to the less refrangible rays is very greatly increased, the sensitiveness to blue and violet still remains much greater, and therefore, in order to obtain correct gradations in the photograph, it is necessary to diminish the intensity of the blue and violet rays before they reach the plate. This is done by interposing a transparent yellow screen between the object and the lens. Although many successful results have been obtained, the reports of different experimenters as to the value of the processes are conflicting. An additional difficulty is introduced by the fact that the same dye is met with under a large number of different trade names, and in some cases different dyes have the same or very similar names. Moreover, commercial dyes vary considerably in purity, and therefore in the effects which they produce. Vogel states,* for example, that eosins from different sources give very different results; rose Bengal of French manufacture is a very good sensitiser, whilst that from a Belgian source is very much inferior in its action.

The scientific interest of this question, and its great importance from a photographic point of view, led me to undertake a series of experiments, the results of which I have the honour of bringing before the Society in this paper. Eder's researches show that the fluorescein dyes and cyanin exert the greatest sensitising action, and this has been confirmed by Mallman and Scolik and others, who have actually applied these dyes to ordinary photographic purposes. I therefore confined my attention almost exclusively to these dyes, and my experiments may be classified under three heads—(1) a comparative examination of commercial samples of the fluorescein dyes; (2) the action of the prismatic spectrum on plates stained with these dyes; (3) the application of such plates to the photography of flowers, paintings, and other coloured objects.

Comparative Examination of Dyes.—The principal dyes derived from fluorescein are eosin, which is tetrabromofluorescein: phloxin, which is dichloro-tetrabromofluorescein; erythrosin, or tetra-iodofluorescein; and rose Bengal, or dichloro-tetra-iodofluorescein. All these compounds are insoluble in water, but they are usually met with in the form of sodium or potassium salts, which are readily soluble in water. Very many different samples of these dyes are put into the market by different manufacturers, and are distinguished by letters, such as eosin A, eosin JJ, erythrosin B, erythrosin RE. When used for dyeing they produce somewhat different shades of colour. They differ considerably in the proportion of water which they contain. One sample of erythrosin, for example, lost 8·8 per cent. when dried at 115—120°, whilst another sample lost 12·5 per cent.; one sample of rose Bengal, under similar conditions, lost 17·4 per cent., whilst another lost 18·0 per cent. The eosins show a strong yellowish green fluorescence; the fluorescence of phloxin is less marked, and is of a deeper tint; erythrosin and rose Bengal are not fluorescent at all. The various samples were compared by examining the absorption spectra of their aqueous solutions. This method of examination gives no exact information as to the magnitude and position of the sensitising effect of the dyes when they are applied to a gelatino-bromide plate, where they are in the dry condition and are intimately associated with gelatin and silver bromide; but it serves, in a great measure, to determine the identity of different samples, and affords information as to whether a given sample is a mixture or consists of a single compound only.

The spectra were examined by means of a Steinheil spectroscope with two large flint glass prisms, the measurements being made by means of a reflected photographic scale, which was so adjusted that the sodium line coincided with division 100. The dyes, for which I am indebted to Prof. J. J. Hummel, were dissolved in 10,000 parts of water, and the layer of liquid examined was 18·3mm. in thickness. The source of light was a Peebles governor burner No. 5, at a distance of about 4 inches from the tube containing the liquid. Fifteen samples of dyes were examined, and the position of the absorption band is given in the following table:—

Dye (1 : 10,000).	Absorption Band D=100
1. Eosin A (Badische-Anilin und Soda Fabrik) ..	140—285
2. Eosin JJ (Society of Chemical Industry)	141—285
3. Eosin SGF (L. Casella and Co.)	140—290
4. Eosin VE (Poirrier and Co.)	140—275
5. Phloxin (P. Monnet)	122—235

---

* Photographic News, 1886, 803.

Dye (1: 10,000).	Absorption Band D = 100
6. Phloxin (Meister Lucius and Bruning)	128–255
7. Erythrosin B (Casella and Co.)	130–265
8. Erythrosin I (B. A. S. F.)	133–250
9. Erythrosin (Poirrier and Co.)	135–250
10. Erythrosin BE (Poirrier and Co.)	121–210
11. Erythrosin R E (Poirrier and Co.)	131–250
12. Erythrosin extra (Meister Lucius and Bruning)	133–250
13. Rose Bengal B (Meister Lucius and Bruning)	120–215
14. Rose Bengal (P. Monnet)	119–215
15. Cyanin	60–190

Since the examination was purely comparative, it was not necessary to calculate the wave-lengths of the bands, but the following reference lines will enable this to be done:—

Li α = 47; Sr α = 85—89; D = 100; Ba γ = 132; Tl α = 152·5; Ba α = 165; Ba β = 179; Mg* = 167—169; 191—193; 265; Sr δ 268.

The absorption spectra of the four eosins are evidently identical, and they were, in fact, found to exert equal effects when applied to the plates. The divergences in the extension of the band into the violet may be ascribed to differences in the proportion of water in the different samples, and partly to the difficulty of determining the exact point at which the band ceases, a difficulty which is increased by the very nebulous character of this end of the band. The differences may also be partly due to the fact that some are sodium salts, whilst others contain potassium. The two samples of phloxin are not identical, and it is not at all improbable that both are mixtures. Erythrosin B is not identical with the other erythrosins. It shows a decided fluorescence, and its absorption spectrum and behaviour with silver nitrate indicate that it is a mixture of eosin with erythrosin or rose Bengal, the former being probably present in the greater proportion. The spectrum of erythrosin BE shows that it is really a rose Bengal, and this conclusion is confirmed by the character of its sensitising action on gelatino-bromide plates. The remaining four samples of erythrosin, Nos. 8, 9, 11, 12, are identical so far as their absorption spectra are concerned, and Nos. 8, 9, and 12 exert a practically identical sensitising effect. The two samples of rose Bengal are likewise identical. It is worthy of note that the addition of ammonia has no effect on any of these absorption spectra.

The relation between the optical properties of the eosin dyes and their molecular weights is of considerable interest. The intensity of the fluorescence rapidly diminishes, and the tint of the dye becomes bluer as the molecular weight increases. Fluorescein itself gives a greenish-yellow solution, and its fluorescence is extremely brilliant. Eosin shows a strong fluorescence, whilst erythrosin and rose Bengal are not fluorescent, and the colour of the latter has a decidedly blue shade. Further, the absorption band becomes narrower, more intense, and less refrangible as the molecular weight increases. This is clearly shown by the measurements given in the table.

Effect of the Prismatic Spectrum on Dyed Plates.—The dyes were applied by the bath process exclusively, the plates used being those known as the Paget Prize Plates XXX. They are very sensitive, although not ranking with the most sensitive plates that are made.

In preparing the plates stock solutions were made (1) by dissolving one part of dye in 1000 parts of water, and (2) by diluting strong ammonia to ten times its volume.

When the dyes were applied without ammonia the plates were soaked in water for two or three minutes, and then, after slight draining, immersed for two minutes in a bath prepared by mixing *dye solution* (1 : 1000) one part, *water* nine parts. They were then allowed to drain with their edges on blotting paper, and were dried in complete darkness.

When ammonia and a dye were employed simultaneously the plates were soaked for two or three minutes in dilute ammonia, prepared by mixing one part of strong ammonia with 99 parts of water, and were then immersed for two minutes in

Dye solution (1 : 1000)	1 part,
Ammonia (1 : 10)	1 ,,
Water	8 parts,

drained and dried in the dark. Whilst the plates are soaking the dishes containing them should be rocked gently in order to promote regular action and uniform staining. It will be observed that in both cases the sensitising bath contains 1 part of dye in 10,000.

In the case of cyanin the solution was prepared according to Schumann's formula.† One part of iodocyanin is dissolved in 500 parts of absolute alcohol, and the bath is made up as follows:—

Cyanin solution (1 : 500)	10 parts.
Strong ammonia	2–4 ,,
Absolute alcohol	10 ,,
Water	200 ,,

The plates are soaked in dilute ammonia as above, immersed in the cyanin bath for two minutes, and dried in the dark. Plates thus treated must be used immediately after preparation, since they will not keep in good order for more than five or six days.

After exposure, the plates were developed with a solution which contained in each fluid ounce 1 grain of pyrogallol, 3 grains of ammonium bromide, and 6 minims of ammonia 0·880, and were fixed and washed in the usual manner.

In these experiments I employed, like previous observers, the prismatic spectrum. Such a spectrum is, however, as is well known, of an abnormal character, since the rays are not separated in proportion to their wave-lengths, but the less refrangible rays are crowded together, whilst the more refrangible are more widely separated than they ought to be. In a diffraction spectrum, on the contrary, the distances between the rays are proportional to their wave-lengths. If the length of the visible spectrum is divided into 1000 equal parts, the distance from A to D in the prismatic spectrum is 220 divisions, and from D to H 780 divisions, whilst in the normal or diffraction spectrum the distance between A and D is 468 divisions, and from D to H 532 divisions. It is obvious, therefore, that when a prismatic spectrum is employed, the relative effect of the less refrangible rays will be magnified, whilst that of the more refrangible rays will be diminished,‡ and consequently it is much to be desired that in experiments of this kind a diffraction spectrum should be used when possible. In these experiments I have endeavoured to select a source of light of such a character as to compensate, as far as possible, for the defects of the spectrum.

The spectroscope employed was kindly placed at my disposal by Professor Birch, by whom it had been arranged for photographic work. It is one of Hilger's construction, with an adjustable slit and one carbon bisulphide prism. The ordinary objective of the observing telescope was replaced by a lens with a focal distance of 21 inches. The eye piece was removed and the end of the telescope fitted into an ordinary camera, the back of which was provided with a horizontal swing, so that the whole length of the spectrum could be obtained in focus at once. The slit was used with an aperture of $\frac{1}{50}$ of an inch, and care was

---

* Bands in the spectrum of burning magnesium.

† Year-book of Photography, 1887, p. 191.

‡ See Draper, Philosophical Magazine, 1872.

taken to protect the carbon bisulphide from changes of temperature during the exposures. It is scarcely necessary to point out that the carbon bisulphide used in experiments of this kind must be perfectly colourless.

Previous investigators have employed the solar spectrum, but the intensity of sunlight is so variable, especially in this climate, that it is practically impossible to obtain comparable exposures throughout a long series of observations. Moreover, sunlight not only varies in intensity, but also in character—that is, in the relative proportions of rays of high refrangibility and low refrangibility which it contains.[*] In order to obtain comparable results, I employed as a source of light burning magnesium ribbon, which was paid out at the rate of 2 feet 4 inches per minute, by means of an arrangement of clock-work. By burning a sufficient length of ribbon at a uniform rate the effects of inequalities are eliminated, and a unit of exposure sufficiently constant for all practical purposes is readily obtained. Moreover, as Bunsen and Roscoe pointed out several years ago, the light from burning magnesium is far superior to sunlight in its proportion of rays of high refrangibility, which are the chemically active rays so far as concerns the ordinary silver salts. The luminosity or optical activity of the sun's light at a certain zenith distance is 524·7 times as great as that of burning magnesium ribbon, whilst its chemical activity, which in this case depends on the proportion of rays of high refrangibility, is only 36·6 times as great.[†] By using a source of light containing such a very large proportion of rays of high refrangibility, the defects of the prismatic spectrum are to a certain extent neutralised, and the effects observed with a prismatic spectrum of the light from burning magnesium will approximate more or less closely to the effects produced by a diffraction spectrum of sunlight. The visible spectrum obtained was about 75mm. in length, the blue and violet regions being very bright. The exposure for each plate with the aperture of slit given above, was one minute, which corresponds with a length of ribbon of 2 feet 4 inches, or about 70 centimetres.

The dyes actually used as sensitisers were:—Eosin A; eosin SGF; eosin YE; erythrosin I; erythrosin extra; erythrosin (Porrier); erythrosin BE; phloxin (P. Monnet); phloxin (M, L and B); rose Bengal (P. Monnet); rose Bengal B; cyanin; crystal violet; ethyl purple; night blue (B.A.S.F.); violet 5BO. Unstained plates were exposed under similar conditions.

Crystal violet, night blue, ethyl purple and violet 5BO, although they completely absorb the orange, yellow and green, exert very little sensitising action on the plates, a result which confirms Eder's experiments with these dyes.

The results obtained with eosin and its allies and cyanin are represented by the curves in Fig. 3. The reference lines are D, B,[‡] and two other bands which are observed in the spectrum of burning magnesium. That next to B is a broad band composed of 5 or 6 lines,[§] and is situated very near F; the other is a much narrower band, close to the blue strontium line. The curves are not strictly comparable one with another. Each curve must be regarded separately and represents the relative actions of different parts of the spectrum. They are constructed from observations during the development of the plates and from comparisons of the densities of different parts of each negative. Each curve is the mean of several experiments. No increase in accuracy is gained by making elaborate measurements of the densities of the negatives, since the relative densities of different parts of the same negative vary with the time of exposure, and also with the time during which the developer has been allowed to act; moreover, the results will vary slightly with silver gelatino-bromide prepared in different ways.

In their general character my results agree with those of Eder, but there are some important differences of degree. The sensitiveness to ultra-violet and violet is somewhat diminished, but the sensitiveness to the less refrangible rays is very largely increased. Each curve has two maxima, separated by a region of minimum action. Eosin, in aqueous solution, exerts a comparatively slight, although distinct, sensitising action; with phloxin the effect is somewhat more strongly marked, but the results with this dye are not very definite owing to the uncertainty which exists as to the real nature of the substances sold commercially as phloxin. Eder found phloxin to be inferior to eosin as a sensitising agent. Erythrosin produces by far the greatest sensitising effect of the dyes of this group, whilst rose Bengal is inferior to erythrosin, but is far superior to eosin.

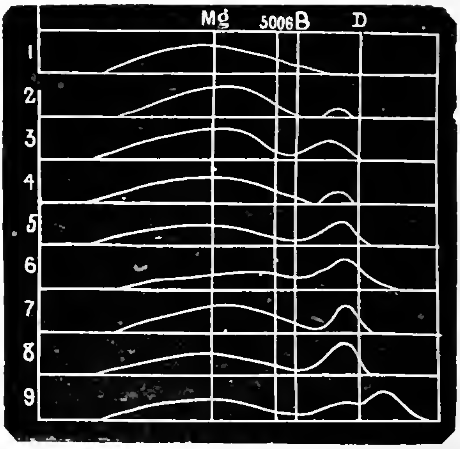

FIG. 3.

(1) Ordinary plate, (2) Aqueous Eosin, (3) Ammoniacal Eosin, (4) Aqueous Phloxin, (5) Aqueous Erythrosin, (6) Ammoniacal Erythrosin, (7) Aqueous Rose Bengal, (8) Ammoniacal Rose Bengal, (9) Ammoniacal Cyanin.

Cyanin differs from eosin, etc., in that it sensitises for yellow and orange and orange-red instead of for greenish yellow and yellow. It will be observed that with cyanin the second part of the curve shows two maxima, as Eder and Schumann have previously observed.

The simultaneous presence of ammonia increases the magnitude of the sensitising action, and by causing this action to extend to a greater distance on either side of the maximum tends to obliterate the region of minimum action. In the case of some of the plates treated with ammoniacal erythrosin it is even somewhat difficult to recognise the existence of the minimum at all. The difference between the action of aqueous and ammoniacal solutions is greatest in the case of eosin, but even in presence of ammonia this dye remains inferior as a sensitiser to aqueous erythrosin. Erythrosin in presence of ammonia exerts the greatest sensitising action of any dye with which I am acquainted.

The most remarkable result of these experiments, however, is that plates dyed with aqueous or ammoniacal erythrosin, ammoniacal rose Bengal, or ammo-

niacal cyanin, are *more sensitive to the less refrangible rays of the spectrum (yellow, greenish yellow, or orange) than to the blue and violet*, and this even with a source of light which is extremely rich in chemically active rays of high refrangibility. Eder[*] found that silver gelatino chloride stained with eosin was as sensitive to yellowish green as to violet, and Vogel[†] states that the commercial Clayton and Attout plates are twice as sensitive to spectrum yellow as to the blue, but with these exceptions I am not acquainted with any published record of gelatin plates which are more sensitive to rays of low refrangibility than to those of high refrangibility. When burning magnesium is the source of light, plates dyed with aqueous erythrosin are about half as sensitive again to the yellow of the spectrum as to any part of the blue or violet; plates dyed with ammoniacal rose Bengal show a similar relative sensitiveness; plates dyed with ammoniacal erythrosin are somewhat more than twice as sensitive to the yellow as to any part of the blue or violet. Plates dyed with cyanin according to Schumann's formula are about half as sensitive again to orange as to blue or violet. With sunlight, which is relatively poorer in blue and violet, the relative sensitiveness to yellow would be still greater. Doubtless, too, the results will vary to a certain extent with different batches of plates.

The differences between my results and those obtained by Eder are probably due (1) to the use of plates which were not prepared in the same manner; (2) to the fact that in many of Eder's experiments the dyes were added to the emulsion, whilst in mine they were applied exclusively in the form of a bath; (3) to the fact that Eder's bath solutions were not so concentrated as those which I have employed. Comparative experiments showed that Eder's formula for the preparation of the dyed plates for general photographic purposes contained too small a proportion of the dye to give the maximum attainable result.

Why do these dyes produce such a remarkable effect when mixed with the silver bromide?

Eder found that all dyes which act as good sensitisers are substantive colours, and have the power of staining the granules of silver bromide. They also show a strong and well-defined absorption band in the solid condition (*i.e.*, in a dry gelatin film). When the dye is once associated with the silver bromide it cannot be entirely removed even by prolonged washing, just as the gelatin in the gelatino-bromide cannot be completely washed out. At the same time many dyes which fulfil these conditions exert very little sensitising action.

No definite connection has yet been traced between the sensitising action of the dyes and their general physical and chemical properties.[‡] Eosin is strongly fluorescent, erythrosin and rose Bengal are not. Aniline red and many others show anomalous dispersion, but some of the best sensitisers do not. Compounds of similar constitution as a rule behave similary, but to this there are many exceptions. Fluorescein and benzyl-fluorescein both sensitise for green, and the haloid derivatives of fluorescein sensitise for greenish-yellow or yellow, but the nitro-derivatives exert very little sensitising action. Phenol phthalein, orcein phthalein and their derivatives have very little sensitising effect. Benzaldehyde green and its sulphonic acid are both sensitisers, whilst rosaniline is a sensitiser, but its sulphonic acid is not. Further, isomerides such as orange R and acid orange, do not behave in a similar manner.

In order to determine the relation between the action of the dyes alone upon light, and their action as sensitisers, it is essential to examine the absorption spectra of the dyes in the solid condition, and associated with gelatin, since the absorption spectrum of one and the same substance varies greatly according to the conditions under which it is examined, and the substances with which it is associated.[§] The proper method of examination for this purpose is to dissolve the dye in a solution of gelatin, spread the liquid on a glass plate, and examine the film after drying.

When the absorption spectra thus observed are compared with the sensitising action of the particular dyes, it is found that in every case the absorption band and the band of sensitising effect correspond but do not coincide; the point of maximum sensitising effect is nearer to the red end of the spectrum than the point of maximum absorption. This is due to the association of the dye with the dense particles of silver bromide, the band being displaced towards the less refrangible end in accordance with Kundt's law.[‖] According to Eder's measurements the displacement of the band is equivalent to about 300 tenth-metres. When, however, the absorption spectrum of the dyed gelatino-bromide itself is examined, it is found that the absorption band and the sensitising effect are absolutely coincident, a result which affords further confimation of the fact first proved by Draper,[¶] and firmly established by the researches of Vogel[**] and others, that in order that light rays may produce any effect on a substance they must be absorbed by that substance.

How does the energy of the rays thus absorbed bring about the decomposition of the silver salt? Abney found that when cyanin alone is exposed to light it is decomposed, and the products of decomposition have the property of reducing silver bromide if the two are treated with a developer. It would seem, therefore, that the reduction of the silver bromide is a secondary phenomenon, conditioned by the preliminary decomposition of the dye. Vogel and Eder consider that this is only a special case, and that the explanation will not hold good generally, since many sensitisers are comparatively stable, and cannot undergo appreciable decomposition in the short time during which the plates are exposed to light. Many of the best sensitisers belong, however, to the class of fugitive dyes, and Abney has pointed out that in a dyed gelatino-bromide plate the dye is mixed with a large quantity of silver bromide, so that a very small quantity of dye is distributed over a very large surface, and the decomposition of only a very minute quantity would furnish sufficient nucleus for the commencement of development.

It has already been stated that the dye cannot be removed from the silver bromide by washing, and Eder considers that the dye unites with the silver bromide to form a molecular compound of the nature of a lake. The action of light on the dye and the silver bromide is simultaneous; the compound of the bromide and the dye absorbs the light rays, and the energy which existed as wave-motion is communicated to the molecules of the compound. The molecules are thereby thrown into such energetic vibration that their equilibrium is disturbed, and the silver bromide is either decomposed into bromine and silver sub-bromide, or is brought into that state of unstable equilibrium in which it is readily acted upon by a reducing agent such as constitutes an ordinary

developer. When the light rays are absorbed by the dye alone the waves for the most part undergo *photo-thermal extinction*, and their energy is transformed into heat, a small proportion undergoing *photo-chemical extinction*, and being used up in producing chemical decomposition, since the majority of dyes are slightly altered by light. When, however, the rays are absorbed by the dyed silver bromide the greater part of the waves undergoes photo-chemical extinction, and their energy is used up in decomposing the silver bromide, whilst only a small proportion undergoes photo thermal extinction.

It is very difficult to understand why some dyes should exert such a great sensitising action, whilst others which are apparently very similar in constitution and properties have little or no effect. At present no explanation of the phenomenon can be given. I would point out, however, that the best sensitisers, erythrosin, rose Bengal, and cyanin, etc., have a very complex molecular constitution, a very high molecular weight, and contain a number of atoms of iodine or bromine, and it is very probable that the complex structure of the molecules, and their great weight, may confer upon them the power of entangling and arresting the ether waves to a greater extent than lighter and simpler molecules.

Practical Applications.—The results obtained with the spectrum afford valuable information, but they must not be interpreted literally for practical purposes. The colour sensations produced by pigments, etc., are not always identical in origin with the similar colour sensations produced by the spectrum. Sometimes they are very different. It is well known, for instance, that the sensation of white may result from the simultaneous excitation of the sensations of red and greenish blue, purple and green, bright blue and yellow. The sensation of yellow may result from the simultaneous excitation of the sensations red and green, that is to say, may be produced by rays quite different from the yellow rays of the spectrum. Moreover, all coloured objects reflect a certain quantity of unaltered white light, which tends to reduce the contrasts resulting from differences in colour, and thus to produce truer gradations. The effect of this unaltered reflected light is greater the longer the time of exposure. The amount of light reflected without alteration, depends upon the brilliancy of the illumination, and the character of the surface of the object. If the surface is smooth and bright, the proportion of reflected white light will be comparatively large, and *vice versâ.* In ordinary landscapes the proportion of unaltered reflected light is very considerable, and hence the effect of making the plates sensitive to the less refrangible rays is not quite so strongly marked as in other cases.

Since the maximum sensitising action of different dyes is exerted for different rays, it is evident that the dye may be selected according to the colour which it is desired to bring into prominence; eosin for yellowish green, erythrosin for yellow, cyanin for orange. It will be seen that the curve for ammoniacal erythrosin (Fig. 3, No. 6) approximates somewhat closely to the curve of the optical effect of the spectrum (Fig. 1), and it follows that for general work erythrosin and ammonia will give the best results, whilst a little cyanin may be added to increase the sensitiveness to orange, but this is not usually necessary. No yellow pigment has the same relative luminosity as the yellow of the spectrum, and the difference between the relative brightness of blue and yellow pigments is much less than between the relative brightness of the blue and yellow of the spectrum. Moreover, as already explained, the crowding up of the less refrangible rays in the prismatic spectrum, magnifies the apparent effect of those rays. Hence, although a plate may be more sensitive to spectrum yellow than to spectrum blue, it does not follow that it is more sensitive to the light from a yellow pigment than to the light from a blue pigment. The curves show that the sensitiveness to blue and violet is still very great, and it is found that when photographing by daylight a yellow screen must be interposed between the object and the lens, in order to diminish the intensity of the blue and violet rays by absorbing the greater part of them. With gas or lamp light, a yellow screen is not necessary, since such light is comparatively poor in blue and violet rays, and relatively very rich in yellow rays. This applies equally to the light from ordinary incandescent electric lamps, provided that the current is not forced.

The yellow screen may consist of a piece of yellow glass, free from bubbles, etc., or of ordinary glass coated with collodion or gelatin stained with some yellow dye, such as *aurantia*. In any case the faces of the glass plate should be as perfectly parallel as possible, and the glass may be cut in the form of a circle, which fits inside the hood of the lens, and thus does not interfere with the use of the ordinary lens cap or shutter. A better method is to gum a film of dyed collodion or gelatin to the diaphragms of the lens. It is obvious that the deeper the tint of the yellow screen the greater will be the proportion of blue and violet rays absorbed, and consequently the greater the relative prominence of the yellow and orange, and *vice versa*. The proper selection of the yellow screen enables the photographer to control the character of the result to a very great extent. It is important not to cut off too much of the blue, since if this is done blue and violet will be relatively too dark, and the gradations will be incorrect. Vogel has pointed out* that not unfrequently the shadows of a painting owe whatever luminosity they possess to the presence of blue pigments, and hence if a yellow screen is used, and all the blue is cut off, the shadows are not rendered so well as on an ordinary plate. Again (*loc. cit.*), in the evening the shadows of landscapes, especially at the foot of a mountain, are illuminated almost exclusively by blue rays reflected from the sky, and hence when a yellow screen is used so much of the blue is cut off that the shadows appear far too dark. For certain subjects late in the evening, that is, with the yellow light of the setting sun, no yellow screen is required, and indeed is actually injurious. The use of a yellow screen increases the exposure from about 2 to 10 times the ordinary exposure, according to the tint and intensity of the screen

The plates used for photographing various coloured objects were treated with ammoniacal erythrosin. In the cases described Paget Prize Plate XXX. were employed, but equally good results have been obtained with Wratten & Wainwright's London plates of ordinary rapidity. The plates used in series A, B and C were immersed in a dye solution prepared according to Mallman and Scolik's formula,† which

---

† Photographic Journal, 1886.

is as follows:—Soak the plate for 2 minutes in a 1 per cent. solution of ammonia, and then for 100 seconds in—

Aqueous erythrosin (1 : 1000)	25 parts.
Water	175 ,,
Strong ammonia	4 ,,

The plates used in the other series were prepared in in the same way as the plates used in the spectrum experiments.

After exposure, the dyed plates may be developed either with alkaline pyrogallol or with ferrous oxalate, but in either case care must be taken to keep the developer well restrained, since the dyed plates are much more liable to fog than ordinary plates. Since the plates are highly sensitive to yellow and orange, all the operations must be conducted in weak ruby light, and the plate must be protected as far as possible. A candle protected by the ordinary ruby glass, or by Edwards's ruby paper, answers very well. When, however, the plates are sensitive to red, it is best to use candle or lamp light filtered through several thicknesses of brown tissue paper (Seidepapier), since in this way the maximum amount of luminosity combined with the least chemical activity is obtained. At all times the intensity of the light must be kept as low as is compatible with visibility, and the plate must be carefully protected. After development has proceeded for some time the plate is much less sensitive to rays of low refrangibility. When the plate has been fixed and washed the dye can be more or less completely removed from the gelatin by soaking it in alcohol. It does not appreciably affect the printing qualities of the negatives.

In my own experiments the plates were developed with pyrogallol made alkaline with ammonia and restrained with ammonium bromide. The screen used was glass coated with collodion dyed with aurantia. In each series, except B and C, three exposures were made under the same conditions of lighting—namely, (1) a dyed plate, with a yellow screen fitted into the hood of the lens; (2) a dyed plate, without any screen; (3) an undyed plate, without any screen. In each case the exposure was the same, and hence it is evident that the differences in the results are not due to differences in the time of exposure. Undyed plates exposed behind the yellow screen for the same length of time gave no trace whatever of a developable image. Care was taken to give a full exposure even with the dyed plate and the yellow screen; and it follows that the plates exposed without the screen were very much overexposed. It is obvious that every chance was thus given for yellow, orange, etc,, to register themselves on the plate, and development was conducted in such a manner as to obtain the best possible result in each case, all the usual means being adopted to secure a good rendering of yellow and similar colours on the undyed plate.

A. Subject.—A series of seven bands of coloured paper with a matt surface; red, orange, yellow, green, blue, purple and violet.

1. Undyed Plate, no screen.—Violet, purple, and blue were practically identical, and almost equal to white; green darker; yellow darker still; orange darkest of all; red comparatively light, a result due to the fact that the red was not a pure red, but contained a certain proportion of admixed blue pigment.

2. Dyed Plate, no screen.—Violet, purple, blue, green, and yellow practically identical and almost equal to white: orange somewhat lighter than in 1; red somewhat darker than in 1.

3. Dyed Plate, yellow screen.—Yellow the brightest, green and orange darker and about equal; red, blue, purple, and violet comparately dark, the gradations approximating somewhat closely to the gradations of the colours.

B. Subject.—Bright yellow and brown plate with figures; dark blue and white vase, sage green background.

1. Undyed Plate, no screen.—Yellow plate almost black, the most prominent details only being obtained with great difficulty; vase almost white, the distinction between the white figures and the dark-blue ground being almost completely lost; background too light.

2. Dyed Plate, yellow screen.—Plate almost white, with all the details well rendered; ground of the vase dark, and the figures white; background darker than in 1.

C. Subject.—Various species of *Narcissi* in blue and white vases—viz., white narcissi, daffodils and jonquils.

1. Undyed Plate, no screen.—Jonquils very dark; daffodils almost as dark, though with a considerable amount of detail; white narcissi white; blue of the vases almost indistinguishable from the white.

(2) Dyed plate, yellow screen.—Daffodils full of detail and gradation, and almost as bright as the white narcissi; jonquils slightly darker than the narcissi (they are of a deeper yellow), and their orange centres somewhat darker still; blue of the vases very dark.

These results were exhibited when the paper was read; the following experiments have been made since.

D. Subject.—Dark blue and purple pansies with yellow centres, and bright yellow pansies with blue centres.

(1) Undyed plate, no screen.—The relative gradations are completely reversed, the blue being almost white, whilst the yellow is nearly black.

(2) Dyed plate, no screen.—Yellow and blue practically equal in brightness, and indistinguishable, the details and variations in shade being fairly well rendered.

(3) Dyed plate, yellow screen.—Blue dark, yellow almost white, the gradations being fairly correct, and the details and the variations in the shades of colour very well rendered.

E. Subject.—Primroses and violets in dark blue and white vase.

(1) Undyed plate, no screen.—Primroses well rendered in consequence of the long exposure, but the orange centres of the flowers very dark; violets much too light; vase white, and details almost completely lost.

(2) Dyed plate, no screen.—As No. 1, but centres of the primroses much lighter.

(3) Dyed plate, yellow screen.—Various colours in correct gradations, the violets and the dark blue of the vase being dark, the primroses white, but full of detail, with the orange centres somewhat darker.

F. Subject.—Single daffodils (orange) and hyacinths (white with a slight pink tinge); blue vase, not very dark.

(1) Undyed plate, no screen.—Hyacinths white; daffodils black, though full of detail; vase white.

(2) Dyed plate, no screen.—Hyacinths white; daffodils nearly white, and full of gradation and detail; vase still too light.

(3) Dyed plate, yellow screen.—As No. 2, but blue vase much darker; all the colours rendered in a very satisfactory manner.

G. Subject.—Painting: sun setting (white and orange) behind a church (dark olive grey). Sunset reflected in water, shadow parts of which are blue, like the outer parts of the sky.

(1) Undyed plate, no screen.—Orange much too dark; church and shadows of water too light.

(2) Dyed plate, no screen.—Orange of sunset much brighter, but church and the blue sky and water still too light.

(3) Dyed plate, yellow screen.—The sunset and its reflection bright, the orange being somewhat darker than

the white; the church dark; blue of water and sky darker than in 1 and 2; all gradations very good.

These results show that with dyed plates, even without a yellow screen, there is a very great improvement in the rendering of the yellow, orange, and green, but blue and similar colours are much too light. When the intensity of the blue, etc., is diminished by means of a suitable yellow screen, the gradations of the resulting photograph on a plate dyed with ammonical erythrosin are a very close approximation to the correct gradations. The chief defect is the very slight sensitiveness to reds, and this can, to some extent, be removed by adding a certain proportion of cyanin. An undyed plate exposed behind the yellow screen for the same length of time gave no trace of a developable image. The sensitiveness of ordinary plates to yellow, etc., is so small that if the blue and violet rays are cut off, an exposure of several hundred times the usual exposure would be required, and even then the gradations would not be correct, for the sensitiveness to green would be greater than to yellow, and still greater than to orange, whereas the sensitiveness to green and orange should be nearly equal, and the sensitiveness to yellow should be very much greater.

Note.—In landscape work Obernetter obtained very good results with plates dyed with azalin, and since this paper was read the author has been able to photograph landscapes under exactly the same conditions of lighting on both ordinary plates and plates dyed with ammoniacal erythrosin.[*] The difference is much greater than was anticipated, and is especially well marked in the case of yellowish green foliage, or indeed foliage of all kinds, and the distance. The first result is due to the sensitiveness of the plates to yellow and green; the second to the use of a yellow screen which cuts off the blue haze that usually interferes with the rendering of the distance. The "values" of photographic pictures obtained with the dyed plates and a yellow screen are very fairly correct, and are a very great improvement on the values obtained in the ordinary way.

Spectrum Photography.—Considerable use of dyed plates has been made by Dr. Hasselberg, of the Pulkowa Observatory, for photographing the less refrangible region of the spectrum, and he gives the following formulæ.[†]

From C to wave-length 5600.

Cyanin alcoholic solution (1:400)	2	parts.
Ammonia	1	,,
Distilled water........................	100	,,

From wave-length 5600 *to F.*

Chrysaniline solution (1:1000)	3	,,
Eosin solution (1:1000)	5	,,
Ammonia	1	,,
Distilled water	100	,,

The plates are steeped for about a minute in a weak solution of ammonia, and are then immersed in one of the above solutions for two or three minutes. The plates thus prepared are very sensitive, and the negatives obtained are highly satisfactory, the lines being sharp, dense, and well defined.

The effect of the dyes on the general sensitiveness of the plates is a point of considerable importance, but at present there is no very definite evidence. Some experiments by Eder[‡] indicate that the application of dilute aqueous solutions of the dyes to gelatin plates slightly diminishes the general sensitiveness to daylight, but increases the sensitiveness to gaslight to about twice its ordinary value. According to Mallman and Scolik (*loc. cit.*) the sensitiveness of plates treated with ammoniacal erythrosin is much greater than that of the same plates before treatment. The sensitiveness to daylight is about three times as great, and to gaslight about twenty times as great, this result being due partly to the action of the ammonia and partly to the sensitiveness for yellow rays which results from the presence of the dye. The effect of the sensitiveness for yellow is very marked in the case of gaslight, and it is found that with lamp or gaslight equal to 250—300 candles portraits can readily be taken with an exposure of 3—5 seconds; that is, more rapidly than with the wet collodion process in daylight.

Experiments made by the author show that plates dyed with aqueous erythrosin (1 : 10,000) are distinctly more sensitive to both gaslight and daylight than undyed plates, whilst with ammoniacal erythrosin the increase of sensitiveness is much more marked in both cases. Plates prepared as described above require only about one-third of the exposure of the undyed plates if used without any screen. These results are not in accordance with those of Eder, but the experiments just quoted must only be regarded as preliminary.

Reproduction of Pictures.—Ortho-chromatic plates have been and are being very largely used for the reproduction of paintings, and the numerous fine examples of this kind of work which have recently been produced by the Berlin Photographic Company, Braun & Co., Dixon & Co., and others, are evidence of the very great advance that has been made. In fact it is not too much to say that ortho-chromatic plates, together with the various methods of photogravure and collotype are the methods of the future for the accurate reproduction of paintings.

Vogel [§] has devised a process of photo-chromolithography, which is really an indirect process of photography in colour. It is a modified and improved form of the older process of Ducos du Hauron, who photographed the object through various coloured screens, and thus obtained negatives containing only those parts of the object which had certain colours. These fragmentary images were then transferred to stones, which were used as in ordinary chromolithography, each part of the image being printed in a pigment corresponding with the screen which had been used in taking that particular negative. Ducos du Hauron used only three screens and three pigments, and employed eosin only as a sensitiser. Vogel proposes to use at least six pigments, and to sensitise the plates for red with naphthol blue, for orange with cyanin, for yellow with eosin, for green with safranin, for green-blue with fluorescein, whilst for blue and violet the ordinary sensitiveness of the gelatinobromide plate is sufficient. In taking the various negatives the intensity of the blue and violet is diminished by using a yellow screen. It is evident that the greater the number of spectrum regions treated in this way, the nearer will the resulting chromo-lithograph approach the natural colours. The image on each negative is transferred to a separate stone, and the pigment used with each stone must be complementary to that part of the spectrum for which the plate was made sensitive. These complementary colours are, of course, furnished by the sensitising dyes themselves, and therefore each stone is printed with the dye which was used to produce the negative from which the stone was prepared. Most of the sensitising dyes are, however, of a fugitive character, and hence it is desirable to replace them in printing with permanent pigments which are of the same colour spectroscopically—*e.g.*, aniline blue in place of cyanin.

---

[*] The results of these experiments were exhibited at the Royal Society's soirée on 8th June.

[†] Jahrbuch. f. Photographie, 1887, p. 146.

[‡] Monatsch. f. Chem, 7, p. 1—8.

[§] Annalen der Physik, 1885 [N.S.], 27, p. 130.

There are many points which have still to be settled by further researches, but the results obtained by the various investigators who have directed their attention to this question, together with the successes already achieved in the practical application of these processes, are sufficient to show that orthochromatic methods constitute an advance little, if at all, inferior in importance to the introduction of the gelatinobromide process itself. There can be no doubt that these methods will considerably modify the ordinary practice of photographers, and will increase the value of photography, not only as a method of reproduction, but also as a pictorial art.*

My best thanks are due to my friend, Prof. de Burgh Birch, not only for placing his spectrum-photographic apparatus at my disposal, but also for his kind assistance in the somewhat tedious work of making the exposures.

Journal and Patent† Literature.

IV.—COLOURING MATTERS AND DYES.

Formation of Barium Manganate (Manganese Green). Ed. Donath. Dingl. Polyt. J. **263**, 246—248.

THIS green pigment is one of the few harmless ones, and has the advantage of being unaltered by any basic colour ground, such as lime; it should therefore be useful for fresco painting. By igniting one part of pyrolusite containing 91 per cent. MnO_2, with three parts of commercial barium dioxide in a porcelain crucible, a very good product was obtained of a deep emerald colour with a slight bluish tone. At a higher temperature the colour was destroyed, and only a dark olive-green or grey-brown product resulted. Sulphuric acid or hot potash solution at once decomposed the colour obtained in the above way.—T. L. B.

Benzaldehyde Green Industry. Otto Mühlhäuser. Dingl. Polyt. J. **263**, 249—254 and 295—303.

I. *The Manufacture of Acid Green.*—The leuco-base of acid green is formed when 1mol. of benzaldehyde is condensed by anhydrous oxalic acid, with 2mols. of ethylbenzylaniline, $C_6H_5.COH + 2C_6H_5N.C_2H\ .CH_2.C_6H_5 = H_2O + C_6H_5.CH_2.C_2H_5 : N.C_6H_4.C_6H_5 : C : H.C_6H_4.N : C_2H_5.CH_2.C_6H_5$. This base on sulphonation with fuming sulphuric acid, yields a mixture of di- and tri-sulphonic acids of diethyldibenzyltriphenylmethane, which on oxidation with lead dioxide are converted into the corresponding acid greens.

For the daily production of 150kilos. of acid green are needed four cast-iron jacketed enamel pans, the stirring gear to make about 20 revolutions per minute; the covers to be provided with manhole, pressure-gauge, connections for air-pressure and with the blowing-off still; the jackets provided with both steam and cold water; one blowing-off still with steam coil and free steam pipe inside and a large tap at bottom to empty into a copper steam jacket; one cast-iron jacketed pan for the sulphonation; one liming-out cistern of about 3000 litres capacity; two "montejus," capacity 2000 litres each; one eighteen and one twelve-chambered filter-press; one iron cistern with copper steam coil, holding 6000 litres; one oxidising vat with stirring gear and a capacity of 3000 litres; a smaller reservoir with copper steam coil, holding 1800 litres; three copper evaporating pans provided with stirring scrapers; and lastly, one grinding mill.

The charge for each of the four enamel pans is 21kilos. of benzaldehyde and 80kilos. of benzylethylaniline. The stirrers being set in motion, 34kilos. of finely-sieved anhydrous oxalic acid are slowly added; this takes about one hour. The lid is then closed and the water in the jacket warmed during the first day to 60°, during the next two days to 80° and on the fourth day to the boil. The contents are then neutralised with about 100kilos. of caustic soda solution of 36° B. and, whilst still at 80° or thereabouts, blown over into the blowing-off still. By means of the steam coil the mass is raised to the boil and the excess of benzaldehyde blown off with free steam. The contents are then emptied into the copper jacket and cooled. The lye is removed from the solidified leuco-base and the base washed with water, the oxalic acid being recovered from the washings and lye. By fusing the base in the copper jacket and stirring all day, all the moisture is removed, and when cold the solid leuco-compound is chipped out and finely powdered. The yield averages 93kilos. The sulphonation is carried out in an apparatus similar to the melt pans, into which 200kilos. of 20 per cent. fuming sulphuric acid are placed and 50kilos. of the powdered base stirred in, care being taken to keep the temperature below 45°. When entirely dissolved, the mixture is heated to from 80 to 85°, avoiding a higher or lower temperature. When the product is quite soluble in ammonia the mass is allowed to cool down, and next day it is blown over into the liming-out vat into 1000 litres of water, where the acid is neutralised with about 150kilos. of quicklime, boiled up with free steam and then cooled to about 60—65° by the addition of cold water. The batch is introduced into the montejus and forced by air pressure into the filter-press, the cakes from the latter after boiling up with some 1000 litres water are again filtered and the united filtrates evaporated in the iron cistern down to 1200 litres. This solution is run through an open filter into the oxidation vat and cooled to below 20°. Whilst rapidly stirring, 10kilos. of 66° B. sulphuric acid are added and then as quickly as possible 56kilos. of lead dioxide paste ladled in. After ten minutes' stirring, about 25kilos. of sodium carbonate are thrown in, the temperature raised to 70°, and the solution passed, by air pressure, through the twelve-chambered filter-press which is provided with double filter-cloths. The filtrates are evaporated down to about 600 litres and then to dryness in the copper pans with the stirring scrapers, the drying being finished in the drying-room on zinc trays. The dried green is ground in the mill, forming a dark green powder, the average yield being 85·5kilos.

The above 56kilos. of lead dioxide are obtained by dissolving 22kilos. litharge in 40kilos. of 40 per cent. acetic acid and 100 litres of water, and oxidising with 27kilos. of bleaching powder made into a cream with 54 litres of water, which cream is added until a drop of the lead solution on filter paper no longer becomes yellow at the edge when brought in contact with a drop of the filtered bleach solution. The product is filtered off, well washed and made up with water to 56kilos.

II. *Manufacture of Malachite Green.*—The necessary apparatus for a daily production of 70kilos. green crystals are as follows:—Set of apparatus for production of the leuco-base, consisting of three cast-iron jacketed pans, blowing-off still and copper-drying jacket, as described for acid green. A system of vats for oxidation and precipitation of the colour, being a raised vat for solution of the leuco-base, three vats provided with stirring gear for the oxidation, a set of filters to filter into the three corresponding precipitating vats, and a further set of box filters to collect the colour when thrown down. The apparatus for purification consists of a horizontal boiler to hold 3500 litres provided with stirring gear, a tall dome with manhole, and a second manhole close to the bottom. The boiler is connected with the steam and water supply and also with a pressure filter. This is formed of an iron box divided by a diaphragm of strong

---

* For a full treatment of the subject from a photographic point of view, with the various formulæ, etc., which have been recommended, the author would refer to his articles on "Orthochromatic Photography," in the Photographic News, 1887, pp. 65, 115, 116, 193, 211, *et seq.*

† Any of these specifications may be obtained by post, by remitting the cost price, *plus* postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.........	½d.
Above 8d., and not exceeding 1s. 6d...	1d.
" 1s. 6d., " " 2s. 4d...	1½d.
" 2s. 4d., " " 3s. 4d...	2d.

calico, through the lower half of which the liquor is forced and after passing through the calico run into three precipitating vats, each of which has a box filter for the colour underneath it. For the crystallisation, a vat of 2000 litres capacity is requred for the solution and six other vats of the same size provided with floating covers for the actual crystallisation.

Each charge consists of 100kilos. dimethylaniline and 40kilos. benzaldehyde, to which are slowly (in two hours) added 40kilos. dry powdered zinc chloride. The temperature is maintained the first day at 60°, the second at 80 and the third day raised to 100°. The melt is blown into the still, freed from excess of dimethylaniline with free steam and the base separated from the zinc solution, washed and dried in the manner described for the acid green. The fluid base is poured into zinc trays, each holding 33kilos. net. Average yield of base = 123kilos. The base on one such tray is removed from it by steaming in a vat to hold 400 litres, and then dissolved in about 200 litres of boiling water and 25kilos. of 21 B. hydrochloric acid. The clear solution is next run into one of the oxidation vats containing 1000 litres of water soured with 31kilos. of 40 per cent. acetic acid and there oxidised with 56kilos. of the above described lead dioxide paste. After the reaction is complete (in 5—10 minutes) the lead is thrown down by the addition of 24kilos. of sodium sulphate dissolved in 100 litres of water and the liquor allowed to settle during twelve hours, when it can be easily filtered through felt into the precipitating vat; there the colour is to be precipitated by the addition of 20kilos. of zinc chloride and about 180kilos. of common salt. The colour is collected in filter-boxes and the mother-liquor run to waste. This product from three vats is stirred up in the horizontal boiler with 2400 litres of hot water and boiled for about ten minutes, then some 500 litres of cold water are added, which causes the tar to settle out quickly, and after standing about ten minutes the solution is pressed through a filter into a large vat, where when cooled to 40° C. 100kilos. of ammonia are stirred in to precipitate the base. The filtrates from this precipitate are worked up for the ammonia, while the base is whizzed in a hydro-extractor, the yield of moist base being 85·5kilos. For the crystallisation, 120kilos. of oxalic acid are dissolved in 1200 litres water, raised to the boil and 100kilos. of the above base stirred in. This solution is diluted to 1800 litres and filtered into a slightly conical vat of 2000 litres capacity and when cooled to about 80°, 30kilos. of 20 per cent. ammonia is stirred in as a fine stream. This solution is almost entirely covered by a disc of boards and left to crystallise until the temperature of the vat has fallen to not lower than 18° C. The mother-liquor is filtered from the crystals, which are whizzed in wool bags and finally dried on frames covered with canvas at about 50—60° C. The yield of crystals is about 70kilos. The residual green is obtained as a tarry mass by basifying the filtrate from the crystals at 80° C. with caustic soda, and is worked up for green powder or mixed with violet, etc. The mother-liquors are worked up for the recovery of the oxalic acid. The lead residues from ten batches are boiled up with 2000 litres water, the sulphate of lead allowed to settle and from the clear liquor the green can be recovered as zinc double salt by adding salt and zinc chloride. After a second boil the lead sulphate is dried, ground and used as pigment. By boiling up 200kilos. at a time of the zinc double salt residues with 2000 litres of water and 20kilos. of hydrochloric acid, filtering and precipitating with caustic soda, a further quantity of green is obtained, which is used for making into "green solution," consisting of 50kilos. of green base, 40kilos. of hydrochloric acid and about 200 litres of water.

III. *Manufacture of Brilliant Green*—This is in almost all stages carried out exactly as described above under the head of malachite green, the proportions being: 60kilos. of diethylaniline, 22kilos. of benzaldehyde and 32kilos. of dry oxalic acid; the yield of leuco-base is about 77kilos. The crystallisation however is different, as the sulphate of this green is more insoluble in hot than in cold water. 280 litres of water are placed into an enamelled iron pan holding 600 litres, 120kilos. of sulphuric acid are added and 100kilos. of the base stirred into the warm mixture. When all is dissolved the pan is cooled to about 20°, 130kilos. of 16 per cent. ammonia carefully stirred in and the temperature raised to 55—60° until a slight precipitate is formed. The solution is then filtered into a similar enamelled pan and the temperature quickly raised to 85—90°, when the colour is thrown down in the form of brilliant metallic crystals. These are then filtered off, whizzed and dried, the yield from 114kilos. of green base being 94kilos. brilliant green.

—T. L. B.

The Manufacture of Methylviolet. Otto Mühlhäuser.
Dingl. Polyt. J. **264**, 37—45.

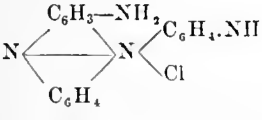
For the daily production of 85kilos. the following apparatus are necessary:—Five cast-iron cylinders, provided with strong stirrers and surrounded half their height by external jackets for steam or cold water. They rest horizontally on bearings and can be inverted for emptying; two large round iron boilers, 2metres broad and 2 metres deep, provided with stirring gear; two large manholes, one at the top and one at the bottom; two taps, one of which is fixed in the lower manhole; three box filters to hold 800 litres; a sulphuretted hydrogen apparatus; two large boiling vats, with stirring gear and a capacity of 3000 litres; six iron pans, with trough-shaped bottom and countersunk rivets, the capacity of each being about 5000 litres; a copper drying pan 120cm. wide and 40cm. deep; a grinding mill and a drying-room.

1st Day.—The Oxidation.—In each of the five iron cylinders 175kilos. of dry and well-ground common salt are placed, the stirrers set in motion and the water in the jackets raised to the boil. To the salt in each vessel 10kilos. of very finely ground sulphate of copper are added and well mixed; then 8kilos. of phenol and 2kilos. of water are poured in and, after about ten minutes mixing, 20kilos. of methylaniline are added. The contents of the drums are now heated up to 55°, the manhole closed and the oxidation allowed to go on for about 2½ hours, the stirrers being kept in motion all the time and the temperature at about 55—60°. The cover is next raised from the manhole and the heating and stirring continued for 5½ hours longer. The at first sticky mass will now have become bronzed and tough and will no longer adhere to the fingers, a sign that the reaction is complete. After a slight cooling the cylinders are inverted and the mass allowed to fall out into a truck, which is then emptied on to a stone floor, where the plastic mass is pressed out into a cake some 3 or 4 inches thick and left all night to cool. *2nd Day.*—This cake is broken up by blows of a wooden mallet into pieces about the size of a man's hand; at the same time 40kilos. of quicklime are slaked with 200 litres of water and the cream strained through a sieve. *3rd Day.*—In one of the large iron boilers 3000 litres of water are placed and the milk of lime added. This mixture is kept stirring by strong iron agitators, the crushed violet cake gradually added, until all the salt and phenol have become dissolved and the violet, hydrated oxide of copper and gypsum are precipitated. The whole is then left at rest over night. *4th Day.*—The clear supernatant liquor is drawn off through a tap near the bottom of the boiler and the precipitate finally washed out on to a woollen filter. This, when well drained, is stirred up with 3000 litres of water, allowed to settle, etc., when, after a repetition of this washing, the precipitate is left over night to drain on the woollen filter. *5th Day.*—The black precipitate is placed in a similar iron boiler, agitated with 3000 litres of water and saturated with hydrogen sulphide, obtained from "soda waste" and hydrochloric acid, and well washed. All the copper is thereby converted into CuS and the separation of the violet from it by means of HCl rendered possible. The bronze precipitate is allowed to settle, brought on to a woollen filter and allowed to drain over night. *6th Day.*—One of the large wooden vats is filled up with 1500 litres of water and the above precipitate stirred in, together with 40kilos. of hydrochloric acid of 21° B. The whole is then boiled up for ten minutes, allowed to settle and the violet solution siphoned off through a wool filter into one of the iron pans. A second boil is made with 800 litres of water and 10kilos. of HCl, the third and fourth boil (if necessary) with only 500 litres of water and 5kilos. of HCl. The residue is thrown away; the violet solution is thrown down by the addition of a filtered salt solution; and the colour forms a tarry green mass at the bottom of the pan. *7th Day.*—The salt mother-liquor is drawn off from the precipitated colour, which is then boiled up in the purification vat with 2000 litres of water and the solution filtered. A second and third extraction is made, the violet precipitated with salt solution and separated (*8th Day*) from the mother-liquor. The violet is then stirred well whilst being heated in the copper steam jacket for about six hours, when it is sufficiently dry to be poured upon zinc trays and allowed to cool. The steam pressure on the jacket must not exceed 20lbs. on the square inch, in order to avoid too high a temperature. *9th to 11th Day.*—The trays are freed from the cooled violet, which is then ground up in a mill and the powder spread on about 40 trays—that is, over a surface of some 15 square metres. This is then dried at about 60° for two days in the drying-room. *12th Day.*—The violet is allowed to cool and then again ground and made up into the various brands by the addition of the required amounts of benzylviolet. The yield of ground violet averages 86kilos. and it consists of a mixture of tetra- and pentamethylpararosaniline.

The raw materials used must fulfil the following requirements:—The methylaniline is dimethylaniline, containing monomethylaniline, as obtained by acting upon aniline with hydrochloric acid and wood spirit, without any fractional distillation. The common salt must be well dried and ground; the crystals of sulphate of copper must be well ground. The phenol need not be pure, a carbolic acid with 10 per cent. distilling below 180° and 97 per cent. below 200° being sufficiently good.
—T. L. B.

The Constitution of Safranines. A. Bernthsen. Ber. **20**, 179—180.

In a previous paper (compare this Journal, 1887, 212) the author endeavoured to show that the safranines are derived from the hypothetical body *phenyl-hydrophenazine* $C_6H_4 : (NH)(NC_6H_5) : C_6H_4$. This view had received much support from the light thrown later on the constitution of toluylene red. He considered that each amido-group of the safranines was combined with each of the benzene nuclei of the phenazine, the correctness of which idea was dependent upon the identity or otherwise of the two dimethylsafranines. Now, according to Nietzki and O. Lehmann (*Ber.* **19**, 3163), these two bodies are not identical; therefore, his theory requires modification and probably in the direction proposed by O. N. Witt and Nietzki (*Ber.* **19**, 3121 and 3163). Therefore, he considers phenosafranine to have the constitution expressed by the unsymmetrical formula:



which only differs in the position of the one amido-group from the one already proposed by him (this Journal, 1887, 213).—T. L. B.

Secondary and Tertiary Quinones. R. Nietzki and F. Kehrmann. Ber. **20**, 322—328.

When a salt of *o*-tolylenediamine is added to a solution of sodium rhodizonate (dihydroxydiquinoyl: this Journal, 1885, 671) in dilute hydrochloric acid, a gelatinous compound  $(OH_2)C_6O_2\left\langle\begin{matrix}N\\N\end{matrix}\right\rangle C_7H_6$ is formed which is soluble in alcohol, acetic acid, and slightly in water. It dissolves in alkaline solutions with a beautiful violet colouration. When made into a paste with water and nitric acid added until reaction commences, it is converted into a substance crystallising in yellow needles, nearly insoluble in cold water, ether, and alcohol; soluble in hot acetic acid. This is a derivative of triquinoyl of the formula  $C_6O_4\begin{matrix}N\\N\end{matrix}\rangle C_7H_6+2H_2O$. This *diquinoyltolazine*, when warmed with an excess of an aqueous solution of a salt of *o*-tolylenediamine, forms *benzotritolazine* $C_6(N_2C_7H_6)_3$, which is very soluble in alcohol and chloroform, and from the latter crystallises in long yellow crystals containing 1mol. of $CHCl_3$, which is only entirely given off at 160°. It is a weak base, soluble in strong acids with yellow colouration and insoluble in water and ether. When warmed with stannous chloride it takes up four atoms of hydrogen but re-oxidises very readily when exposed to the air.

When sodium rhodizonate is condensed with *o*-tolylenediamine in neutral solution (or made acid with a little acetic acid), it combines with three tolylenediamine groups, forming a greenish-grey substance, which oxidises to the above triazine $C_{27}H_{18}N_6$. From these experiments it is shown that triquinoyl contains six quinone oxygen-atoms, but they do not prove that the quinone and hydroxyl-groups in rhodizonic acid are in para position. But, taking this for granted, the fact that adjacent oxygen-atoms react like an orthoquinone group, and are independent of the para-oxygen, gives important support to the ketonic formulæ of quinones.
—T. L. B.

Substitution Products of Azobenzene. J. V. Janovsky and L. Erb. Ber. **20**, 357—362.

Para-bromazobenzene, $C_6H_5.N_2.C_6H_4Br$ [1 : 4], is the chief product of the bromination of azobenzene in acetic acid solution. It crystallises in orange-yellow plates, which melt at 82°. It can be sublimed, and is readily soluble in alcohol, ether, and acetone. On nitration, it gives *p*-nitro-*p*-bromazobenzene, [1:4] $C_6H_4(NO_2).N_2.C_6H_4Br$ [1 : 4]. Fuming sulphuric acid converts it into *p*-bromazobenzene-*p*-sulphonic acid, which is also obtained by bromination of azobenzene-*p*-sulphonic acid. This acid crystallises in flat needles and its sodium salt forms very sparingly-soluble silky needles; on reduction it gives *p*-sulphanilic acid and *p*-bromaniline.

Meta-bromazobenzene, $C_6H_5.N_2.C_6H_4Br$ [1 : 3], forms yellowish-green pearly plates melting at 53—56°, readily soluble in alcohol, ether and acetone, and more sparingly in petroleum ether. Fuming sulphuric acid converts it into *m*-bromazobenzene-*p*-sulphonic acid. It forms crystalline compounds with potassium and sodium salts, which are so insoluble that even 1 per cent. solutions of other potassium and sodium salts are precipitated by the free acid.

Ortho-nitroazobenzene, $C_6H_5.N_2.C_6H_4(NO_2)$ [1 : 2], appears to be the chief product of the nitration of azobenzene in acetic acid solution at 100°. It crystallises in orange-yellow microscopic needles, readily soluble in alcohol, ether, acetone and petroleum ether, and melts at 122—123°. By boiling its alcoholic solution with alkali, an olive-green colouration is produced. By bromination in acetic acid solution, it gives a nitrobromazobenzene, melting at 122—123°. Fuming sulphuric acid converts it into *o*-nitroazobenzene-sulphonic acid, which crystallises in hygroscopic needles and forms very characteristic salts.

Ortho-nitro-azoxybenzene, $C_6H_5.N_2O.C_6H_4(NO_2)$, is formed by the action of fuming nitric acid upon azobenzene in acetic acid when the temperature is kept at about 75°. It crystallises in red plates, which melt at 127°. Both this compound and the *o*-nitro-azobenzene are converted, by reduction with sodium amalgam or by long boiling with alcoholic KOH, into a complicated condensation product (hexazoxy-benzene), $C_{24}H_{18}N_6O$, which is very sparingly soluble in alcohol, ether and acetone, and crystallises from toluene in orange-yellow plates.
—A. G. G

Substitution Products of p-Azotoluene and of Hydrazobenzene. J. V. Janovsky and L. Erb. Ber. **20**, 362—364.

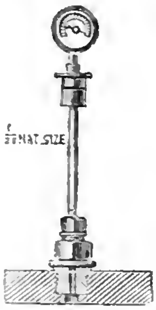
THE bromination of *p* azotoluene in acetic acid solution gives rise to two bromo-azo-toluenes, which melt at 138·5° and 115°. The bromo-azo-toluene, melting at 138·5°, gives on reduction a bromohydrazotoluene, which melts at 119°. By nitration of *p* azotoluene in acetic acid solution two nitro-derivatives are obtained. The one forms orange-yellow monoclinic crystals, which melt at 114°, the other small red tables. If *p*-azotoluene is treated with fuming HNO_3 in the cold, a dinitroazotoluene is formed, which crystallises from acetic acid in light yellow lustrous crystals, melting at 185—187°. By reduction of *p*-bromazobenzene with alcoholic ammonium sulphide, *p*-brom-hydrazobenzene $C_6H_5.N_2H_2.C_6H_4Br$ [1 : 4] is obtained, which crystallises in pearly scales or colourless tables and melts at 115°. By treating the alcoholic solution with H_2SO_4, it is converted into a bromodiamidodiphenyl (monobromobenzidine), crystallising in silvery plates.—A. G. G.

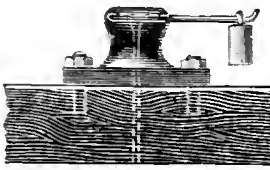
Action of Phenol upon Diazoamidobenzene. K. Heumann and L. Oeconomides. Ber. **20**, 372—373.

IF diazoamidobenzene is gently warmed with phenol (rather more than 1 molecule), *p*-oxy-azobenzene is formed, whilst aniline is liberated. The reaction is a general one; other phenols and other diazo-amides react in a similar manner.—A. G. G.

Manufacture of Dimethylaniline. P. Schoop. Chem. Zeit. **1887**, 253—254.

DIMETHYLANILINE is now no longer prepared by means of methyl chloride, but always, according to Bardy's method, from aniline, methyl alcohol and HCl or H_2SO_4. It is essential for this purpose that the materials should be as pure as possible. The aniline must be free from its homologues, which would give rise to dimethylated bases unsuitable to the preparation of malachite green. The methyl alcohol must be free from ethyl alcohol and acetone. The presence of the latter gives rise amongst other products to a base, $CH_2(C_6H_4.N[CH_3]_2)_2$, and the dimethylaniline thus contaminated is unsuitable for the preparation of either methyl violet or malachite green. The operation is performed in a thick-walled cast-iron autoclave, set in an oil-bath (see figures). A lining to the autoclave is not required when dry aniline salt is employed. The vessel is charged with 75kilos. of aniline, 75kilos. of wood-spirit and 25kilos. of aniline hydrochloride. Although the reaction does not require so high a temperature when more aniline hydrochloride is employed, yet the product is not so pure, since there is a greater tendency to form toluidine. The temperature of the oil-bath is regulated according to the pressure shown by the gauge, and varies between 270—230° C., being highest at the commencement. The maximum pressure is about 27 atmospheres. The operation, which requires about 15 hours, is completed when the pressure begins to decrease without the temperature having been lowered; the fire is then withdrawn. On the following morning, the remaining pressure is let off through the safety valve, the pressure-gauge unscrewed, a pump inserted and the contents pumped out into a separating funnel. The oil (A) is separated from the aqueous portion and the latter treated with NaOH; this gives a second quantity of oil (B). The alkaline liquors, on distillation, furnish a third portion (C). These portions are separately refined and form three qualities of dimethylaniline, of which A is the best and C the worst. The above proportions give on an average 90kilos. A, 19kilos. B, and 11¼kilos. C; thus 120¼kilos. in all from 93kilos. of aniline. For ascertaining the quality of the product, the following tests are employed:—

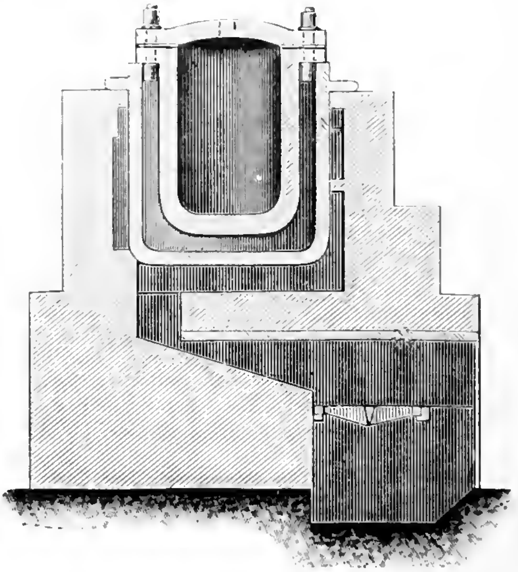




$\frac{1}{5}$ NAT. SIZE.

1. A few drops of the oil are mixed in a watch-glass with a few drops of ether and one drop of concentrated H_2SO_4; if aniline is present aniline sulphate will separate as a white precipitate.

2. The boiling-point gives an indication of the proportion of homologues present; the range should be as small as possible.



$\frac{1}{10}$ NAT. SIZE

3. 5cc. of the dry oil, and 5cc. of acetic anhydride, both at the same temperature, are mixed together with a thermometer; a rise of temperature indicates the presence of monomethylaniline.

4. For the quantitative determination of mono-methylaniline, 100grms. of the oil are treated with sufficient acetic anhydride (usually 5grms.) and the mixture fractionated; after distilling off the dimethylaniline and excess of acetic anhydride, the acetyl-mono-methylaniline remains.

The presence of mono-methylaniline is more objectionable in the preparation of green than of violet. Its quantity seldom exceeds 2% and the best qualities in the market are nearly or quite free from it. When present it can be removed by shaking the oil with a small quantity of dilute sulphuric acid or by boiling with acetic acid for two hours.—A. G. G.

A Process for Producing a new Sulpho-Acid and obtaining Azo-Dyes therefrom. J. Y. Johnson, London. From the "Farbenfabriken vormals Bayer and Co.," Elberfeld, Germany. Eng. Pat. 5846, April 29, 1886. 6d.

THE new acid is described as β-naphthylamine-δ-monosulphonic acid, and it is prepared by the action of an excess of sulphuric acid upon β-naphthylamine at 100—200° C. The acid does not dissolve readily in cold water but is freely soluble in hot water, crystallising out in needles on cooling. The colour obtained by the action of diazotised toluidine upon this acid is bluer in shade than that produced by the same tetrazo-salt with the β-monosulphonic acid. In order to prepare the δ-acid 50 parts of β-naphthylamine sulphate are mixed with 300 parts of sulphuric acid (66° B.) and maintained at 160—170° C. till a specimen withdrawn

gives a bluish-red product with tetrazoditolylchloride. The melt is poured on to ice and the separated acids collected on a filter. The residue is then boiled with water and filtered, in order to remove the insoluble β-acid which is produced with the δ-acid, the latter remaining in the solution and being purified by conversion into the barium or sodium salt and crystallisation. Instead of β-naphthylamine the α- or γ-monosulphonic acid may be employed, both these acids becoming converted into the δ-monosulphonic acid on heating with sulphuric acid above 100 C. The new acid forms a series of azo-dyes when diazotised and combined with phenols, amines, etc., in the usual way or when diazo- or tetrazo-salts act upon it. The patentees give as examples the preparation of the bluish-red colouring matter produced (1) by the action of the diazo-δ-acid upon α-naphthol-α-monosulphonic acid, and (2) by the action of tetrazoditolyl upon the δ-acid.
—R. M.

A Process for the Production of Pararosaniline and its Homologues, as well as mono-, di-, tri-alkylised phenylised or naphthylised Derivatives thereof. H. Baum, Mannheim, Germany. Eng. Pat. 6000, May 3, 1886. 6d.

As an illustration of this process the inventor gives the following:—A mixture is made of 129 parts aniline hydrochloride, 183 parts of paranitrobenzylaniline and 25 parts solid ferric chloride or the same quantity in concentrated aqueous solution. The mixture is heated to 135—140° C. for six hours and then for a short time to 140° C. The reaction is complete in from 10 to 12 hours and the melt is preferably dissolved in ten times the amount of hot water, mixed with 100 parts of hydrochloric acid and 100 parts common salt added. The solution is filtered when cold in order to remove a slight residual impurity. The homologues of pararosaniline are produced by substituting toluidine, xylidine, etc., for aniline, and naphthyl-rosaniline is obtained by the use of naphthylamine. By substituting secondary monamines such as methylaniline, diphenylamine, naphthylphenylamine, etc., for the aniline, mono-substituted rosanilines are obtained. By using paranitrobenzylmethylaniline and the salts of secondary monamines, di-substituted rosanilines can be prepared.—R. M.

The Preparation from Gallic Acid of a Yellow Colouring Matter suitable for Dyeing and Printing. J. H. Johnson, London. From the "Badische Anilin and Soda Fabrik," Ludwigshafen a/Rhine, Germany. Eng. Pat. 6413, May 12, 1886. 6d.

THE manufacture of this dyestuff, termed "galloflavine," is based upon the fact that whereas a solution of gallic acid containing an excess of alkali rapidly oxidises on exposure to the air with the formation of a brown colour which is of no use in the tinctorial industry, a useful yellow colouring matter is formed if the oxidation takes place in the presence of an amount of alkali insufficient to saturate all three hydroxyl groups of the gallic acid. The alkali used is preferably potash in the proportion of two or three molecules of the alkali to one of the acid. The oxidation is effected at a low temperature in dilute alcoholic solution by means of atmospheric air, and is stopped when the maximum of galloflavine is produced. The potassium salt of the colouring matter is insoluble in alcohol, and separates out as a crystalline deposit as fast as formed. As an example the following proportions are given:—5 parts by weight of gallic acid are dissolved in 80 parts of strong spirit and 100 parts of water, and the solution, after being cooled down to 5—10° C., is mixed with constant agitation with 17 parts of caustic potash lye of 1·26 sp. gr. The solution is then oxidised at 0—5° C. by means of a current of air. In order to ascertain the correct point at which to stop the oxidation, a specimen of the solution is filtered, shaken up with air and examined, to see if it contains a precipitate which is insoluble in dilute hydrochloric acid. If no such precipitate is formed the operation is complete, and the crystalline pulp is collected, pressed, dissolved in water at 50° C., the solution acidulated with hydrochloric acid and boiled till the flocculent precipitate becomes crystalline. The colouring matter, when collected and washed with tepid water, may be dried or sent into the market in the form of a paste. Galloflavine forms lakes with metallic oxides varying in shade from greenish-yellow to orange-yellow, and the colouring matter can accordingly be used in a similar manner to alizarin. The chrome lake is said to be particularly fast on cotton.—R. M.

Improvements in Preparing Printing Colours and Solutions of Colouring Matters suitable for Printing and Fixing Aniline Colours upon Cotton or similar Vegetable Fibre. J. H. Johnson, London. From the "Badische Anilin and Soda Fabrik," Ludwigshafen a/Rhine, Germany. Eng. Pat. 6631, May 17, 1886. 6d.

THE patentees commence this specification by pointing out the disadvantages attending the use of the ordinary solvents such as alcohol, wood spirit, methylated spirit, acetic, oxalic and tartaric acids, these disadvantages being volatility or corrosive action upon the fibre during the processes of printing and steaming. The solvent now claimed is a mixture of the acetins of glycerol prepared by cohobating 1 part of glycerol with 1½—2 parts of glacial acetic acid for 48 hours and then distilling off the excess of acid. The residue consists chiefly of a mixture of mono- and diacetin with a small quantity of triacetin. The mode of application is exemplified by the two following typical cases:—(1) For preparing a printing solution of induline, 10 parts by weight of the finely-ground colour (soluble in alcohol) are digested with 40 parts of the acetins at 80—90° C. for one hour. 12 parts of the foregoing solution are then mixed with 85 parts of starch thickening and 3 parts of tannin. The colour is printed and steamed at a low temperature. (2) 10 parts by weight of induline paste, containing 25 per cent. of dry colour (soluble in alcohol), are mixed with 77 parts of starch thickening and 3 parts of tannin, and then 10 parts of the acetin added. The colour is printed and steamed as before.—R. M.

A Process for the Production of Azo-Colours from the Paradiamines of Stilbene and Fluorene. C. A. Martius, Berlin, Germany. Eng. Pat. 7284, May 31, 1887. 6d.

THESE colouring matters are analogous to and are prepared in the same manner as the azo-colours derived from benzidine and its homologues. It is observed in this case, as in that of benzidine, etc., that the tetrazo-salt combines with the phenol, amine, etc., in two steps, so that mixed azo-compounds may be obtained. Seven examples are given:—(1) Diamidostilbene diazotised and the sodium salt of α-naphtholmonosulphonic acid. Dyes cotton bluish-violet. (2) The same tetrazo-salt and β-naphtholdisulphonate of sodium (R salt). Dyes cotton greenish-blue. (3) The same tetrazo-salt with one molecule of β-naphtholdisulphonate and then with one molecule of α-naphtholmonosulphonate of sodium. The intermediate compound is red; the final product dyes cotton bluish-violet. (4) Same as preceding, the α-naphtholmonosulphonate being replaced by α or β-naphthol, or by β-naphtholmonosulphonate of sodium (Schaeffer's acid). Dyes cotton blue or bluish-violet. (5) The same tetrazo-salt and salicylic acid (two molecules dissolved in soda) gives a yellow colouring matter. (6) Diamidofluorene (diazotised) and α-naphthylaminemonosulphonic acid (sodium salt). Dyes cotton a red shade. (7) Same tetrazo-salt and β-naphtholdisulphonate of sodium R. (Shade of colour not stated). All these colours dye cotton directly from a hot alkaline (soap) bath. Diamidostilbene is prepared by the methods of Strakosch (*Ber.* **16**, 328) and Klinger (*Ber.* **16**, 945). Diamidofluorene is prepared by the method described by Schultz (*Ann.* **203**, 100).—R. M.

VII.—ACIDS, ALKALIS AND SALTS.

Some Uses of Dioxide of Manganese. Ed. Donath, Dingl. Polyt. J. **263**, 248—249.

As is well known, manganese dioxide decomposes potassium iodide solution, liberating iodine; this reaction is not due to any ozonisation of the oxygen of the air, as some suppose, for the author found no trace of ozone in a current of air passed for hours over manganese dioxide. The formation of aldehyde, by passing alcohol vapour through tubes containing manganese dioxide (at 100° C.) is applicable for lecture demonstration; the presence of the aldehyde being shown by the reduction of an ammoniacal silver solution. If the dioxide be heated in the usual copper retort for the preparation of oxygen, and alcohol vapour be passed over it, a distillate is obtained, containing acetic acid, ethyl acetate, etc. Hydrogen sulphide is rapidly decomposed when passed over heated dioxide, all the oxygen of which is eventually replaced by sulphur, flesh-coloured manganese sulphide being formed. The author, therefore, again recommends its use for gas purification, and its addition to peat waste used for deodorising purposes. The dioxide is a powerful oxidiser in alkaline solutions, chromic oxide dissolved in potash being rapidly converted into chromate. The author proposes to recover in this way, instead of in the usual dry way, the waste chromium compounds from various technical processes.

—T. L. B.

Manufacture of Acetic Acid from Wood. W. Rudnew. Dingl. Polyt. J. **264**, 88—92 and 128—132.

The first part of the paper gives an account of a series of experiments made by Jakowlew at the author's instigation, the object being to determine the yield of acetic acid obtainable from different woods when subjected to dry distillation. Although similar experiments were conducted by Senff in 1885, the conditions of the working on a large scale being carefully observed, the results obtained were merely useful as a guide for practical work. Jakowlew has, however, determined the yield of acid from perfectly dry woods distilled at uniform temperatures. The experiments were performed in the following manner:—20 to 47grms. of wood in the form of sawdust was dried at 120° and distilled in a glass retort fitted with condenser, the heating being conducted in a bath of Wood's fusible metal. After reaching 150° in the bath, the temperature was raised 1° per minute to 300°. The distillation was now continued without a thermometer until liquid products ceased to come over. Steam was then passed through the apparatus to expel any acid which might have been retained by the residual charcoal. The distillate was filtered and the acid determined in the filtrate by titration with caustic baryta, phenolphthaleïn being used as indicator. The following numbers were obtained:—

	Acetic Acid. Per cent.	
	I.	II.
Linden	10·24	10·17
Birch	9·52	9·29
Aspen	8·06	8·37
Oak	7·92	8·21
Pine	5·65	6·12
Fir	5·24	5·09
Birch bark	2·20	2·38
Cellulose from birch	6·21	—
Cellulose from pine	5·07	—

The object of determining the yield of acid from the cellulose was to study the influence of the composition of different woods on the yield of acid. The cellulose was prepared by macerating the sawdust with a mixture of nitric and hydrochloric acids, boiling the residue with weak ammonia, washing with water and drying at 120°. The above results agree with the generally accepted fact that trees bearing foliage yield more acid than pines. In other respects, however, the numbers are essentially different from those obtained by other investigators, owing to the variation of the conditions under which these trials were made. The fact that the amount of acetic acid yielded by the cellulose is less than that obtainable from most woods would appear to indicate that by the dry distillation of wood the acetic acid is mostly formed from the *lignin*, so that hard woods should yield the largest proportion of acid. This supposition is not, however, substantiated by the above numbers, the linden tree, which is a very soft wood, yielding the largest percentage of acetic acid.

In the second part of the paper, the preparation of pure calcium acetate and pure acetic acid from wood vinegar is considered. The necessary experiments were made by Wienzkowsky in the author's laboratory and the practical conclusions arrived at furnished the foundation of a new process which is said to have the following advantages over the methods at present in use:—(1) An increase in the yield of acid; (2) the production of *pure* acid; (3) the more rapid treatment of wood vinegar. The process consists in distilling the wood vinegar in copper vessels and conducting the vapours through a cooler until methyl alcohol ceases to come over. The vapours are then passed without previous cooling into milk of lime which is kept at a boiling heat and agitated during the whole operation. After finishing the distillation, the mixture is allowed to settle. The supernatant fluid is then drawn off and evaporated to a crystalline consistency, from which the mother-liquor is separated by hydro-extractors, the residual salt being washed with a solution of pure calcium acetate or a small quantity of water. The salt is then decomposed with dilute sulphuric acid and the liquid, after removing the calcium sulphate, distilled. The acid thus obtained may be concentrated by re-distillation with a corresponding quantity of concentrated sulphuric acid. The residual sulphuric acid is employed for decomposing a further quantity of calcium acetate.—D. B.

Manufacture of Caustic Alkalis. W. L. Wise, London. From C. Löwig, Breslau, Germany. Eng. Pat. 4364, Sept. 14, 1882. 6d. Amended Specification.

If a perfect mixture of sodium carbonate with ferric oxide be exposed to a bright red heat, ferrate of soda is formed, which, if treated with hot water, is rapidly decomposed into sodium hydrate and ferric oxide. On this reaction a process for the manufacture of caustic alkalis is based. For the success of the process it is necessary to have a pure oxide of iron, particularly free from alumina and silica. Roasted iron pyrites may be used with advantage, although a loss of soda is hereby incurred in the first instance. But since the iron oxide is used over and over again, this loss will not recur. The iron oxide must not be in too fine a state but rather as a granulated powder, so as to allow of easy and perfect lixiviation. Owing to this circumstance the mixture to be causticised must contain an excess of iron oxide. In practice it has been found that the best results are obtained by dividing the heating process into two operations—viz., the fritting process, and the finishing process. The object of the first is to obtain a mass fused together by sodium carbonate, and which after cooling may be easily powdered, whereby the perfect mixture of the oxide and the soda is secured. The temperature in the first process must be raised up to cherry heat, and must be maintained for about three-quarters of an hour. In the second or finishing stage, the powdered fritted mass is uniformly filled into a muffle and there heated, without stirring, to the necessary temperature, until a sample drawn proves to be free from carbonic acid, which will require nearly the same time as the fritting process. Instead of a muffle, a reverberatory furnace may be employed, which for this purpose is preferably divided by a low bridge, so that the one part may be used for fritting, whereas the hotter part is used for finishing. When the finished mass is withdrawn, the mixture in the adjacent compartment in its first stage is removed to the finishing compartment, and the first compartment immediately re-charged with a fresh mixture. The finished melt has a dark greenish colour, and is heavy, hard and of sandy granulation. For the purpose of lixiviating, a large iron cylinder is used into which a second cylinder of smaller diameter is inserted, the latter being provided with a funnel-shaped exit pipe. The space between the two cylinders is filled with water which may be heated by steam. The bottom of the inner cylinder is covered with an iron sieve upon which a layer of coarsely-powdered iron oxide is spread, and upon this a second layer of oxide of iron finely powdered to cover the bottom uniformly like a filter-bed. The "ferrid" to be lixiviated is sifted through a coarse sieve, and the inner cylinder filled with it up to three-fourths of its bulk. Cold water is added simultaneously, so as to moisten the mass, which contains, besides some undecomposed sodium carbonate, all the impurities of the original soda ash, such as sodium sulphate, chloride, etc. These impurities are washed out by the cold water, which, however, does not act upon the "ferrid." The water in the outer cylinder is then raised 70 to 80° C., and after half-an-hour's time the "ferrid" is decomposed, and the lixiviation performed with hot water. The concentrated lye when first drawn off is perfectly clear, but on cooling it deposits a few flakes of iron. If it is required to produce solid sodium hydrate, the solution may be immediately evaporated. The iron oxide remaining after the lixiviation has a red colour and contains more or less sodium hydrate, according as the lixiviation has been more or less perfect. It is, of course, used over and over again. If potassium carbonate be treated in a like manner, potassium hydrate is produced.

The amendment consists in the deletion of the words *Caustic Baryta and Caustic Strontia* from the title of the original specification and the variation of the proportions of the iron oxide and sodium carbonate employed.—S. H.

Improvements in the Manufacture of Carbonate of Soda and of Carbonate of Potash, and in the Treatment of Residual Products obtained in such Manufacture. C. F. Claus, London. Eng. Pat. 4922, April 8, 1886. 6d.

ALKALI WASTE is decomposed by carbonic acid and the sulphuretted hydrogen evolved, mixed with a sufficient quantity of air, is passed through masses of heated brickwork, where it is burned to sulphurous acid and steam. This gas, after travelling through a heating apparatus, is then passed into a Hargreaves cylinder filled with sodium chloride, on which it acts in the well-known manner, forming sodium sulphate and hydrochloric acid. The latter is condensed, while the former is converted into sodium carbonate or hydrate by the Leblanc process, thus yielding again alkali waste. The Hargreaves process may be also modified in so far that instead of charging the decomposer with sodium chloride alone, it is filled with a mixture of small coke and sodium chloride. By the action of sulphurous acid the contents of the decomposer are converted into a mixture of coke and sodium sulphate. This mixture is then heated to a temperature at which the sodium sulphate is capable of being reduced to sodium sulphide. When this heat has been reached, water-gas—*i.e.*, a mixture of carbonic oxide and hydrogen, previously heated, is passed through the mass until the sodium sulphate is reduced to sulphide. The latter is then subjected to the combined action of carbonic acid and steam, whereby it is converted into sodium carbonate, whilst sulphuretted hydrogen is liberated. The former is lixiviated and the residual coke mixed again with fresh sodium chloride. The sulphuretted hydrogen is burned to sulphurous acid, which is made to act on further quantities of sodium chloride. When heated water-gas is passed through the mass of heated sodium sulphate and coke, the carbonic oxide in it becomes oxidised to carbonic acid, which latter is used for the decomposition of sodium sulphide.—S. H.

Improvements in Apparatus for Extracting and Subliming Sulphur. J. Y. Johnson, London. From C. Dubois, Marseilles. Eng. Pat. 7129, May 27, 1886. 8d.

THE apparatus relates to the extraction of sulphur from ores, and is also applicable for the sublimation of crude sulphur. It consists of a retort or chamber in which the materials are subjected to the action of superheated steam. The retort is mounted on hollow trunnions, one of which is used for the admission of steam, whilst the other serves for the escape of the sulphurous vapour. The retort has a rotary motion imparted to it by means of a worm and worm wheel, and is enclosed in a chamber of brickwork in which the products of combustion from a furnace are caused to circulate. Steam is supplied to the apparatus by a pipe which, after passing through the heating chamber surrounding the retort, enters the latter through one of the trunnions, and distributes the steam throughout the materials by means of perforated branch pipes with contracted orifices. The other trunnion communicates with a box in which the vapourous products can be examined, and whence they can be directed into different receptacles according to their quality.—S. H.

Improvements in the Manufacture of Carbonic Oxide Gas. A. Fritschi, Paris. Eng. Pat. 7192, May 28, 1886. 8d.

THIS invention relates to the manufacture of pure carbonic oxide, and is based upon the property cuprous chloride possesses, of dissolving at a temperature varying between 0° C. and 50° C. twenty times its own volume of carbonic oxide, and of allowing the gas to be disengaged if a partial vacuum is formed above the solution. The apparatus used consists of one or more gas producers worked at a high pressure for the purpose of producing carbonic oxide with a small quantity of carbonic acid, nitrogen and hydrogen. The gases are cooled in a column, into which cold water is injected. Thence they proceed to a leaden casing, forming a barometric tube and reservoir for the solution of cuprous chloride. This casing is traversed by two series of pipes, perforated with a number of small holes. One set of pipes communicates with the gas conduit leading from the cooling column, whilst the other forms the connection with the force pipe of a pump. The object of this pump is to constantly renew the surface by drawing the liquid deprived of carbonic oxide from the upper part of the barometric tube and forcing it through the other set of pipes. An exhauster continuously aspirates the carbonic oxide from the upper part of the barometric tube, and forces it into a pipe communicating with a gasometer. The operation of the apparatus is as follows:—The exhauster is started until the required vacuum is obtained, the pump is then worked, and the gas from the cooling column admitted to the reservoir holding the cuprous chloride solution. The carbonic oxide is quickly dissolved, and removed by the exhauster as fast as it is absorbed. Once started, the apparatus will continue to work for any length of time, as the cuprous solution is not altered in its chemical composition.—S. H.

New or Improved Means or Apparatus for Evaporating Waste Lyes and Recovering Soda from Black-Liquor. B. Dawson, Malvern Link. Eng. Pat. 7859, June 11, 1886. 8d.

FOR the recovery of soda in waste lyes, such as are obtained in the manufacture of paper, incinerators of various types have been used, with none of which it has been found practicable to effect evaporation by surface heating. In order to attain this end the inventor has devised an apparatus for the use of gaseous fuel, which is introduced with a due proportion of air into the furnace in such a manner that the flame may extend over practically the entire surface to be evaporated.

—S. H.

Improvements in obtaining Chlorine. L. Mond, London. Eng. Pat. 8308, June 23, 1886. 6d.

THE invention has for its object the production of chlorine from gaseous hydrochloric acid. The latter is brought into contact at an elevated temperature with nickel protoxide, when the chlorine combines with the base. By exposing this salt subsequently at a suitable temperature to dried and heated air, the original oxide is re-formed, whilst chlorine is given off. The two operations are carried out in one single apparatus, so that no expense is incurred in moving the solid substances used. Instead of nickel, the oxides and salts of those metals can be used which only form one oxide, such as magnesium, zinc, aluminium, and so forth. The compounds of these metals with silicic, phosphoric and boracic acids may also be employed. In order to increase the active surface for the action of the gaseous hydrochloric acid, pumice stone or any porous material is impregnated with the molten chloride or with a solution of the chloride, and after drying the mass is exposed to a current of heated air. The process is best carried out in retorts or cylinders made of earthenware or cast-iron, which latter is preferably enamelled. The gaseous acid and air before entering the cylinders or retorts, are heated so as to reduce the amount of heat which has to be passed through their walls, and by this means the cylinders can be made of a large diameter. A special feature of the process is the complete conversion of the hydrochloric acid into chlorine. Impure hydrochloric acid, which is unfit to be employed directly in the Deacon process, is quite suitable for this process.—S. H.

Improvements in obtaining Sulphide of Zinc from Solutions. J. H. Dennis, Liverpool; and N. Glendinning, St. Helens. Eng. Pat. 8217, June 22, 1886. 6d.

IT is intended to obtain pure zinc sulphide from the solutions which are produced in the manufacture of copper by the wet process, and other metallurgical operations. If the solution contains any metal which in the presence of free acid is precipitated by sulphuretted hydrogen, the solution is treated with this gas until these metals are precipitated, and the said gas is slightly in excess. The free acid is then nearly neutralised by passing the solution through a filter-bed of limestone. The neutralised solution is diluted with water, so that it contains no more than 10 or 11 ounces of zinc per cubic foot, and afterwards subjected to the action of sulphuretted hydrogen, until all the zinc is precipitated, when it is separated in any convenient manner. Instead of diluting with water, the action of sulphuretted hydrogen may be continued until as much zinc as can be is precipitated; the precipitate is then separated, the filtrate neutralised, and again subjected to the action of the gas, this process being repeated until all the zinc obtainable is precipitated. The zinc sulphide is washed with a little acid until all the foreign salts are removed, when the washing is completed with water.—S. H.

Improvements in Apparatus employed in the Ammonia-Soda Process. O. Imray. From La Société Anonyme pour l'Etude et la Création de Soudières, Paris, France. Eng. Pat. 9366, July 19, 1886. 8d.

THE first operation in the ammonia-soda process is the treatment of ammoniacal brine with carbonic acid. The carbonating apparatus according to this invention is shown in Fig. 1. It consists of an annular cylinder, having within the annulus numerous shelves p serrated at their edges, which project from the sides and nearly meet in the middle, and above each pair is a curved deflector p', supported on cross bars T. The vessel being filled up to A with the solution, carbonic acid, admitted at C, is first distributed by the deflector D, and further sub-divided as it ascends through the liquid by the serrations of the shelves p and plates p'. Portions of the liquid and its precipitate of sodium bicarbonate are from time to time withdrawn at R. For the recovery of the ammonia, two vessels are employed, an upper and a lower one, as shown in Fig. 2. The upper vessel A is divided into compartments by horizontal partitions F, having through them mouthpieces E covered by bells with serrated edges. Each compartment is charged with the liquid to a level determined by overflow pipes t from each compartment to the next below, a deflecting plate causing the liquid that enters to flow quite round before it reaches the overflow. The liquid to be distilled enters at D and proceeds downwards through the successive compartments. The gas and steam pass upwards through the mouthpieces E, and past the serrated edges of the bells by which their streams are sub-divided,

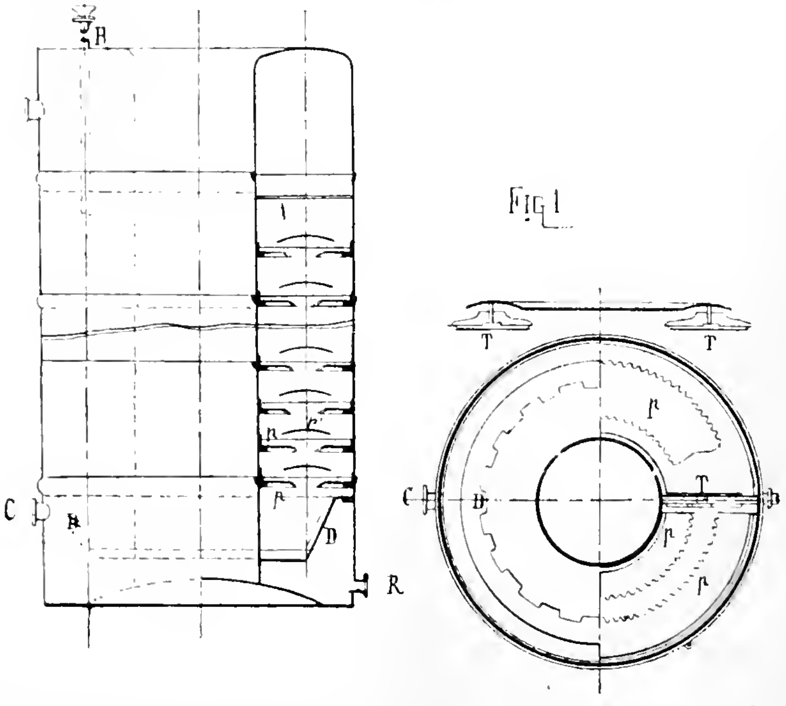


FIG. 1.

causing agitation. The disengaged gases pass away by the pipe H to be condensed. The liquid flows by the pipe N at the bottom of A to the lower vessel B, where the lime treatment is applied. This vessel is also divided into compartments by partitions, each having two mouthpieces with serrated bells K and an overflow pipe T. The latter being alternately at opposite sides, the liquid has in each compartment to pass across from the one bell K to the other. Milk of lime is continuously supplied by the pipe M to meet the liquor from A entering by the pipe N. Thus in the highest compartment the lime acts on the fixed ammonia salts. At the bottom are tubes S heated by steam around them, the steam being thus kept separate from the liquor so as not to dilute it. From time to time a portion of the liquor is run off at U.

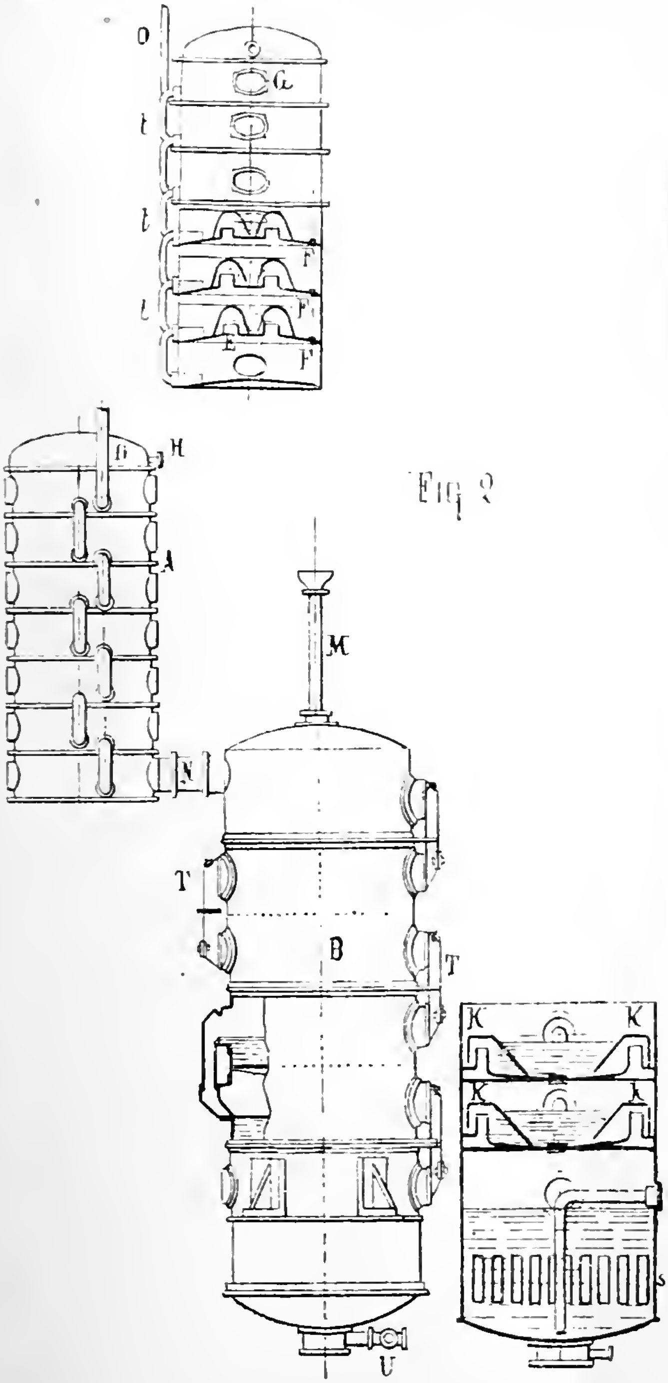

FIG. 2

The calcination of the sodium bicarbonate is effected by the apparatus shown in Fig. 3. C is a rotating cylinder, mounted on rollers G on shafts A, within a furnace chamber heated by a fire on one side. Along the axis of the cylinder extends a shaft B which is driven in a direction opposite to that of the cylinder. One end of the shaft B works on a bearing formed by a pipe T, from which a branch M is directed upwards to serve as an outlet for the gases and vapours liberated during the calcination. To the shaft B are hinged arms carrying two scraper blades L which have indented edges, the projecting teeth of the one blade corresponding in position with the intervals between the teeth of the other blade. P is a manhole for charging and discharging.

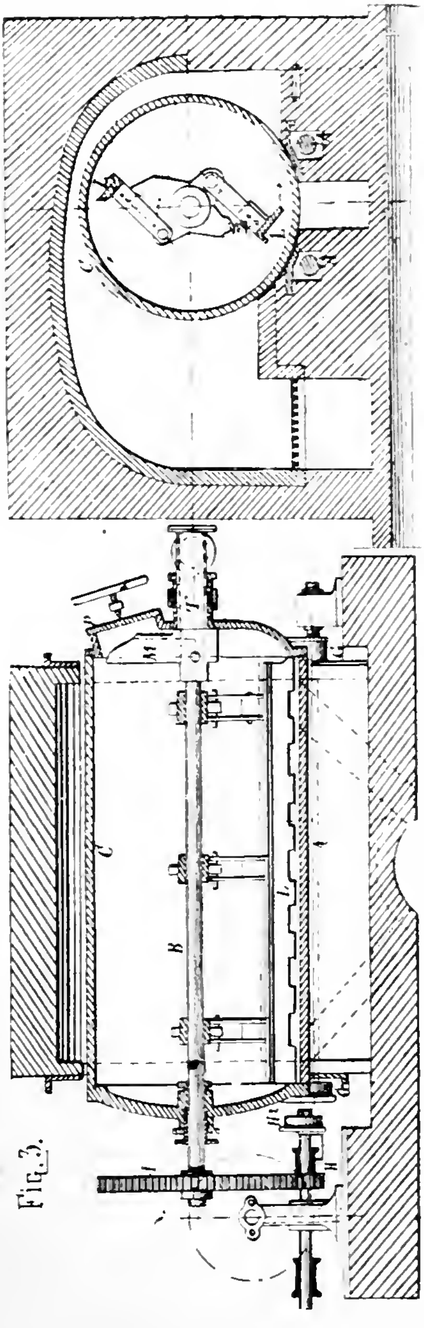

Fig. 3.

Improvements in the Manufacture of Bichromate of Ammonia. J. Park, Glasgow. Eng. Pat. 8602, July 1, 1886. 6d.

Calcium chromate is converted into calcium bichromate by the addition of the requisite quantity of sulphuric acid. Ammonium sulphate either in solid form or in solution is then added, when calcium sulphate is precipitated, from which the solution of ammonium bichromate is separated by filtration. The latter is then boiled down to the point of crystallisation.—S. H.

A Process for Manufacturing the Double Sulphate and Phosphate of Ammonium or Potassium. O. v. Gruber, Viennenburg, Germany. Eng. Pat. 329, Jan. 8, 1887. 4d.

The compound is obtained by heating phosphoric acid, containing from 50 to 54 per cent. phosphoric acid anhydride, to its boiling point (about 150° C.) and adding to it, powdered neutral ammonium or potassium sulphate in molecular proportion. The heating is kept up until the fluid shows an inclination to solidify. It is then poured upon plates, and forms dry cakes, which are readily pulverised.—S. H.

Improvements in Apparatus for Producing Sulphurous Acid in Solution. P. Thomas, Manchester. Eng. Pat. 872, Jan. 20, 1887. 8d.

The apparatus is particularly designed for the manufacture of sulphurous acid in solution, applicable to the same inventor's bleaching process (Eng. Pat. 549, 1882; this Journal, 1882, 406). Sulphurous acid gas from a sulphur burner or a pyrites kiln is passed into a box, which acts as a dust catcher, and has a series of leaden sheets suspended from hooks in an inclined position, so that the gas travelling in a downward direction may leave the solid matter behind. The gas then enters a series of coke scrubbers, in which it meets with a descending current of the sulphurous acid solution, partially exhausted and weakened by use in connection with the bleaching process. Behind the coke scrubbers a steam jet exhauster is arranged, so that the gas in its further progress is forced. At the same time the gas is thoroughly mixed up with the steam, which being immediately condensed by passing through an externally cooled coil pipe, absorbs the greater part of the remaining sulphurous acid. The gas is lastly conducted to a washer, which is continuously replenished with pure water, and extracts the last traces of the sulphurous acid. This washer consists of two boxes bolted together by vertical flanges, one box being destined for the inlet of the gas, the other for the outlet of the liquor on the one hand, and of the pure air on the other hand. The inlet box has a number of perforated tubes fixed to one of its faces. The gas has free access to the inside of these tubes, and on depressing the liquid in the inlet box, is caused to bubble up through the perforations and the liquor in the outlet box.—S. H.

Improvements in Condensing Chambers for Sublimed Sulphur. J. Y. Johnson, London. From C. Dubois, Marseilles, France. Eng. Pat. 4133, March 18, 1887. 4d.

In a previous specification (Eng. Pat. 7129, 1886; see abstract, p. 439), an apparatus was described for the sublimation of sulphur. The sublimed article, however, is obtained in a very moist condition, and requires to be dried before it can be placed in the market. In order to dispense with this necessity, the receiving chamber in which the sulphur is collected is provided with a cloth stretched at a suitable height above the floor. The sulphur is deposited on this cloth, but the water of condensation filters through it, and is drained off along suitable inclines. The whole or part of the sides and roof may be made of cloth, thus providing for the escape of uncondensed steam, which causes back pressure, and is liable to retard the sublimation of the sulphur in the retort.
—S. H.

An Improved Furnace for Recovering in an inodorous manner the Salts contained in the Lyes used in the Manufacture of Wood Fibre. C. F. Dahl, Danzig, Germany. Eng. Pat. 4600, March 28, 1887. 11d.

The alkaline lyes, resulting from the manufacture of wood fibre, contain the incrusting substances of the wood, straw, etc., which are destroyed by a fusion process, in order to recover the alkali. In this fusion process, as well as during the concentration of the liquors, very offensive gases are given off, which cannot be led away through chimneys into the open air on account of their penetrating smell. The object of this invention is to prevent a nuisance being created by these gases, and this end is attained by a particular process of evaporation, and by the complete combustion of the smouldering gases. The recovery of the alkali takes place in three stages. 1. The liquors are evaporated to a strength of 40° B., by surface heating; the vapours given off not being offensive, are led away through the chimney. 2. The concentrated lyes are boiled down to the consistency of mud, in a fire-proof vat, by an open fire. The smouldering gases which are liberated flow into an auxiliary fire arranged beside the vat, and are thus intimately mixed with heated air and completely burnt, whereupon they are led underneath the pans for the concentration of the dilute liquors. 3. The mud is fused in a retort-shaped furnace, where the incrusting matter is converted into gas. This gas, mixed with hot air, enters the main fire of the inspissation vat, where it is burnt, thus aiding the evaporation. The specification contains a large number of drawings of furnaces, in which these principles are applied.—S. H.

VIII.—GLASS POTTERY AND EARTHENWARE.

Notes on the Analysis of Clay. Meineke. Rep. Anal. Chem. **7**, 214—217.

The proportion between silica and alumina in clay is of the greatest importance for ceramic purposes. Nevertheless, the usual process of analysing clay contains two sources of error which are mostly lost sight of. The silica separated in the usual manner, not only always contains alumina, but is also soluble after drying at 110° C. to an appreciable extent. It is true these two errors sometimes equalise each other, but it is shown by a series of analyses that this is often not the case. It may be especially pointed out that in well-burnt samples of clay the silica may contain as much as 2¼ per cent. of alumina.—S. H.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

On the Behaviour of Sand containing Peat and Humus in the Preparation of Mortar. O. Lieven. Dingl. Polyt. J. **263**, 342—343.

The author shows that sand containing peat or humus cannot be used in the preparation of cement, as the cement does not set. Experiments are described in support of this statement.—S. G. R.

XI.—FATS, OILS AND SOAP MANUFACTURE.

Improvements in Treating and Purifying Paraffin Wax, and in Apparatus therefor. R. Tervet and F. Alison, Renfrew. Eng. Pat. 8756, July 5, 1886. 1s. 1d. Complete Specification accepted, May 6, 1887.

The apparatus described here, with the aid of several sheets of drawings, is intended to lessen the manual labour and the cost of the apparatus employed in purifying paraffin wax by the process technically known as "sweating." Blocks of paraffin, moulded in external stationary vessels, are slowly drawn through the sweating stove, while supported on canvas bands; or the vessels themselves, containing blocks of paraffin, are arranged on carriages and run through the stove. In both cases, gutters, pipes, etc., are provided to carry off the liquid drainings.—W. L. C.

Means for Bleaching and Disinfecting Animal, Vegetable, or Mineral Oils and Fatty Matters. A. Brin, London; and L. Q. Brin, Paris, France. Eng. Pat. 10,968, August 27, 1886. 8d.

THE material to be operated upon is subjected to the action of oxygen exactly as described in the following abstract. When bleaching is desired, the oxygen may be electrically converted into ozone, according to Eng. Pat. 11,846 of September 17, 1886. Chlorine gas may be similarly used in the same apparatus.—W. L. C.

Improvements in the Oxidation of Oils for Use in the Manufacture of Paints or Varnishes, or for other Purposes to which Oxidised Oils are applicable. A. Brin, London; and L. Q. Brin, Paris, France. Eng. Pat. 12,652, Oct. 5, 1886. 8d.

GASEOUS OXYGEN is made to pass in a finely-divided stream through the oil to be oxidised, which is placed in a close vessel provided with a steam jacket and a mechanical agitator, a drawing of which vessel is given. —W. L. C.

Improved Apparatus and Means for Extracting, Washing, and Condensing Fat, Grease, Glue, Oil, or other Substances from Bones, etc. W. Büttner, Gummersbach, Germany; and J. G. Haller and J. Magnus, London. Eng. Pat. 2615, Feb. 19, 1887. 8d.

THREE separate modifications of very complete apparatus for extraction by volatile solvents are described and figured in detail, viz:—(1) For use when the solvent is lighter than the extract; (2) when it is heavier; (3) specially for "de-greasing" woollen and other fabrics. In this last, a revolving cage is used to contain the fabrics. Special precautions are taken to ensure the complete recovery of the solvent.—W. L. C.

An Improved Lubricant. A. G. Wass, Bermondsey. Eng. Pat. 3832, March 14, 1887. 4d.

ASPHALTUM is dissolved in shale oil, tar oil or other medium; to the solution may be added glycerin and litharge or ashes of zinc, lead, or tin.—W. L. C.

An Improved Lubricant. A. G. Wass, Bermondsey. Eng. Pat. 3833, March 14, 1887.

RESIN is dissolved in any convenient oil, and litharge or ashes of lead, zinc or tin is incorporated with the solution, and sometimes any suitable animal, vegetable or mineral greases.—W. L. C.

An Improved Arrangement of Apparatus for Expressing Oil from Oil-yielding Vegetable Substances, and Converting the Residue into Oil-cake. H. Lambert and G. Greenwood, Leeds. Eng. Pat. 5277, April 15, 1886. 11d. Complete Specification accepted April 15, 1887.

THIS patent, illustrated by twelve figures on four sheets of drawings, describes a complete and compact arrangement of portable mechanism specially suited for the requirements of landowners, manufacturers and others using or dealing in oil or oil-cake in the colonies and India. It is designed to enable one attendant to crush all the seed of a moderate-sized holding, and to produce at once a marketable commodity. The engine and boiler, the crushing rolls and kettle, the consolidating or moulding press and the force-pumps for the oil-extracting press, are all mounted on one and the same cast-iron bed; the oil-extracting press and the cake-parer each have their own separate cast-iron beds, but all the machinery is worked from the same source of power.—W. L. C.

XII.—PAINTS, VARNISHES AND RESINS.

On the Varieties of Caoutchouc and Estimation of their Value. Franz v. Hohnel. Dingl. Polyt. J. **263**, 236—240.

THE various sorts of rubber, of which there are some hundreds in the market, may be divided into eight classes, according to their mode of preparation. I. In the first method the milk is poured in thin layers in a mould and dried slowly in hot smoke. The best "Para" rubber belongs to this class. For the finest quality the layers, often over 100 in number, should not exceed 0.5mm. in thickness, and they appear white or greyish, being divided by black smoke lines; the presence of air bubbles or thick layers are signs of poor quality. II. The milk is allowed to flow from the plant into little hollows dug in the soil and is allowed to dry there. This is a very rough method and can only be used in dry seasons. The product is very impure and contains much water. III. Some water is added to the fresh milk and the mixture allowed to stand a few days, when the precipitated rubber is kneaded, pressed free from the excess of moisture and dried in the sun or smoked. IV. The milk is caused to coagulate quickly by the addition of alum, brine or an acid, etc., and the coagulum pressed and dried. The rubber obtained by either of these two processes is of poor quality, and contains much water. The drying is often effected at too high a temperature, the product being rendered "tarry." Such sorts are of the least value. These processes are much used in the north of South America, also in parts of India, Central America, West Africa and the Sunda Islands. Sections of fresh samples of these sorts show a dry rind and a large soft opaque spongy kernel of a whitish-violet, yellow-red or flesh colour; they are generally free from bark or wood chips. V. To the milk is added from four to eight times its volume of water, which causes the rubber to rise as a cream to the surface. This cream is repeatedly washed and then dried. The product is good; certain Central American sorts come in this class. VI. The milk is simply allowed to evaporate in shallow vessels. The quality is good. VII. The milk, being very concentrated, is allowed to flow out on the arm of the collector, where it quickly dries and is rolled off in the form of a ring or—VIII. It runs over the bark of the tree or falls on the ground, being afterwards made up into balls or spindles. Rubber thus obtained is usually very dry and hard, but often contains as much as 30 per cent. of wood chips and bark; the colour varies from yellowish-red to brown. To this class belong the "Thimbles," "Rings," "Spindles," "Niggers," "Scraps," etc. Of course the amount of water a sample contains is an important point to be considered in its valuation, as some varieties contain over 50 per cent.—T. L. B.

XIV.—AGRICULTURE, MANURES, Etc.

On the Slow Enrichment of the Ground in Iron by the Employment of Artificial Manures. E. Jensch. Chem. Zeit. **11**, 136—137.

MANY farmers have feared that the use of Thomas phosphates and other fertilisers containing much iron, might in time cause such an accumulation of iron in the soil as to prove injurious to the crops. The author shows that this fear is groundless. If the depth ploughed is taken at 25cm., the volume of earth employed for cultivation will be 2500cm. per hect., equal (sp. gr. = 2—3) to a weight of 5750 tons. If 400kilos. of phosphate is used annually per hect. and its average value of iron is taken at 9 per cent., the weight of iron annually added will be 36kilos. Hence, even if no allowance is made for the removal of iron by crops, 597 years will be required to raise the iron-value of the soil 1 per cent. —A. G. G.

Ammonium Phosphate as a Manure. K. H. Neuffer. Chem. Zeit. **11**, 137.

THE author claims to have been the first to introduce this substance into commerce. It is now manufactured cheaply by three German firms. The commercial product consists chiefly of the mono-ammonium phosphate $(NH_4)H_2PO_4$.—A. G. G.

Injurious Action of Sodium Nitrate. K. H. Neufler. Chem. Zeit. **11**, 399.

BARLEY grown on a soil that has been manured with sodium nitrate is unfit for brewing purposes in consequence of the barley being too rich in proteids (albuminoids).—S. H.

Analysis of Freshly-fallen Leaves. Loges and Emeis. Bied. Centr. **16**, 135.

—J. W. L.

Influence of the Sp. Gr. of the Seed on the Production of Cultivated Plants. E. Wollny. Forsch. auf d. Gebiet d. Agrikultur Physik, **9**, 207—216.

IN investigating this subject the author took into account, not merely the sp. gr. of the seed, but also their absolute weight. He set potatoes of different sp. gr., but of as nearly as possible the same size, in distances of 60cm. from each other, and from the results obtained at the time of ripeness of the crop the author concludes that the difference in sp. gr. of the seeds has no perceptible influence on the quantity and quality of the crop.
—J. W. L.

The Russian Black Earth. E. Brückner. Der Naturforscher **19**, 313—315.

THIS earth, which is found in South and West Russia, contains from 2—19 per cent. of humus substance. It appears to be in two layers of about 0·5 metre each, the upper one of which consists of a homogenous light loam, containing a close network of fine grass roots, while the lower one is completely undermined with mole holes. According to Dokutschajef, this black earth is formed from the remains of charred roots. The author suggests that the accumulation of dust has also taken part in the formation. The subsoil is in general loess, besides slate, limestone, sand, etc. The influence of the climate on the formation of this earth appears to be considerable; great heat and drought hindering the growth of the steppe grasses, followed by cold and lasting snow, which limit the period of vegetation to several months only, must be unfavourable to it.—J. W. L.

Analysis of a Description of Maize from Cameroon. B. Schulze. Der Landwirt. **22**, 543.

This corn is long, of a very light yellow colour, somewhat large and has an average weight of 0·209grm.
—J. W. L.

Methods of Storing Potatoes. G. Neuhaus. Deut. Landwirtsch. Presse, 1886, No. 80.

As it is difficult to control the temperature, moisture, etc., of a large quantity of potatoes when put together in one heap, the author suggests keeping them in pits 1—1½ft. deep and 5—6ft. wide. They should be at first covered with only a few inches of loose earth, with good ventilating shafts, and the temperature regularly noted. If it rises to 10° C., they should be uncovered on the first dry day, taken out, riddled from sand and again replaced. When the temperature of the atmosphere has sunk to 7 or 8° C. on the approach of winter, they should for the first time receive the winter covering.—J. W. L.

On the Examination of Barley. W. Hoffmeister. Landw. Jahrbücher. **15**, 865—871.

THE author having now examined a large quantity of barley as he examined the oats (this Journal, 1887, 45), especially with regard to the proportions of nitrogen and P_2O_5, he arrives at the following with regard to the development of barley on well-manured ground :—

1. The average weight of the seed varies in inverse proportion to the proteïn.
2. The size of the seed varies indirectly with the per cent. of proteïn.
3. Seeds of the same size do not necessarily contain the same per cent. of nitrogen ; this depends rather on the manure.

Proportion of P_2O_5 to Nitrogen.—The figures in the table refer to the dry substance. In comparing the small seeds with the largest ones, the latter are represented by 100 :—

DESCRIPTION OF SEED.	Proportion of smallest to largest.	Ash, per Cent.			P_2O_5, per Cent.			N, per Cent.			P_2O_5 : N.		
		Large.	Medium.	Small.	Large.	Medium.	Small.	Large.	Medium.	Small.	Large.	Medium.	Small.
Chevalier Barley	62·3	2·650	—	2·720	1·192	—	1·200	1·597	—	1·571	1 : 1·124	—	1 : 1·310

According to these results the P_2O_5 is just as high in the least, as in the most nitrogenous.—J. W. L.

XV.—SUGAR, GUMS, STARCHES, Etc.

The Amount of Sugar in Certain Descriptions of Oil Cakes. G. Burkhard. Neue Zeits. für d. Rübenzucker Ind. **17**, 206.

THE author finds that most oil cakes contain but a very small quantity of sugar, but earth-nut cake contains 4 per cent. of cane sugar.—J. W. L.

On the Quantity of Juice in the Sugar Beet. Bied. Centr. **16**, 197.

IN a series of papers on this subject, Petermann, Pellett, Scheibler and Sidersky have given the results of experiments, and have discussed the conclusions which may be drawn therefrom. Petermann's results give 95 as the percentage of juice. On the other hand, the results obtained by Scheibler by extracting with alcohol for the sugar determination, led Petermann to deduct 0·5 per cent. from the per cent. of sugar obtained by multiplying the per cent. found in the juice by 0·95. Sidersky has come to the conclusion that in pressing the juice from the sugar beet for analysis, it becomes more concentrated by diffusion.

Pagnoul deducts not only the 0·5 per cent. as suggested by Petermann, but also 0·17 per cent. as a correction for the volume occupied in the flask by the precipitate formed when clarifying with acetate of lead. He has compared the percentage figures obtained by using these corrections in a large number of analyses with those obtained by the alcohol method, and finds them to agree. The same author believes, however, that the alcohol method is the only reliable one.

—J. W. L.

Detection and Estimation of Melitriose (Raffinose). C. Scheibler. Ber. **19**, 2868—2874.

THE author was the first who detected raffinose in the beetroot molasses (this Journal, 1885, 607).

In 1876 Loiseau detected Raffinose in beetroot molasses and wrote its formula $C_{18}H_{32}O_{16}.5H_2O$ (*Ber.* **9**, 732). In 1883 Böhm detected gossypose in cotton-seed (*J. Prakt. Chem.* **30**, 37), and soon after Ritthausen proved that it was identical with the melitose obtained by Johnson and Berthelot from the Eucalyptus mannia, the formula being $C_{12}H_{22}O_{11}.3H_2O$. (*J. Prakt. Chem.* 29, 351 ; also this Journ. 1886, 386).

In 1885 Tollens showed that Loiseau's raffinose, and Ritthausen's melitose were identical, and the results of his analysis of the sugar itself, and of a sodium salt, agreed with the formula $C_{12}H_{22}O_{11}.3H_2O$ (this Journ. 1885, 607, and 1886, 243).

About the same time the author, in conjunction with Tollens, discovered a method by which this sugar could be obtained from beetroot molasses and other beetroot sugar products, and von Lippmann showed that it existed ready formed in the beet itself (this Journ. 1886, 104). The author's own experiments, especially the estimation of the water of crystallisation, seemed to leave no doubt that the right formula was that assigned to it by Loiseau, $C_{18}H_{32}O_{16}.5H_2O$.

Having regard to his nomenclature for the sugars (this Journ. 1885, 541), the author suggests that the various names under which this sugar has been known, up to the present, should be substituted by that of melitose.

Melitriose thus freed from water melts at 118—119° and is very hygroscopic. On account of its great solubility in water it is found in the beetroot molasses, and also in the sugars recovered from these. It seems to form a compound with cane-sugar, possessing a peculiar crystalline form, and cannot command the highest prices. This is, indeed, but right, for if the sugar be estimated with the polariscope it will rotate the ray to a greater extent than pure cane-sugar, and in the refinery give a larger amount of molasses. Of the various processes used to recover cane-sugar from molasses, the strontium one alone separates it from the melitriose, this sugar forming no insoluble compound with strontium. The other sugars recovered from molasses containing, therefore, melitriose, the want of a simple method for the estimation of the melitriose has been much felt, and for some months experiments to this end have been in process in the author's laboratory. It was found that 100cc. absolute methyl alcohol dissolves 9½grms. melitriose, whereas it only dissolves 0·4grm cane sugar. From three different commercial sugars obtained from molasses the author separated very considerable quantities of melitriose by means of wood spirit, and purification by crystallisation out of ethyl alcohol. But the difference in the solubility of melitriose and the saccharoses in absolute methyl alcohol may enable the amount of the former to be determined quantitatively. The author desires to reserve the subject for further investigation.—J. W. L.

Formose. O. Loew. Ber. **20**, 141—144.

THE author criticises Tollens' statement* that formose $(C_6H_{12}O_6)$, the product of the action of an excess of milk of lime on a 3·5–4 per cent. solution of formaldehyde,† does not belong to the glucoses, because it does not yield levulinic acid on treatment with hydrochloric acid. Formose possesses the sweet taste and reducing properties of the glucoses; it also forms a compound with phenylhydrazine. With yeast, however, it does not ferment, nor is it optically active; but the author does not consider the possession of these properties as essential to its being classed among the glucoses. As is the case with levulose, both dilute nitric acid and bromine cause the chain of carbon atoms to break up. With both these reagents, trihydroxybutyric acid is among the products of the reactions. With hydrochloric acid a large quantity of humus substances result and as a by-product, probably a ketonic acid, which does not yield the characteristic silver salt of levulinic acid.—C. A. K.

The Action of Aromatic Diamines on Carbohydrates. P. Griess and G. Harrow. Ber. **20**, 281—282.

THE authors have found that certain diamidobenzenes and their carboxylic acids combine with carbohydrates. If a conc. aqueous solution of one part by weight of diamidobenzene [1 : 2] be mixed with two parts of grape sugar, a few drops of HCl added, and the mixture kept in a warm place for about eight days, a weak base is formed, which is somewhat soluble in hot water and alcohol, from which it crystallises almost completely on cooling, in beautiful white shining needles. It is readily soluble in dilute HCl, from which it may be again precipitated, unchanged, by addition of ammonia. It has a bitter taste, and reduces Fehling's solution. If instead of the diamidobenzene, the diamidobenzoic acid $[CO_2H : NH_2 : NH_2 = 1 : 2 : 3]$ be used, a compound, having the character of an amido-acid, is formed. It is but slightly soluble in boiling water or alcohol, and crystallises out of the former in white shining leaves, which do not reduce Fehling's solution but behave similarly to the sugars on heating in a test tube. The authors have obtained a similar acid to the last by substituting maltose for grape sugar. (See this Journal, 1885, 331.)—J. W. L.

Preliminary Communication. H. Kiliani. Ber. **20**, 282.

THE action of HI on arabinose carboxylic acid produced a dehydro-acid, and a small quantity of caproic acid (this Journal, 1887, 219). Accordingly, this dehydro acid has the formula $C_6H_{10}O_6$. Since further the analyses of the phenylhydrazine compound of arabinose agreed with the formula $C_{17}H_{20}O_3N_4$, it is very probable that the arabinose molecule contains only five carbon atoms.

—J. W. L.

Paragalactin. E. Schulze and E. Steiger. Ber. **20**, 290—294.

THE authors have recently noticed that lupin seeds contain a substance which is insoluble in water, alcohol and ether, and from which galactose may be obtained in large quantities by boiling with dilute acids. In order to investigate the character of the sugar obtained when this substance is heated with dilute H_2SO_4, they prepared a quantity as follows:—1kilo. of finely-ground lupin seeds were extracted first with ether, then several times with cold, very dilute (about 1 per cent.) KHO and finally with water until free from alkali. This residue, which possesses a gelatinous appearance, was next heated half-an-hour with 10 per cent. H_2SO_4, the solution filtered from the undissolved woody fibre, diluted with an equal volume of water and finally boiled for another two hours in order to complete the reaction. After cooling, the H_2SO_4 was precipitated with $BaCO_3$, and the solution then concentrated to a syrup on the water bath at a low temperature. This syrup was boiled with absolute alcohol, and the extract, after concentration on the water bath, was again boiled with absolute alcohol. The alcohol dissolved only a part of the residue, and after allowing the solution to stand for some time, a sugar crystallised out, which was purified by recrystallisation from dilute alcohol. The residue, insoluble in absolute alcohol, was dissolved in 90 per cent. alcohol, the solution concentrated, the residue taken up with water, and the solution, after decolourisation with animal charcoal and subsequent concentration, crystallised completely on standing. The crystalline mass was purified by recrystallisation from alcohol. Both the crystalline products, although prepared from different parts of the principal residue, proved to be one and the same substance—viz., galactose. The specific rotatory power, the melting points, both of the pure substances, and also those of their phenylhydrazine derivatives, the product of oxidation with HNO_3, which was principally mucic acid, and lastly, an examination of the product of the oxidation with Br., proved their identity. There was no other sugar found with the galactose. The constituent of the lupins producing galactose in the manner just described, the authors have named paragalactin. They calculate that the seeds contain about 20 per cent. of this substance. Paragalactin is insoluble in water, even at the boiling point; it is slightly soluble in tartaric acid, which solution reduces Fehling's solution. It produces no sugar when treated with diastase solution. The gelatinous extract obtained by treating the lupins with very dilute KHO, was heated for two hours on the water bath with 10 per cent. KHO. A yellow coloured solution was formed, from which alcohol produced a gelatinous precipitate, soluble in water and again reprecipitated by alcohol. The precipitate was filtered off, freed from water by means of absolute alcohol, and standing over H_2SO_4. Ignition showed it to contain a considerable quantity of K_2O. By treating it with anhydrous acetic acid, an acetic ether was formed, the analysis of which agreed with the formula $C_6H_7O_3(C_2H_3O)_3$. This ether is insoluble in water, alcohol, ether and in a mixture of alcohol and acetic acid. On heating, it commences to decompose at about 225° without previous fusion; it is, therefore, quite distinct from the acetic ether of β-galactan. Although the authors have not been able to prepare the paragalactin in the pure state, they conclude from the above reactions that it may be represented by the formula $C_6H_{10}O_5$.—J. W. L.

Composition of the Seeds of Panicum Miliaceum. A. Beutell and F. W. Dafert. Chem. Zeit. **11**, 136.

THE long-known varieties of this plant, "klebreis" and "klebhirse," are much used in Japan and China as a gum and as a cheap article of food. The seeds owe their glutinous character to a new form of starch—viz., erythroamylum. The latter is starch in which the granulose is replaced by erythrogranulose (probably identical with erythrodextrin). The authors give the following analysis of a specimen of "klebreis":—

	Decorticated Grain.	Cortex.
Protein	12·99%	11·98%
Fat	4·28	6·85
Dextrin	0·26	0·96
Glucose	5·13	4·68
Starch	76·18	60·31
Fibre	0·15	4·98
Ash	1·01	10·21

—A. G. G.

The Real Nature of Starch Cellulose. Griessmayer. Allgem. Bauer- und Hopfenzeit. **26**, 147.

IN order to prove by macro-chemical means that the skeleton-like substance, obtained from starch by treat-

---

* Ber. 19, 2134. † J. Prakt. Chem. 1886, 321–351.

ment with dilute acid, consists of amylodextrose, Nagelli treated 1000grms. of potato-starch with 6 litres of 12 per cent. HCl for 100 days in the cold. A large quantity of the skeleton-like substance was thus formed. It was washed free from acid, sugar, dextrose etc. In the dry state it weighed 300grms. On boiling with water it almost completely dissolved, the small undissolved residue consisting of impurities, fat etc. On freezing the solution, the amylodextrose crystallised out in spheroid crystals.

J. W. L.

Imitation Gum Arabic. Brit. and Col. Drug. 1887.

THIS is a substance said to be offered in the market in three classes, designated as white, light yellow, and yellow. The first two are, it is stated, in appearance a close imitation of the genuine article, the white being in fragments about the size of those in gum mastic, but as light in colour as good picked gum arabic, angular, with conchoidal faces but without the fissures of gum arabic. The light yellow variety is like the above as to size and general appearance, excepting in colour; the masses in this look like "sorts" gum arabic. The yellow appears in masses somewhat larger, cubical, and in colour resemble translucent pix burgundica. They all are said to behave nearly alike, and the described reactions with water (in which no solution, but only intumescence takes place, becoming clear when boiled), iodine (giving no starch reaction), alcohol (with which the solution remains clear, showing absence of arabin) and lead acetate (by which it is not precipitated), should readily establish their fictitious nature. The substance is said to be carrageein obtained from Irish moss, but this mucilage *is* precipitated by lead acetate solution, so that there must be some error.

XVI.—BREWING, WINES, SPIRITS, Etc.

Composition of By-products from a Porter Brewery. By Sir Charles A. Cameron. Brit. and Col. Drug. 1887, 348.

THE following analyses relate to some of the by-products from the largest brewery in the world, namely, Messrs. Arthur Guinness & Sons, Dublin. They are, no doubt, similar to by-products obtained in other breweries, and which might be converted into artificial manures, or constituents of manures, especially where waste heat for evaporating purposes were required.

Residue from vats to which gelatine had been added: 100 parts contain—

Water	87·800
Dry matter	12·200
	100·000

The dry matter yields—

Ammonia	1·244
Ash	1·150

Including—

Phosphoric anhydride	0·381
(Equal to calcium phosphate 0·838)	
Potash	0·040
Soda	0·050
Chlorine	0·100
Calcium sulphate	0·036

The residue, if nearly dried, would therefore yield about of—

Ammonia	8·000
Calcium phosphate	6·000
Potash	0·600

Residue from vats containing no gelatine; 100 parts contain—

Water	77·500
Dry matter	22·500
	100·000

The dry matter yields—

Ammonia	1·836
Ash	2·055

Including—

Phosphoric anhydride	0·320
(Equal to calcium phosphate 0·700)	
Potash	0·100
Soda	0·110
Calcium sulphate	0·080

This residue nearly dried would contain about 2·8 per cent. of calcium phosphate and 0·4 per cent. of potash, and yield 7 per cent. of ammonia. Compressed yeast, 100 parts, contain—

Water	62·30
Dry matter	37·70
	100·00

The dry matter yields by combustion with soda-lime—

Ammonia	3·204

And leaves on combustion—

Ash	2·800

Including—

Phosphoric anhydride	1·690
(Equal to calcium phosphate 3·380)	
Potash (chiefly in union with phosphoric acid)	0·500
Soda	0·230

If converted into a moderately dry substance the compressed yeast would yield fully—

Ammonia	8·000
And of calcium phosphate	4·000
And potash	1·500

EXHAUSTED HOPS.

100 parts contain—

Water	93·840
*Dry matter	6·160
	100·000

*Yielding—

Ammonia	0·314
Ash	0·308

Including—

Calcium phosphate	0·140
Potash	0·035

The amount of water is very large, and the drying of this waste product would be rather costly. This by-product largely exceeds in quantity all the others above described.

Diastase. O. Loew. Ber. **20.** 58.

THE method of obtaining pure diastase by treating the crude substance with lead acetate, was first proposed by Wurtz and not by the author, as stated by Lintner (this Journal, 1887, 296—297). The method works well, provided due precautions are observed. To show the relation of diastase in its chemical composition to other ferments, Lintner compares it with invertin which Kiliani has proved to contain a considerable amount of hop resin. The author stands by his statement (*Ber.* **15**, 1583), that the pancreatic ferments are albuminous bodies closely related, both as regards composition and properties, to the peptones.—C. A. K.

XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, Etc.

(*A*) CHEMISTRY OF FOODS.

Sp. Gr. of Butter, Artificial Butter and other Fats. Sell. Milchzeit. **15**, 460—461.

THE author gives the following densities, determined by König's method at 100° C.

Pure butter never less than	0·866
Other fats and oleomargarine	0·859
75% butter. 25% artificial butter	0·865
50% butter. 50% ditto	0·863—864

and he suggests that 0·866 should be the limit for the sp. gr. of pure butter.—J. W. L.

On the Formation of the Skin on Heating Milk. P. Sembritzky. Milchzeit. **15,** 462.

THE author removed the skin, which forms on the surface of milk when heated, until it no longer formed, and found it to be about 1 per cent. of the milk. It was, therefore, not merely albumen, of which there is only about 0·4 per cent., but he found it to contain casein. This skin forms at temperatures above 50° and may be removed 50 or more times; when it ceases to form any longer, the milk contains no albumen and but little casein.—J. W. L.

The Action on the Milk of Cows fed on the Residuary Liquors of Sugar Refiners. Kirchner. Centr. Blatt. für d. med. Wissensch. 1885, No. 2.

AFTER closely examining the results of an extensive experiment, the author concludes that, provided the cow does not lose her appetite for ordinary foods, the addition of the maize residuary liquors has a decidedly beneficial effect on the milk, both with regard to quantity and quality; whereas the addition of vinasse has, on account of its purgative properties, a prejudicial effect. The author finds, further, that the very greatest cleanliness should be observed in connection with all the various utensils used in the dairy, when using these foods. These liquors, vinasse, etc., especially in a partially fermented condition, contain not only considerable quantities of yeast but are also a very suitable bed for supporting the development of all the lower germs and bacteria, which exert a very detrimental influence on the health of the cow and on the rate at which the milk becomes sour. These germs, which do not pass through the cow into the milk but become transmitted through carelessness into it, have also a serious influence on the keeping qualities of the butter and cheese.—J. W. L.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

The Perennial Scented Grass Anthroxanthum Odoratum. Nobbe. Der Landwirt, **22,** 523.

THE seeds of this grass are being replaced by the small annual grass, *Anthroxanthum Puelii, lec. and lam.*, which also contains cumarin, the valuable essence of the scented grass. This annual grass, *A. Puelii*, grows as a weed and has latterly spread very rapidly in Hanover. It has a less value than the *A. odoratum*, is an annual plant, forms no turf and produces much less hay. The seed ripens the summer after being sown and produces no more than a quarter to one-third the quantity that the *A. odoratum* does, besides possessing a much weaker odour.—J. W. L.

The Polariscope as a Revealer of Adulterations in Essential Oils. A. M. Todd. Amer. Journ. Pharm. April, 1887.

IN examining some spurious oils of peppermint in behalf of the State, observations were made with a Mitscherlich polariscope upon their polarisation. In authentic samples of several peppermint oils prepared by the author, it was found that, though these different pure samples varied slightly in the angle of polarisation, there were found to be *limits* beyond which pure samples did not go. It was found that if a certain essential oil polarising within a certain limit was mixed with another polarising within entirely different limits, the difference in the polarising angle would enable the amount of adulteration to be readily determined. The angles exhibited by five samples of pure oil of peppermint when polarised were: −55°, −46°, −46°, −52°, −52°, averaging −50·2°. Five samples of natural oil of camphor were also examined, exhibiting an average angle of +65°. Five samples of adulterated peppermint oil averaged −9°, showing a deficit of 40·8°. The variation of the last five samples was at first thought to be due to the dementholisation of the respective oils; but from the fact that oil of camphor (which is dextro-rotatory) is known to be a common adulterant of essential oils, and from his polariscopic observations the author arrived at the conclusion that the impure samples contained an admixture of oil of camphor, the exact proportions in which the polariscope, in skilled hands, was capable of accurately determining. A description of the polariscope recommended by the author for the examination of essential oils may be found in Tucker's work on "Sugar Analysis."

No great progress can be made in this mode of examining essential oils until the indices of refraction of the numerous *pure* oils have been accurately determined; the majority of essential oils in commerce cannot for this purpose be depended upon. The author is now engaged upon special investigations with the oils of fireweed and erigeron.—W. E.

Specific Gravity of some Essential Oils of Commerce as taken from Pure and Normal Samples. From the Report of Messrs. Schimmel & Co., Leipzig.

Name of the Oil.	Temperature of the Oil.			Remarks.
	10° C. (50° F.)	15° C. (59° F.)	20° C. (68° F.)

" Cinnamoni, Ceylon	1·035	1·030	1·027	1·03–1·035

A variation in the above numbers, not exceeding the third decimal figure, would not necessarily imply adulteration, but more considerable discrepancies are not permissible.

Saccharine. Chem. Zeit. **11**, 195.

MAUMENÉ criticises the properties of Fahlberg's saccharine, which he pronounces to be a mixture, since crystals can be obtained from the solution in weak alcohol which contain 13 per cent. of sulphur, whereas the substance remaining in the mother-liquor contains 15 per cent. of sulphur.—S. H.

Hydrastine. M. Freund and W. Will. Ber. **20**, 89—95.

HYDRASTINE is decomposed by dilute nitric acid similarly to narcotine, opianic acid and a base resembling cotarnine being formed (this Journal, 1886, 677). This base, to which the name "hydrastinine" is given, has the formula $C_{11}H_{11}NO_2+H_2O$, whence the formula for hydrastine would be $C_{21}H_{2}\ NO_6$, and not $C_{22}H_{23}NO_6$, as given by Mahla (*Sill. Amer. Journ.* (2), **36**, 57) and Power (*Archiv. d. Pharm.* 1884, 910), unless carbon dioxide is evolved on treating it with dilute nitric acid, which is not the case.

$$\underset{\text{Hydrastine.}}{C_{21}H_{21}NO_6}+O=\underset{\text{Opianic Acid.}}{C_{10}H_{10}O_5}+\underset{\text{Hydrastinine.}}{C_{1}\ H_{11}NO_3}$$

This formula for hydrastine agrees with analyses both of the free base and of its platinum double salt, and has been confirmed by Eykman (this Journal, 1887, 380).

Hydrastinine is a white crystalline body melting at 116—117°, and dissolving in petroleum ether and hot ether. It is precipitated from an acid solution by caustic potash or soda, but not by ammonia or sodium carbonate. Like cotarnine, it contains a molecule of water of crystallisation, which is not present, however, in its salts. Of these the hydrochloride and acid sulphate are readily soluble in water. The former is optically inactive and shows a slight fluorescence in solution, while the crystals of the latter show a green fluorescence. The bichromate and ferricyanide are very characteristic, as well as the gold and platinum double salts. The methiodide is a yellow crystalline body. On reduction with zinc and hydrochloric acid, hydrohydrastinine is formed, $C_{11}H_{13}NO_2$, a base readily soluble in ether, alcohol, etc., and melting at 66°. Its hydrochloride is a crystalline powder, while its hydrobromide forms white needles. When oxidised with dilute nitric acid until caustic potash ceases to produce a precipitate in the solution, hydrastine forms an acid having the formula $C_8H_7NO_4$, isomeric if not identical with apophyllenic acid. Its melting point is 232°, 10° above that of apophyllenic acid.

—C. A. K.

Carveol, Borneol, and Menthol. R. Leuckart. Ber. **20**, 114—116.

CARVOL is reduced to the corresponding alcohol—"carveol"—by means of sodium and alcohol, just as ordinary camphor is converted into borneol.

Carveol boils without decomposition at 218—220° and is characterised by a smell quite distinct from that of carvol. The presence of the hydroxyl-group is shown by the action of acid chlorides and by the formation of acetic and benzoyl ethers, both of which are liquids. Further, when treated with phenylcyanate, phenylcarvylurethane is formed, a crystalline body soluble in hot alcohol and melting at 84°.

$$C_{10}H_{15}.OH+CO.N.C_6H_5=CO{<}\begin{matrix}NH.C_6H_5\\O.C_{10}H_{15}\end{matrix}$$

Borneol and menthol form analogous crystalline compounds, melting at 133° and 111° respectively. The formation of these compounds appears characteristic of the presence of an hydroxyl-group (Leuckart and Bach; *Ber.* **20**, 104) and the author finds that phenylcyanate gives no urethane with either carvol, camphor or monobromocamphor, the sole product of the reaction being diphenylcarbamide, formed from the phenylcyanate by assimilation of a molecule of water and loss of carbon dioxide.—C. A. K.

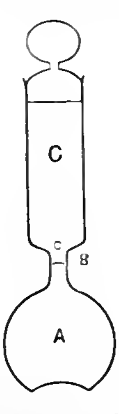
Naringin. W. Will. Ber. **20**, 294—304.

THE author now gives fuller details of the research partially published in *Ber.* **18**, 1311. From 30kilos. of dried *Citrus decumana* blossoms he obtained 600grms. or 2 per cent. of naringin. To this glucoside the formula $C_{21}H_{26}O_{11}$ is assigned. It is a white substance, which dissolves in alcohol and in warm water, crystallising from the latter with 4 molecules of H_2O. The specific rotatory power in H_2O was found to be $[\alpha]_D = 84{\cdot}5°$; in alcohol solution $[\alpha]_D = 87{\cdot}6°$. It decomposes readily when heated with dilute acids. Heated on the water-bath for 6—8 hours with a 2 per cent. solution of H_2SO_4, it is split up into iso-dulcite and naringenin, the latter being precipitated from the solution as a white crystalline mass. Purified by recrystallisation out of alcohol, naringenin melts at 248°, when decomposition sets in. It possesses the weak acid properties of a phenol, dissolves readily in solutions of the alkalis but forms no salts with alkaline carbonates. With ferric chloride it forms a deep red-brown coloured solution and it dissolves readily in alcohol, ether and benzene. The analyses agree with the formula $C_{15}H_{12}O_5$. The iso-dulcite obtained by the decomposition of naringin agreed in all its properties with the published descriptions of it. The specific rotatory power was found to be $[\alpha]_D = 8{\cdot}2°$.

Naringenin is readily decomposed when boiled with concentrated KHO, the products being phloroglucinol and naringeninic acid. The phloroglucinol agreed in properties with descriptions already published. It melted at 209° and crystallised in the prismatic system. The naringeninic acid was separated from the phloroglucinol by precipitation with dilute H_2SO_4, filtered, dissolved in $NaHCO_3$ solution, again filtered and precipitated with H_2SO_4. Thus obtained it is crystalline and may be purified by recrystallisation from hot water. The analytical data agree with the formula $C_9H_8O_3$. From hot water it crystallises anhydrous, while from cold water it crystallises in long shining needles containing 1 molecule of H_2O. It melts at 207° and gives a red-brown coloured solution with ferric chloride. If the aqueous solution be treated with sodium amalgam, hydronaringeninic acid ($C_9H_{10}O_3$) is formed, melting at 126°. To naringin may be assigned the formula $HO.C_6H_4.CH{:}CH.CO.O.C_6H_3(OH)_2[HO{:}CH=1{:}4$ and $O{:}OH{:}OH=1{:}3{:}5]$. Naringin must be considered to be a glucoside composed of naringenin in combination with iso-dulcite.—J. W. L.

Optical Behaviour of Cocaïne and a Method for Proving its Purity. O. Antrick. Ber. **20**, 310—322.

IN order to place in the hands of chemists a method for the accurate estimation of cocaïne hydrochloride, the author has determined the specific rotation of solutions of this salt obtained from different sources in as pure a state as possible. All the specimens which the author examined dissolved in water with a slight turbidity, and he therefore used diluted alcohol as the solvent. The instrument he used for the determination of the power of rotation was a Landolt's polaristrobometer (*Zeits. f. Instrumentenkunde*, 1883, 121). For the determination of the sp. gr., as well as the strength of the solution, the author used a flask of the form in the accompanying wood-cut. The bulb A has a capacity of about 25cc., and



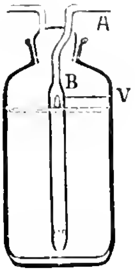
in preparing a solution it is filled up to the mark *b*, the diameter of the neck here being 5mm. The sp. gr. was taken at 20°, water at 4° being the unit of comparison. For the calculation of the constants A and B in the formula $[\alpha]_D = A + Bq$, and $[\alpha]_D = A - Bc$, a specimen of cocaine hydrochloride obtained from Messrs. Jaffé and Darmstaedter was taken as the standard. This specimen not only answered all the requirements of the Pharmaceutical Commission of the Society of Apothecaries, but the analytical data also agreed with those obtained by other authors. It melted at 181·5°. Tables are given with details of results obtained.

In using this method for the examination of any specimen of cocaine hydrochloride, the author suggests that the flask he used will be found very useful, and advises that 100cc. of the solution shall contain 10 or 20grms. of the salt, and further that more than one determination shall be made, and a mean of the results taken.—J. W. L.

XXII.—GENERAL ANALYTICAL CHEMISTRY.

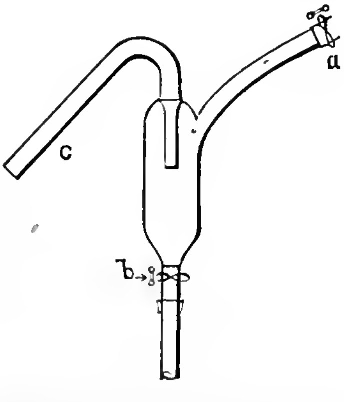
Drechsel's Absorption Bottle with Valve. Chem. Zeit. **11**, 224.

The bottle has inside the gas-inlet tube A a small valve light enough to float upon liquors. If gas be passed into A, the valve will allow it to enter, but as soon as the pressure diminishes the valve will rise, close tube A at B and thus prevent the flowing back of the liquor. —S. H.



A New Siphon. A. Jolles. Rep. Anal. Chem. **7**, 151.

By sucking slightly at *a*, and then closing the pinch-cock, a partial vacuum is created in the body of the apparatus, which is at once filled with the liquid rising through the tube *c*. On opening the pinch-cock *b*, the apparatus acts like any ordinary siphon. It is extremely easy to set the siphon in action and none of the liquid can be drawn into the mouth of the operator, so the apparatus is specially recommended for siphoning poisonous liquids.—E. E. B.



A Method of Maintaining Water-baths, Spirit-lamps, etc., at a Constant Level. R. Bensemann. Rep. Anal. Chem. **7**, 3 and 4.

Fig. 1 shows the arrangement recommended. F is the bottle from which the liquid is supplied. The level of the liquid in the spirit lamp or water-bath B is determined by the regulator A, which is a cylindrical vessel, provided with a doubly-bored cork and two tubes. A is partly filled with mercury, into which the longer of the two tubes dips; and the level of the liquid in B can be altered by changing the depth to which the tube dips into the mercury. In order to start the apparatus, the tube is raised out of the mercury until the liquid begins to flow out of F, and when it has reached the desired level, the tube is again pushed down into the mercury until the flow is checked. The level in B then remains constant, the condition for equilibrium being $h = q \pm s$, where *h*, *q*, and *s* denote the respective pressures due to the columns of liquid so marked in the figure. A still simpler arrangement is to omit A altogether, and connect B directly with F, as in Fig. 2. The level of the liquid in B is then regulated by varying the depth to which the vertical tube dips into the liquid in F. The apparatus is put into working order by blowing air in through this tube until the liquid has reached the proper level in B. The cork shown in the neck of B need not be air-tight, as it only serves to support the tube which conveys the liquid.—D. E. J.

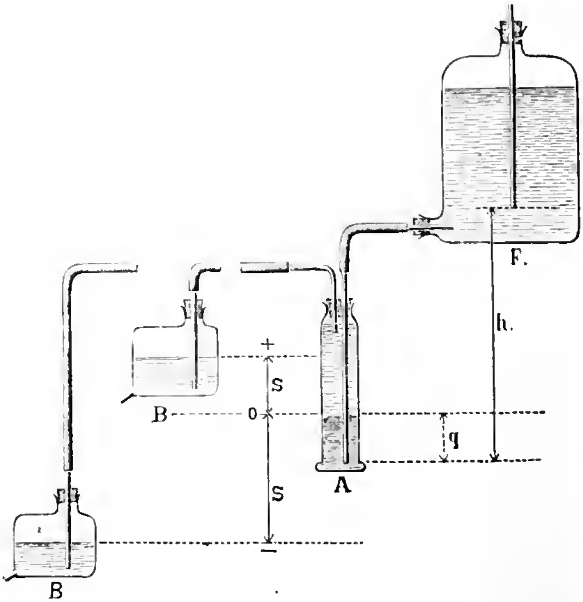


Fig. 1.

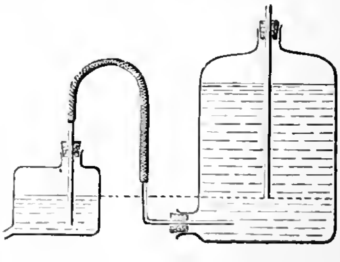

Fig. 2.

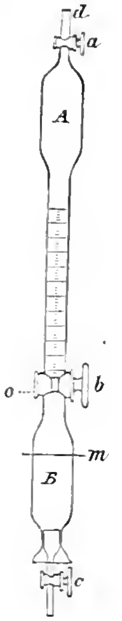
A New Gas Burette. B. Franke. J. Prakt. Chem. **35**, 1887, 259—262.

The burette consists of a measuring tube A and the bulb B for holding the reagents, connected by a tap *b*. The other end of B can be closed by a stopper with a tap c. The measuring tube A holds exactly 100cc., the zero of the scale lying in the bore of the tap *b*. The burette is filled with the gas to be examined either by passing it through the apparatus for some time or by filling the burette with water and aspirating the gas through *d* until the level of the water has sunk to *m*. The tap *a* is then closed, and the burette placed vertically in water, so that the water inside and outside is on the same level. On closing *b*, the gas in the burette is under the ordinary atmospheric pressure.



The vessel B is filled with any absorbing agent for treating the gas, and the stopper inserted afterwards. The tap *c* is closed and *b* opened, so that the liquid may enter the measuring tube to be thoroughly mixed with the gas by shaking. After the absorption has taken place, the liquid is again collected in B, *b* is closed, and after rinsing and filling B with water, the burette is placed in water. The tap *b* is then opened in order to measure the gas under the same conditions as before. It will be seen that the burette is of general application, like Bunte's, and can also replace the more expensive Orsat's apparatus.—S. H.

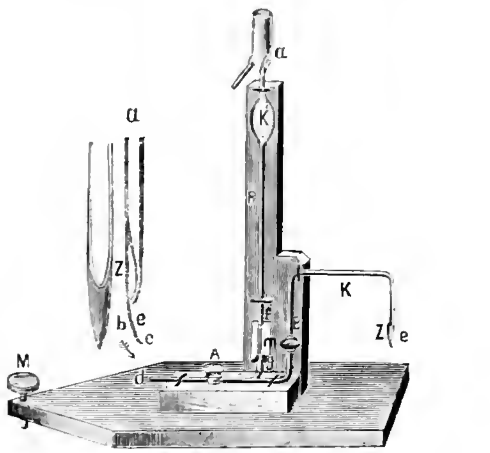
Pipettes without Graduations. A. Beutel and F. W. Dafert. Rep. Anal. Chem. **7**, 186—190.

THE advantages claimed for this form of pipette, which consists of a siphon arrangement by means of which a constant volume of liquid is allowed to pass from one part of the apparatus to another, are, that it requires no manipulative skill, while it is, at the same time, quite as accurate as any of the ordinary measuring instruments employed in volumetric work. Indeed, a comparison made with both pipettes and burettes, by weighing the amounts of water delivered, seems to show that this new form is more accurate than burettes and quite as accurate as any form of pipette.

The liquid to be measured enters the apparatus by the tube *d* (Fig. 2) which is connected with the supply vessel (not shown in the figure). The pipette is filled by opening the stopcocks A and B, and allowing the liquid to flow in until the siphon K is full. B is now closed, and then A. Any liquid rising in the tube *f* K′ above the level of *a* is carried away by the overflow pipe (see Fig. 2). The tube *f* K′ is 5—6mm. wide, and by making it of considerable length and having the bulb K′ at the top, the liquid in K is under sufficient pressure to enable it to flow out rapidly. The portion of the tube *fg* is narrowed (internal diameter 2—2½mm.) in order to reduce the fluctuations of the meniscus of the fluid to a minimum. There is a mark at *m*, and the pipette is in the correct position, when on emptying the siphon the meniscus of the fluid rests at this point. The pipette is fixed on a wooden board, and all corrections for position are made by the screw M. By means of this screw any difference in the capillarity of the liquids used, is readily allowed for: the meniscus must be at *m* when the siphon is empty.

The pipette having been filled as described, the mode of operations is as follows:—The stopcock B is opened and the liquid in *f* K′ sinks to *m*. To avoid any inaccuracy in the manner in which the contents of the siphon are delivered, a glass tongue *z* is fixed on to *e* (Fig. 1), and as soon as more liquid drops from Z, B is closed, and the vessel receiving the liquid moved along the tongue Z in the direction indicated by the arrow (Fig. 1). The pipette is refilled on opening A, and is again ready for use. It is necessary to pay particular attention to closing B at the right moment, and also to the manner in which the last drops of liquid are removed from *z*. With these points duly observed, and provided there is no change in temperature, the volume of liquid flowing from *e* is constant.

FIG. 1. FIG. 2.



The glass stopcocks A and B may be replaced by indiarubber tubing connections and pinchcocks. The tubing used must be as near as possible of the same bore as the tubes, and some arrangement must be introduced for fixing the siphon K securely.—C. A. K.

Pesier's Natrometer. E. Pfeiffer. Chem. Zeit. **11**, 443.

PESIER'S natrometer was first introduced in 1846 for the valuation of potash in the residues obtained from the calcination of beetroot molasses, and it was soon abandoned for the better method of determining potash by platinum chloride. The author states that in the hands of a careful analyst, the natrometer gives with little trouble results well agreeing with those obtained by the platinum method. The apparatus consists of a hydrometer, the scale of which is based on the fact that the density of a potassium sulphate solution increases proportionately with the amount of solid matter in solution. If the solution contains sodium sulphate, the density rises considerably, potassium sulphate being more soluble in the presence of sodium sulphate. For further details as to the precautions to be observed, the original paper should be consulted.—S. H.

Scheme for the Detection of Artificial Colouring Matters. E. Weingärtner. Chem. Zeit. 1887, 135—137 and 165—169.

IT is of considerable importance to the dyer or printer to be able to identify by readily performed tests, the dyestuffs he is using, as colouring matters that have been long known, and mixtures of these, are often sold under new names. Upon the scheme proposed by Witt (this Journal, 1886, 249) the author has based a complete system of qualitative analysis for all the dyestuffs at present occurring in the market. This has been successfully used for six months in the laboratory of the Ecole de Chemiè, at Mülhausen. Before proceeding to the analysis it is necessary to first determine whether the substance is a simple compound or a mixture of dyestuffs, since the presence of more than a small quantity of a second colouring matter would obscure the reactions and lead to erroneous conclusions. In the case of mechanical mixtures this can usually be ascertained by sprinkling a little of the powder upon filter-paper and moistening with water or alcohol, when streaks of the constituent colours will be seen. Mixtures of azo-

DYESTUFFS SOLUBLE IN WATER.

A. *Precipitated by Tannin Basic Colours.*—The aqueous solution is reduced with zinc-dust and HCl, neutralised and a drop put on filter-paper:—

THE ORIGINAL COLOUR REAPPEARS					THE ORIGINAL COLOUR DOES NOT APPEAR.
Red.	Yellow and Orange.	Green.	Blue.	Violet.	Yellow, Brown, and Blue.
Magenta	Phosphine	Malachite green	Methylene blue	Methyl violet	Chrysoidine
Toluylene red	Flavoaniline	Brilliant green	New blue	Hofmann violet	Bismarck brown
Safranine		Methyl green	Muscarine	Mauveine	Auramine
				Amethyst	Victoria blue
				Crystal violet.	

B. *Not Precipitated by Tannin—Acid Colours.*—Reduced with zinc-dust and HCl (or zinc-dust and ammonia).

On Paper the original Colour reappears. The Aqueous Solution is acidified with HCl and extracted with Ether.		The original Colour does not reappear. The Dyestuff is heated on Platinum Foil.			The Colour is changed to a Brownish-red. On Paper the original Colour of the Ammoniacal Solution is restored.
The Ether dissolves the Dyestuff and the Aqueous Solution is left nearly colourless.	The Ether remains uncoloured.	Deflagrates without production of Coloured Vapours.	Burns with production of Coloured Vapours. A piece of unmordanted Cotton is heated in the Aqueous Solution.		
			The Colour on the Cotton resists a warm Soap-bath.	The Colour is stripped by a warm Soap-bath.	
Phthaleïns	Sulphonated rosaniline derivatives	Nitro-colouring matters	Benzidine colours	Azo-colouring matters	Alizarin S
	Sulphonated indulines		Erythrosine		Alizarin blue S
					Cœruleïn S

DYESTUFFS INSOLUBLE IN WATER.

The colouring matter is treated with water and a few drops of 5% caustic soda.

It dissolves. The Alkaline Solution is heated with zinc-dust and a drop put on filter-paper.		It remains undissolved. The Dyestuff is heated with 70% Alcohol.				
The Colour reappears.	The Colour does not reappear of the same shade, or the original Colour remains unaltered.	Soluble.				Not soluble.
		Solution not Fluorescent.		Solution Fluorescent.		
		Caustic Soda (33%) is added.				
		Colour becomes reddish brown.	No alteration in Colour.	The Fluorescence is destroyed.	The Fluorescence remains.	
Cœruleïn	Canarine	Induline	Indophenol	Magdala red	Primrose	Indigo.
Galleïn	Alizarin	Nigrosine			Cyanosine	
Gallocyanine	Anthrapurpurine	Rosaniline blue (opal)				
Galloflavine	Nitro-alizarin	Diphenylamine blue (opal)				
	Alizarin brown					
	Alizarin blue					
	Chrysamine					
	Solid green					

colours which do not differ widely in shade and hence are not readily seen by the above test, are rendered apparent by scattering a few particles of the colour upon the surface of concentrated H_2SO_4 contained in a white porcelain dish.

When the constituents of the mixture have been precipitated together, fractional dyeing must be resorted to; a bath of the colour is prepared and a number of pieces of wool or silk are dyed from it in succession until exhausted; if a great difference in shade is apparent between the first and last dyeings the substance is not a single compound.

The commonest impurities are salt, sodium sulphate, sodium carbonate, and dextrin. *Salt* is detected by igniting and testing the residue for chlorine. *Sodium sulphate* remains in the filtrate after precipitating the colour with pure sodium chloride, and is indicated by barium chloride. *Dextrin* is readily recognised by its smell and by its remaining undissolved when the colouring matter is extracted with alcohol.

The author employs a solution of tannin to distinguish acid from basic colours, the two groups being further subdivided by their behaviour on reduction with zinc dust and HCl. The tannin reagent is made by dissolving 25grms. of tannin and 25grms. of sodium acetate in 250cc. of water. If a few drops of this reagent (an excess must be avoided) is added to the solution of the dyestuff and the solution heated, all basic colours are precipitated; acid colours are not precipitated (if the solution is hot).

BASIC COLOURS.

Red.

(*a*) Bluish red in aqueous solution turned yellowish brown by HCl or H_2SO_4.—*Magenta* (roseine, fuchsine, etc).

(*b*) Bluish red in aqueous solution; ammonia precipitated brown flocks soluble in ether with a greenish yellow fluorescence. Dissolves in HCl with a blue colour, in concentrated H_2SO_4 with a green; on dilution the colour changes through blue and violet to red.—*Neutral red.*

(*c*) Addition of alcohol to the aqueous solution causes an orange fluorescence. Dissolves in concentrated H_2SO_4 with a green colour, which on dilution changes through blue and violet into red.—*Safranine.*

Yellow.

(*a*) Alkalis give a flocculent yellow precipitate, which is soluble in ether with a yellow colour and strong green fluorescence.—*Phosphine.*

(*b*) Alkalis give a yellowish white precipitate, soluble in ether, without colouration, with a splendid blue fluorescence.—*Flavaniline.*

Green.

(*a*) Turned yellow by acid. Alkalis throw down a pink or grey precipitate.—*Malachite green.*

(*b*) Ammonia gives no precipitate. Dissolves in H_2SO_4 with a yellow colour, becoming green on dilution.—*Brilliant green.*

(*c*) The aqueous solution has a blue or greenish blue colour; turned yellow by acids; discolourised by alkalis without forming a precipitate.—*Methyl green.*

Violet.

(*a*) Very soluble in water; alkalis produce a violet brown precipitate. The solution is turned yellow by H_2SO_4 and on dilution the colour changes through green into bluish violet.—*Methyl violet* and *Hofmann violet.*

(*b*) Highly soluble in cold water; HCl changes the colour to blue; alkalis give a brown precipitate. H_2SO_4 gives a dirty violet colour, which becomes blue and finally violet on dilution.—*Neutral violet.*

(*c*) Moderately soluble in water; alkalis give a violet precipitate; H_2SO_4 changes the colour to grey, on dilution the colour passes through sky blue into reddish violet.—*Mauvein.*

(*d*) Soluble in water with a reddish violet colour; addition of alcohol produces a red fluorescence, H_2SO_4 produces a green colour, which on dilution changes through blue into violet.—*Amethyst.*

(*e*) Caustic soda gives a yellow precipitate; addition of HCl or H_2SO_4 changes the colour to orange. Long six-sided crystals.—*Crystal violet.*

Blue.

(*a*) The concentrated solution gives a violet black precipitate with NaOH. Coloured grass-green by H_2SO_4. Contains zinc.—*Methylene blue.*

(*b*) The aqueous solution is bluish violet; NaOH gives a brownish black precipitate. Concentrated H_2SO_4 gives a green colour, on dilution passing through blue into violet.—*Neublau* (Casella).

(*c*) Sparingly soluble in cold water, easily in hot, with a violet colour; NaOH gives a reddish brown precipitate. Tannin gives an indigo blue precipitate. Dissolves in concentrated H_2SO_4 with a bluish green colour, on dilution becoming blue and then violet.—*Muscarine.*

Brown, Yellow and Blue.

(*a*) Soluble with a yellow colour; alkalis give a white precipitate, which is soluble in ether without fluorescence; boiling with dilute H_2SO_4 slowly decolourises the solution. Reduction with zinc-dust and acetic acid gives an evanescent green colouration.—*Auramine.*

(*b*) Dyes wool orange yellow. Dissolves in concentrated H_2SO_4 with a yellowish brown colour.—*Chrysoidine.*

(*c*) Dyes wool orange brown. Dissolves in concentrated H_2SO_4 with a brown colour.—*Bismarck brown.*

(*d*) Acids turn the solution yellowish brown; alkalis give a brownish red precipitate. Dissolves in H_2SO_4 with a reddish brown colour, which becomes greenish blue on dilution.—*Victoria blue.*

ACID COLOURS.

Phthaleins.

(*a*) The aqueous solution is red with a greenish fluorescence; acids produce an orange precipitate which is soluble in ether with a yellow colour. Dissolves in concentrated H_2SO_4 yellow; on heating, fumes of HBr are evolved; if manganese dioxide is added bromine is liberated.—*Eosin.*

(*b*) The aqueous solution is more bluish-red than eosin; acids produce a yellowish brown precipitate, which is soluble in ether with a yellow colour. Reacts with H_2SO_4 same as eosin. Heated on platinum foil it burns with production of "Pharaoh's serpents."—*Safrosin* (Eosin scarlet).

(*c*) Bluish red solution with slight greenish fluorescence; acids produce a flesh-coloured precipitate soluble in ether with a brownish yellow colour. Reactions with H_2SO_4 same as eosin.—*Phloxin.*

(*d*) The aqueous solution is dark bluish red without fluorescence; acids give a red precipitate soluble in ether with an orange colour. The alcoholic solution has a golden-yellow fluorescence. Dissolves in concentrated H_2SO_4 with an orange colour; on heating, iodine is liberated.—*Rose Bengal.*

(*e*) Brownish yellow solution with strong green fluorescence; acids give a yellow precipitate.—*Uranin* and *Chrysolin.*

(*f*) Red solution smelling of phenol; acids give a yellow precipitate.—*Corallin* and *Aurin.*

Sulphonated Rosaniline Derivatives and Indulines.

(*a*) The aqueous solution is bluish-red; on heating with NaOH the colour vanishes but is restored by acetic acid. Dissolves in H_2SO_4 with a yellow colour, becoming red on dilution.—*Acid magenta.*

(*b*) Easily soluble in water with a slight greenish colouration; addition of a little acid intensifies the colour but an excess turns it yellow. Alkalis decolourise it.—*Helvetia green* (acid green).

(*c*) Alkalis decolourise it. Wool extracts the colour from the ammoniacal solution, and after washing and developing in dilute acid, becomes deep blue.—*Alkali blue.*

(*d*) Easily soluble and crystallises in metallic glistening flakes. Wool is only dyed from an acid bath.—*Soluble blue (China blue).*

(*e*) The violet aqueous solution is decolourised by ammonia without precipitation. Coloured orange by H_2SO_4, on dilution changing through green and blue to violet.—*Acid violet.*

(*f*) The colour of the aqueous solution varies between bluish grey and reddish grey; alkalis redden it; acids give a bluish or violet precipitate. Not decolourised by heating with dilute nitric acid.—*Indulines* and *nigrosines.*

Nitro Colouring Matters.

(*a*) Greenish-yellow solution. Bitter taste. The alkaline solution is not precipitated by HCl. The alkaline salts deflagrate.—*Picric acid.*

(*b*) Golden-yellow solution; HCl gives a light yellow precipitate, soluble in ether.—*Naphthol yellow* (primrose).

(*c*) Golden-yellow solution; HCl gives no precipitate.—*Naphthol yellow S.*

(*d*) The concentrated aqueous solution is red, the dilute solution is yellow; excess of alkalis gives a dark-red precipitate; acids give a milky precipitate—*Aurantia.*

Benzidine Colours.

(*a*) The red aqueous solution is coloured blue by a trace of HCl. Dissolves in concentrated H_2SO_4 with a slate-blue colour not changed by dilution.—*Congo red.*

(*b*) The aqueous solution is orange-red; when concentrated, a brown precipitate is produced by concentrated H_2SO_4 or HCl, which, on dilution, dissolves to a brown solution.—*Benzopurpurin.*

(*c*) The bluish-violet solution is turned red by alkalis; when concentrated, HCl gives a violet precipitate. Dissolves in concentrated H_2SO_4 with a violet colour.—*Azo blue.*

Bluish-red solution; HCl and H_2SO_4 produce an orange precipitate. On heating, the solid iodine sublimes.—*Erythrosin.*

Azo Colouring Matters.

(*a*) The yellow aqueous solution gives a precipitate with $BaCl_2$ but not with $CaCl_2$. Dissolves in H_2SO_4 with a yellow colour, which, on dilution, becomes brownish-red and finally orange.—*Fast yellow.*

(*b*) The yellow aqueous solution deposits the dyestuff, on cooling, in crystals; with $BaCl_2$ and $CaCl_2$ it gives crystalline precipitates. Dissolves in H_2SO_4 with a violet colour, reddish-violet on dilution.—*Diphenylamine yellow* (Tropæoline O O).

(*c*) Deflagrates on heating with formation of "Pharaoh's serpent" and evolution of yellow vapours. Dissolves in H_2SO_4 with a carmine-red colour, becoming yellow on dilution. The reduced dyestuff put on filter-paper forms brown spots.—*Indian yellow* (citronine).

(*d*) The orange aqueous solution is coloured violet by HCl; $BaCl_2$ gives a precipitate but not $CaCl_2$. Dissolves in H_2SO_4 with a violet-red colour, which becomes red on dilution.—*Azoflavine.*

(*e*) The yellow aqueous solution, on cooling, deposits the dyestuff in yellow plates; dilute acids precipitate reddish-violet plates. Dissolves in concentrated H_2SO_4 with a yellow colour, becoming red on dilution.—*Methyl or Ethyl orange.*

(*f*) The aqueous solution is yellow; on cooling, the dyestuff crystallises out. Sulphuric acid changes the colour to bluish-green, on dilution becoming violet and forming a slate-blue precipitate. Barium chloride gives a yellow precipitate.—*Yellow N* (Poirrier).

(*g*) The aqueous solution is yellow: on cooling, the dyestuff crystallises out. Dissolves in H_2SO_4 with a yellowish-green colour, on dilution becoming violet with a grey precipitate. Calcium chloride gives an orange precipitate, which, on heating, becomes red and crystalline.—*Luteoline.*

(*h*) Forms a well crystallised calcium salt. Dissolves in H_2SO_4 with a dark orange colour, not changed on dilution.—*Orange G.*

(*i*) The addition of a trace of HCl to the yellow solution produces a crystallisation of yellow plates; a larger quantity precipitates grey needles. The solution in H_2SO_4 is brownish-orange, not changed by dilution.—*Tropæoline O* (chrysoïne).

(*j*) The reddish-orange solution gives precipitates with $BaCl_2$ and $CaCl_2$: the calcium salt crystallises from a large quantity of water in red needles. Dissolves in H_2SO_4 with a carmine-red colour, giving an orange precipitate on dilution.—*Orange II.* (Mandarine).

(*k*) The aqueous solution is reddish-orange, turned carmine-red by NaOH. Dissolves in H_2SO_4 with a violet colour, giving, on dilution, a brown precipitate and then an orange solution.—*Orange I.* (tropæoline OOO).

(*l*) The orange aqueous solution deposits on cooling a yellow precipitate; $BaCl_2$ gives a precipitate, but not $CaCl_2$. The H_2SO_4 solution is yellow.—*Tartrazine.*

(*m*) The orange aqueous solution gives a precipitate with $BaCl_2$. The H_2SO_4 solution is dull violet, becoming red on dilution.—*Metanil yellow.*

(*n*) The concentrated aqueous solution gelatinises on cooling. Dissolves in concentrated H_2SO_4 with a green colour, which becomes bluish-violet on dilution.—*Biebrich scarlet.*

(*o*) Calcium chloride gives a red precipitate. Solution in H_2SO_4 blue, on dilution passing through violet into red.—*Croceine scarlet.*

(*p*) The aqueous solution deposits bronzy crystals on cooling. Solution in H_2SO_4 violet, on dilution a brown precipitate.—*Ponceau from xylidine and α-naphthol-sulphonic acid.*

(*q*) The red aqueous solution is turned reddish-brown by NH_3; $BaCl_2$ gives a brown precipitate. Solution in H_2SO_4 magenta-red, red on dilution.—*Coccine* and *Coccinine.*

(*r*) The aqueous solution is brownish-red; when concentrated, the addition of a few drops of Na_2CO_3 causes the separation of brown glistening plates. The solution in H_2SO_4 is violet, becoming red on dilution.—*Roccelline.*

(*s*) The red aqueous solution gives a precipitate with $BaCl_2$. Solution in H_2SO_4 indigo-blue, red on dilution.—*Bordeaux G and R.*

(*t*) The aqueous solution is turned dark violet-red by NH_3. Solution in H_2SO_4 blue, on dilution passing through violet to red.—*Ponceau S.*

Anthracene Colours.

(*a*) The aqueous solution is brownish-yellow; with HCl, pure yellow; strong solutions give a violet precipitate with NaOH, a red precipitate with $CaCl_2$. Solution in concentrated H_2SO_4, yellow.—*Alizarin S.*

(*b*) The olive-brown aqueous solution is turned green by NH_3. The solution, obtained by reduction with zinc dust and NH_3, quickly oxidises in the air with production of a green precipitate.—*Cœrulein S.*

(*c*) The brownish-red aqueous solution is turned greenish-blue by NH_3, green by NaOH. The HCl solution is yellowish-orange. The reduced solution quickly oxidises with production of a blue precipitate.—*Alizarin blue S.*

COLOURING MATTERS INSOLUBLE IN WATER.

(*a*) The NaOH solution is violet. Solution in H_2SO_4 is blue.—*Gallocyanine.*

(*b*) The solution in strong aqueous NaOH is indigo-blue, on dilution violet-red. The H_2SO_4 solution is orange.—*Galleïn.*

(*c*) The NaOH and concentrated H_2SO_4 solutions are green.—*Cœruleïn.*

(*d*) The NaOH solution is dull yellow. Dissolves in concentrated H_2SO_4 with a yellow colour.—*Galloflavin.*

(*e*) The NaOH solution is yellow. Unmordanted cotton is dyed a fast yellow from an alkaline bath. Insoluble in concentrated H_2SO_4.—*Canarine.*

(*f*) The NaOH solution is bluish-violet; addition of zinc-dust to the cold bath changes the colour to red.—*Alizarin.*

(*g*) The NaOH solution is magenta-red. Reactions like alizarin.—*Anthrapurpurin* and *flavopurpurin.*

(*h*) The NaOH solution is orange. Dissolves in H_2SO_4 with a magenta-red colour, brown precipitate on dilution. Dyes unmordanted cotton.—*Chrysamine.*

(*i*) The NaOH solution is red: on reduction with zinc-dust it gives, on filter paper, indigo-blue spots. *Nitro-alizarin.*

(*j*) The NaOH solution is olive: after reduction it forms dull violet spots on filter-paper. Solution in H_2SO_4 brownish-red. *Alizarin maroon.*

(*k*) Sparingly soluble in NaOH with a green colour: the reduced solution forms dark blue spots on filter paper. *Alizarin blue.*

(*l*) The alcoholic solution is bluish-grey to reddish-grey.—*Indulines* and *nigrosines.*

(*m*) The alcoholic solution is deep blue: addition of NaOH turns it brown, HCl turns it greener. The H_2SO_4 solution is reddish-brown.—*Rosaniline* or *diphenylamine blue.*

(*n*) The blue alcoholic solution is turned brownish-red by HCl.—*Indophenol.*

(*o*) The alcoholic solution is bluish-red with red fluorescence.—*Magdala red.*

(*p*) The alcoholic solution is bluish-red with greenish-yellow fluorescence; addition of HCl turns it yellow and the fluorescence vanishes.—*Methyleosin.*

(*q*) The alcoholic solution is bluish-red with a red fluorescence; addition of HCl turns it orange and the fluorescence vanishes.—*Cyanosin.*

(*r*) The powder, reduced with zinc-dust and NH gives a yellow solution, which forms blue spots on filter-paper.—*Indigo.*—A. G. G.

Colour Reactions of Beetroot Sugar. A. Ihl. Chem. Zeit. **11**, 2.

SUGAR treated with dilute sulphuric or hydrochloric acid yields ulmous substances, which give very characteristic reactions with phenols. If a rather concentrated solution of beetroot sugar be boiled with a small quantity of hydrochloric or sulphuric acid, a solution of resorcinol added to the cooled liquid and afterwards gradually plenty of hydrochloric acid, an eosin-red colouration is produced, which soon increases, until at last a precipitate of red flakes is obtained. Concentrated sulphuric acid has a similar effect if the temperature does not rise too high. Caramel solutions give the same reactions with resorcinol and hydrochloric or sulphuric acid, and it may be concluded that caramel splits up into the same compounds as beetroot sugar. The ulmous substances also react with all the other phenols. Pyrogallic acid acts similarly to resorcinol, but the precipitate is brown-red. Orcinol requires the presence of alcohol for a characteristic reaction. If a sugar solution be boiled with an alcoholic orcinol solution and concentrated hydrochloric acid, a dark-yellow liquid is obtained, which, poured into water, yields a brilliant green precipitate. α-Naphthol in alcoholic solution gives, with sugar and acid, a violet-red colouration, which, according to Molisch, allows of the detection of 0.00001 per cent. of sugar. If a piece of sugar be moistened with an aqueous solution of resorcinol, and then with concentrated sulphuric acid, the sugar is coloured dark-red; an alcoholic solution of α-naphthol colours the sugar, in a similar manner, blue-violet. White thymol, cresol and guaiacol produce a red colouration. If sugar be treated with alcohol, diphenylamine and sulphuric acid, a blue dyestuff is obtained.—S. H.

Estimation of Organic Matter in Spring Water. A. Köbrich. Chem. Zeit. **11**, 4.

THE detailed statement of every analysis of water contains an item for organic matter, to which little practical value can be given, so long as no uniform method of testing is adopted. The author recommends the following process, which gives very concordant results. It is based upon the decomposition of organic matter by potassium permanganate and sulphuric acid at an elevated temperature. 0.5grm. of the permanganate is dissolved in 1 litre of water, to which 150grms. of pure concentrated sulphuric acid are added. This mixture is heated at 90° C. for three hours in a flask with a long neck, without replacing the water which evaporates, and then titrated with a standard oxalic acid solution containing 0.5grm. of oxalic acid per litre. 100cc. of the water to be tested are then mixed with 50cc. of the permanganate solution and 15cc. sulphuric acid, and the mixture is heated at 90° C. for three hours in a covered flask, which allows of the escape of steam. The unreduced permanganate is titrated back with the standard oxalic acid. The author suggests, for analytical purposes, that the amount of organic matter thus found should be calculated in equivalents of oxalic acid. If chlorine be present in the water, it must be removed with silver before treating with permanganate. If nitrous acid is also present, the filtrate from the silver chloride precipitate is acidified with sulphuric acid, and permanganate added drop by drop until the pink colour remains permanent for at least five minutes. More sulphuric acid is then added, and the organic matter determined as previously mentioned. Nitrous acid reduces a permanganate solution at once and in the cold, whereas organic matter requires both time and heat for the reduction.—S. H.

Estimation of the Amount of Cinchonidine in Officinal Quinine Sulphate. F. Jobst. Chem. Zeit. **10**, 1617—1618.

THE author contends that De Vrij's "bisulphate test" is not suited as a means of testing the proportion of cinchonidine in quinine sulphate, the results being about 61 per cent. above the truth. This is due to the fact that in this test ether fails to separate cinchonidine as such, a compound of cinchonidine and quinine of the constitution $C_{20}H_{24}N_2O_2.2C_{19}H_{22}N_2O$ being obtained. The author is of opinion that the existing apprehensions concerning the high amount of cinchonidine in officinal quinine sulphate are largely exaggerated, as they are based on imperfect tests.—D. B.

Valuation of Commercial Indigo. T. Manoley. Romen's Journal, 1887, 16.

THE author employs the method of Fritzsche in the following way:—About 1grm. of the finely-powdered indigo is moistened with a little strong alcohol in a half-litre cylinder. 2—3grms. of clear glucose syrup diluted with a little water is poured into 100cc. of strong alcohol and treated with a few centimetres of NaOH. The fine emulsion thus obtained is added to the indigo, the cylinder filled up with boiling strong alcohol and closed with a stopper provided with two tubes like a wash-bottle. After standing for 24 hours with repeated shaking, the fluid is blown into dilute H_2SO_4, left standing for two days, filtered through a weighed filter, dried and weighed. The employment of hydrogen peroxide as an oxidising agent is recommended, as the tendency of the precipitate to stick to the walls of the vessel is thereby avoided (this Journal, 1884, 319 and 516; *Dingl. Polyt. J.* **256**, 175; **258**, 364).—A. G. G.

Estimation of Indigo on the Fabric. A. Renard. Bull. Soc. Chim., 1887, [47], 41.

THE material is warmed in a flask at 60°—70° C. with a solution containing sodium hydrosulphite and lime. This is prepared by adding 100cc. of milk of lime to 100cc. of a solution of sodium hydrosulphite, obtained by reducing sodium bisulphite solution of 30° B., the mixture being diluted to two litres. A stream of coal-gas is led through the liquid in the flask and when the reduction of the indigo is complete, the solution is decanted into a graduated cylinder also filled with coal-gas; the volume should amount to about 100cc. The solution is precipitated with HCl and allowed to stand in the air for 12 hours. The filtered, washed and dried precipitate is then dissolved in 100cc. of fuming H_2SO_4 and the indigo titrated according to the method of A. Müller (*Jahresbericht f. Chem.* 1874, 1019).
—A. G. G.

Catalytic Actions. O. Loew. Ber. **20**, 144—145.

A 15 per cent. solution of formaldehyde treated with a concentrated solution of caustic soda yields formic acid (sodium formate) and methyl alcohol, there being only a very slight evolution of gas on warming the mixture and none at all in the cold. But if cuprous oxide be added a violent evolution of hydrogen ensues after 1–2 minutes, the solution becomes slightly warm and sodium formate is formed,

$$H.COH + NaOH = H.CO.ONa + H_2.$$

This result is not obtained with any other metallic oxides. In this reaction, according to the author, metallic copper in an extremely finely divided state is first formed, which owing to a "specific vibratory condition," modifies the reaction between caustic soda and formaldehyde. Copper dust and platinum black have a similar though far weaker action. A further catalytic action is that of platinum black on a caustic-soda solution of hydroxylamine, when the decomposition into nitrogen, ammonia and water takes place very readily. In absence of platinum black it is only slowly effected.—C. A. K.

The Action of Hydrogen Peroxide on Bismuth Oxyhydrate and Bismuthic Acid—A new Colour Reaction for Bismuth. K. Hasebroek. Ber. **20**, 213.

By the addition of a weak alkaline solution of hydrogen peroxide to bismuth subnitrate the white nitrate is converted, on warming, into a yellow-brown body; a rapid evolution of oxygen from the decomposed hydrogen peroxide taking place. The product is prepared on the large scale by adding commercial hydrogen peroxide to a dilute nitric acid solution of "magisterium bismuthii," and filtering into concentrated solution of ammonia, when the orange-yellow precipitate forms at once. The precipitate is then washed first with ammonia and then water, and dried in vacuo over sulphuric acid. It is light orange-yellow in colour, amorphous, and melts on heating to form crystalline bismuth oxide. It is insoluble in water, becomes brown on boiling with alkalis, and is soluble in dilute mineral acids. The body seems to be a higher oxide of bismuth, as it evolves oxygen on treatment with sulphuric acid, and chlorine when acted upon by hydrochloric acid. The analyses differ among themselves, but from these and the fact that hydrogen determinations show presence of hydroxyl groups, it is probable that the product is in reality a mixture of bismuth pentoxide and the carbonate; this latter being derived from the carbon dioxide of the air. By excluding the air during the preparation almost pure bismuth pentoxide, containing only traces of carbon dioxide, is obtained. As prepared by the Arppe-Hoffmann process—*i.e.*, oxidation by chlorine of an alkaline solution of bismuth trioxide—the pentoxide always contains potassium hydrate. The reaction also serves as a very delicate test for bismuth, and conversely for hydrogen peroxide; 1 part in 100,000 may be thus detected.—S. G. R.

Simple Method for the Generation of Chlorine from Bleach. C. Winkler. Ber. **20**, 184.

Dry bleach is intimately mixed with one-fourth its weight of burnt gypsum, moistened with cold water and ground in a mortar. The mixture is then placed in a shallow iron vessel and pressed to form a cake about half an inch in thickness. This is then cut up into cubes and dried at 20° C. It is used in an ordinary Kipp's apparatus. HCl of sp. gr. 1·124 mixed with an equal volume of water is employed to liberate the gas.—S. G. R.

On Weil's Method for the Volumetric Determination of Sulphuretted Hydrogen in Sulphides decomposable by Hydrochloric and Sulphuric Acids. C. Friedheim. Ber. **20**, 59.

In Weil's method the H_2S is passed into an excess of a standard ammoniacal copper solution and the excess of copper estimated by titration with stannous chloride. Pelouze and Raschig have, however, shown that, short of complete saturation, the copper sulphide always retains varying amounts of copper oxide, and their results are now confirmed by the author. By digesting the solution for a quarter of an hour at 90° C., both cuprous chloride and sulphuric acid were detected, formed probably according to the equation $CuS + 7\ CuCl_2 + 4\ H_2O = 4\ Cu_2\ Cl_2 + H_2SO_4 + 6HCl$. Another source of error lies in the fact that strong ammoniacal solutions dissolve varying quantities of copper sulphide. The method, therefore, is altogether unreliable.—S. G. R.

Decomposition of Stannous Chloride Solutions. E. Donath. Rep. Anal. Chem. **7**, 77.

It is well known that standard stannous chloride solutions will not keep, oxygen being absorbed with separation of a precipitate even in strongly acid solutions. The author recently analysed the precipitate, which in this particular case was transparent and gelatinous. He found it to contain 2·65 per cent. of chlorine, and he believes it to consist of a mixture of stannic hydrate with the chloro-stannic compound SnO.Cl.OH, described by Mallet (*Chem. News.* **26**, 262).—E. E. B.

Gravimetric Determination of Manganese. C. Meineke. Chem. Zeit. 1887, 137.

In the estimation of manganese by chlorate precipitation as MnO_2, it is essential in order to obtain accurate results that *cold* water should be used for dilution. If warm water is employed a certain amount of the manganese remains in solution at MnO, and the results obtained are too low.—A. G. G.

Determination of Manganese by Precipitation with Mercuric Oxide and Bromine. C. Meineke. Rep. Anal. Chem. **7**, 54—58 and 67—76.

Volhard has described a process for estimating manganese by adding nitric acid and mercuric oxide, boiling and then adding chlorine or bromine water. Manganese peroxide is thrown down and the manganese, after purification and ignition, is weighed as Mn_3O_4. The results are very accurate, but the author finds that the process is not available for the very dilute solutions obtained by him in the separation of iron and manganese. The addition of zinc nitrate to the solution, however, rendered the precipitation by the above treatment complete, but the resulting Mn_3O_4 was found to contain a small quantity of iron oxide and a trace of zinc oxide, even after boiling the precipitate with dilute nitric acid. The manganese can be determined volumetrically in the precipitated oxide, after boiling it with nitric acid and washing, by titration with a standard oxalic acid solution containing a certain proportion of hydrochloric acid. An excess of the oxalate should be added and the solution titrated back with standard permanganate after the addition of sulphuric acid and of some manganous sulphate. The hydrochloric acid is necessary to avoid precipitation of oxalate of mercury. Details are given of the method adopted for ascertaining the amount of manganese in iron, and it is pointed out however little nickel the iron may contain, it will be precipitated with the manganese peroxide, together with some zinc oxide. Hence, after weighing the impure Mn_3O_4, it must be re-dissolved in hydrochloric acid, and the amount of nickel and zinc determined by precipitation with sulphuretted hydrogen in an acetic acid solution in the usual way. The weight of the oxides of these two metals, together with any iron oxide, must be deducted from the total weight, the difference being pure Mn_3O_4. To avoid this tedious separation of nickel and zinc the author prefers to multiply by 0·95 the weight of the impure Mn_3O_4 after deduction of the iron oxide, as the proportion of impurity is practically constant.—E. E. B.

Estimation of Chromium in Chrome Ironstone. Ed. Donath. Dingl. Polyt. J. **263**, 245—246.

Chrome ironstone mixed with 5 parts of barium dioxide and most finely ground, is ignited for half-an-hour in a porcelain crucible over a Bunsen burner. The yellowish-green semi-fused mass thus obtained dissolves in dilute HCl and contains all the chromium, as chromic acid; if the fusion is made in a platinum crucible at a higher temperature, the product, although still quite soluble, contains some chromic oxide. The barium is thrown down with a very slight excess of sulphuric acid, the filtrate neutralised with sodium carbonate, and then run into a boiling solution of potassium permanganate and sodium carbonate. The excess of permanganate is next carefully removed by a little ferrous or manganous sulphate, the alkaline chromate solution filtered off and the chromic acid determined with iron in the usual way. —T. L. B.

A Volumetric Determination of Phosphoric Acid, especially suitable for the Analysis of Thomas-slag. Chem. Zeit. **11**, 193–195 and 223–224.

THE molybdic precipitate being soluble in ammonia, E. Thilo has based upon this fact a method from which the weight of the phosphoric acid can be calculated. The precipitate is dissolved in a known quantity of standard ammonia and the excess of the latter is titrated back with standard sulphuric acid until the blue colour of litmus is suddenly turned violet. Although the contrast between blue and violet is not very great, the change is said to be very distinct. The ammonia is empirically standardised upon a weighed quantity of pure and dry molybdic precipitate. In this method, silicic acid need not be removed before the precipitation of the phosphoric acid, as it does not influence the result. A. Isbert rejects Thilo's process, as he could not obtain results agreeing with each other. The "neutral" point is very indistinct both with litmus and other indicators, and the composition of the molybdic precipitate is variable, since it nearly always contains more or less uncombined molybdic acid which acts on ammonia. He therefore devised another process—viz., the determination of the ammonia in the molybdic precipitate by distillation with sodium hydrate and the calculation of the phosphoric acid therefrom. This process is said to give very satisfactory results.—S. H.

Presence of the Calcium Salt of Tetrobasic Phosphoric Acid in Thomas-slag. H. Otto. Chem. Zeit. **11**, 255.

THE ready extraction of the phosphoric acid from Thomas-slag by dilute acid, whilst the ordinary phosphates of calcium, aluminium and iron after ignition are nearly insoluble in dilute acids, would seem to indicate that the phosphoric acid is present in some new form. Hilgenstock was the first to suggest that it occurs as a tetrabasic calcium phosphate, $Ca_4P_2O_9$. The author has confirmed this supposition by the analysis of crystals of this compound which can be isolated from the slag. These were nearly colourless thin tubes which did not absorb CO_2. The numbers obtained on analysis closely correspond to the above formula. The compound is easily soluble in dilute sulphuric, hydrochloric, nitric, citric and acetic acids. Although the pure compound is readily soluble in alkaline and neutral ammonium citrate solution, it cannot be completely extracted from the slag by these solvents, since the presence of the other constituents prevents complete solution. The extraction, however, can be effected by the employment of 1000cc. of the slightly acid dilute ammonium citrate solution of P. Wagner to 2½—3 grains of finely-ground slag. The following is an analysis of a sample of Thomas-slag:—

$Ca_4P_2O_9$	49·02 p. c.	FeO	8·06 p. c.
$CaSiO_3$	15·85 „	F_2O_3	5·14 „
CaO (free)	11·00 „	MgO	3·4 „
CaS	1·35 „	Al_2O_3	1·1 „
MnO	5·25 „		

—A. G. G.

Determination of the Phosphoric Acid in Basic Slags. G. Loges. Rep. Anal. Chem. **7**, 85—88.

THE solution of the phosphates in basic slags is usually effected by treating the slags with oxidising agents—*e.g.*, nitric acid, etc.—or with hydrochloric acid. Neither process is satisfactory, as in the former the whole of the phosphorus as iron phosphide is oxidised to phosphoric acid and afterwards estimated as such; and in the latter all the hydrochloric acid must be subsequently removed by evaporation with nitric acid before the phosphoric acid can be precipitated by the nitro-molybdate solution. Both the objections are overcome by the use of *concentrated sulphuric acid* as the solvent. The powdered sample is first mixed with enough dilute sulphuric acid (1 : 1) to combine with the calcium oxide and decompose the sulphides and carbonates, and then a large excess of concentrated sulphuric acid (50cc. to 10grms. of the slag) is slowly stirred in. The mixture is subsequently heated on a sand-bath until it has the consistency of a thin paste, the phosphoric acid being finally determined by the molybdate method. It is not necessary to oxidise the ferrous compounds before addition of the molybdate solution. The results obtained by the author with this process are slightly higher (about 0·05 per cent.) than those obtained by digestion with hydrochloric acid, thus proving that more complete solution of the phosphates is effected by the concentrated sulphuric acid.—E. E. B.

The Estimation of Ammonia in Soils. W. Knop. Zeits. Anal. Chem. **26**, 1.

THE method proposed by the author in conjunction with Wolf, in 1859, for the estimation of ammonia in soils, by the decomposition of the ammonia by a strongly alkaline Javelle solution (sodium hypochlorite solution) and sodium hypobromite, and measurement of the nitrogen liberated, was liable to yield fallacious results on account of the contraction which many soils suffer when shaken up with strongly alkaline liquids. This contraction appears to be due to a reaction between the water, some of the mineral constituents of the soil (especially ferruginous clays), and the alkali, new compounds being formed, and this formation being attended by condensation. Of course, it is well known that when peaty soils and soils rich in humus are shaken up in a closed flask with an alkaline solution, a contraction in bulk of the air above the liquid takes place, but this is due to the absorption of oxygen, and the reaction is similar to the absorption of oxygen by an alkaline solution of pyrogallic acid. The contraction of the soil which has hitherto led to the vitiation of the ammonia estimations must therefore not be confounded with the absorption of oxygen, and it is to be remarked that contraction also takes place when the flask is filled with hydrogen in place of air. The author now finds it possible to avoid this contraction by employing a solution of sodium hypobromite saturated with borax, care being taken that the amount of free sodium hydrate is not more than 0·5grm per 200cc. borax solution; but although with this proportion of free alkali, few soils will show any contraction, it is advisable to determine with every sample of soil the proportion of alkali with which contraction begins to occur and also the amount of such contraction, if any. As it is not easy to prepare a solution of hypobromite with the desired proportion of caustic soda, a solution prepared according to the following plan is employed and this whilst sufficiently alkaline to decompose ammonia is not liable to cause any contraction. To an excess of calcium hydrate are added 200cc. of water and 15cc. of bromine, the mixture is allowed to stand several days to become saturated with lime, then filtered and mixed with a saturated solution of borax before use. In the actual performance of the test it is not advisable to employ more than 100grms. of the sample of soil, and the flask should be provided with a thermometer inserted through a tubulus, so that precautions may be taken against changes of temperature. Prolonged shaking is not necessary, as the decomposition of the ammonia appears to proceed readily and easily.—W. D. B.

On the Determination of Nitrogen in Manures containing Saltpetre. A. Stutzer and O. Reitmer. Rep. Anal. Chem. **7**, 4—6.

THE well-known method of estimating nitrogen in manures by ignition with soda-lime, has been to a large extent abandoned in favour of the process proposed by Kjeldahl. This method, which may be named the "sulphate method" has been considerably modified since its introduction; concentrated sulphuric acid and metallic mercury alone being now employed, instead of the fuming sulphuric acid, phosphoric acid and permanganate originally used. The sulphate method, like the soda lime process, is not applicable to nitro compounds, and in order to remedy this defect, Jodlbaur has suggested the employment of phenolsulphonic acid, instead of sulphuric acid. The nitro phenol can be converted by means of zinc-dust into amido-phenol, the nitrogen in which can be estimated by the sulphate method. The authors find that the method (this Journal, 1886, 510) does not give good results when the manure contains much saltpetre, or when the substance examined is sodium or potassium nitrate; but, by a slight modification, satisfactory results can be obtained even with the nitrates themselves. It is of great importance that the phenolsulphonic acid should *not* be allowed to act upon compact masses of the substance: for when this occurs, the nitration does not proceed quantitatively. 1grm. of the manure should be taken, 25cc. of water added and the whole evaporated down to dryness. If the solution to be analysed is a nitrate, it is best to take 10grms. and dissolve in 500cc. of water; 25cc. of the solution are evaporated down in a dish of about 350cc. capacity, the evaporation being best conducted in an air bath at 100—110. The substance is now in a finely-divided state, and, after cooling, 50cc. of sulphuric acid containing 20grms. of phenol per litre, are poured in. After standing for a few minutes, 2—3grms. of dry pure zinc-dust and one or two drops of mercury are added and the mixture boiled. The conversion into ammonium sulphate is complete in 1½ hours when the ammonia is distilled off.—D. E. J.

Detection and Estimation of Small Quantities of Chromium. E. Donath and R. Jeller. Rep. Anal. Chem. **7**, 33—34.

In order to separate traces of chromium from large quantities of iron, alumina and manganese, the solution containing these substances together with the bases of the alkaline earths, is poured into a hot solution of sodium carbonate, to which some permanganate has been added. The liquid is boiled for a few minutes, a few drops of alcohol are added, to reduce the excess of permanganate to manganese peroxide and the whole is filtered; the metals and alkaline earths are thus precipitated, while the chromium oxide is converted by the hot alkaline permanganate into chromate and thus passes into the filtrate. When a considerable quantity is present, it can be recognised by the yellow colour of the filtrate; otherwise it should be evaporated down, acidified, and tested with a small piece of starch moistened with a freshly-prepared solution of KI, the chromic acid, even in very dilute solutions, decomposing the hydriodic acid. For quantitative work, the filtrate containing the chromate is acidified with HCl and a little alcohol added; the chromium oxide is precipitated in the usual way by ammonium sulphide.—D. E. J.

Valuation of Rich Copper Ores. E. Donath and R. Jeller. Rep. Anal. Chem. **7**, 34—35.

In estimating copper volumetrically by potassium cyanide, a previous precipitation of the copper by zinc is necessary in order to separate it from iron contained in the ore (Steinbeck's process). The solution of the copper-ore and the separation of the copper from iron, etc., can be expedited as follows:—The finely-powdered ore is mixed with twice its volume of zinc-dust and heated in a porcelain crucible for ten minutes; the sulphur of the metallic sulphides combines with the zinc, forming zinc sulphide. On treatment with dilute acid (1 of H_2SO_4 to 3—4 of water), the iron, zinc sulphide and excess of zinc are dissolved out, leaving the copper and insoluble matter behind. After washing by decantation with hot water, the copper can be dissolved by dilute nitric acid and the titration carried out in the usual manner.—D. E. J.

Separation of Alumina from Iron by Chancel's Method. E. Donath and R. Jeller. Rep. Anal. Chem. **7**, 35—36.

This method consists in boiling the neutral solution with sodium thiosulphate, the alumina being thus precipitated together with sulphur. The writers have tested the method, using solutions of alum of known strength, and they find that the precipitation of the alumina is not complete (in five examples given, the mean deficiency was 4). But on boiling down the filtrate and wash-waters, a further precipitate is obtained, and the sum of the two is found to be in excess of the quantity of alumina contained in the original solution; the explanation being that the alumina obstinately retains a portion of the co-precipitated sulphur. In this state it takes a yellow colour on heating (just like ZnO), becoming white again when cold; it can be freed from sulphur by strong ignition and does not then become yellow when hot.

The method gives satisfactory results under the following conditions:—The solution containing the oxides should be very dilute and must be boiled down to half its volume; the filtrate and wash-waters being again boiled down and the second precipitate collected. The alumina must be ignited over a blow-pipe until it no longer shows a yellow colour when hot.—D. E. J.

ABSTRACT FROM A LECTURE AT THE ROYAL INSTITUTION "ON THE WORK OF THE IMPERIAL INSTITUTE," ON 22ND APRIL, 1887.

BY SIR F. A. ABEL, C.B., D.C.L., F.R.S.

After generally indicating the scope and design of the Imperial Institute, Sir Frederick proceeded:—

"In 1852 Sir Lyon Playfair, in one of a course of most interesting lectures on some of the results of the preceding year's great Exhibition, was impelled by the teaching of that great world's display to point out that 'the raw material, formerly our capital advantage, was gradually being equalised in price and made available to all by the improvements in locomotion,' and 'that industry must in future be supported not by a competition of local advantages, but by a competition of intellect.' If this was already felt to be the state of the case six-and-thirty years ago, how much more must we be convinced of the full truth of this at the present day by the conditions under which the British merchant and manufacturer have to compete with their rivals on the Continent and in the United States.

"It is still within the recollection of many that almost the whole world was in very great measure dependent upon Great Britain for its supplies of ordinary cast-iron. Even as lately as 1871 the United States of America received from Great Britain nearly one-fifth of its total produce of pig-iron; but from 1875 all importation of British iron ceased for over three years, and it was only in consequence of requirements in the States exceeding the capabilities of production that some small demands arose in 1879, which were for some time maintained.

"But while, in 1879, the pig-iron produced in the United States amounted to little over 3,000,000 tons, to 1882 the make had increased by 70 per cent.—viz., in over 5,100,000 tons. Since that time the actual make has not increased (in 1885 it amounted to 4,529,869 tons of 2000lb.), but the *capacity of production*, which vitally interests the iron trade of this country, has risen enormously, the present capacity of all the American pig-iron works being estimated at over 8,900,000 tons, or nearly 300 per cent. greater than it was in 1879. So much regarding the United States. Looking nearer home, we find that the iron of France, Belgium, and Germany not only competes with ours in the open market, but that Belgian and German iron is actually imported into this country to a moderate extent.

"As an instructive illustration of the advance and influence of the improvements which have been made in intercommunication upon the value of our natural products and their importance even in our own industries, I

may, on the authority of Sir Lowthian Bell, state the astounding fact that, in the opinion of competent authorities, the ore (hæmatite) especially suitable for steel manufacture by the Bessemer process can be brought over sea a distance of 1000 miles, landed close to mines furnishing the cheapest made pig-iron of Great Britain, and converted into *steel* rails at a lower cost than the native ironstone of Cleveland can furnish similar rails in *iron*.

"From time to time the ground which we have lost through the development of the resources of other countries has been more than retrieved temporarily by improvements effected through the more thorough comprehension and consequent better application of the scientific principles underlying processes of manufacture. Thus the quantity of fuel consumed in producing wrought-iron rails has been gradually reduced by improvements in the construction and working of furnaces, until less than one-half the amount is now required per ton of such rails than was employed fifty years ago; but, remarkable as it may seem, the ultimate effect of an advance of this importance is actually to improve the position, in relation to this manufacture, of other nations less favourably circumstanced than Great Britain in the matter of coal, for, instead of having to multiply any difference in our favour in the cost of fuel required to produce a ton of rails by twelve, that difference has now only to be multiplied by three in order to arrive at the extent of our advantage.

"The history of the development of steel manufacture during the last twenty-five years affords a most instructive illustration of the fluctuations which may ensue in the value of our natural resources, and the consequent condition of one or other of our important industries, arising out of continued advances made in the application of science to the perfection or transformation of manufacturing processes, and of the stimulating effects of such fluctuations upon the exertions of those who are able to bring scientific knowledge to bear upon the solution of problems in industrial operations which entirely baffle the ordinary manufacturer. Within that period the inventions of Bessemer and of Siemens have led to the replacement of iron by steel in some of its most extensive applications. The Bessemer converter, by which pig-iron is rapidly transformed into steel by the injection of air into the molten metal, has, so far as this country is concerned, to a very great extent, superseded the puddling furnace, in which pig-iron is transformed by long-continued laborious treatment into steel or malleable iron. This important change in our national industry was, ere long, productive of a serious crisis therein, and for the reason that the pig-iron produced from a large proportion of those ores which, from their abundance and the cheapness of their treatment, have been largely instrumental in placing Great Britain in her high position as an iron-producing nation, could not be applied to the production of marketable steel by means of the Bessemer converter. In the purification of this pig-iron during its conversion in the puddling furnace into a suitable material for the production of rails, the elementary constituent phosphorus, which it had carried with it from the ore as a contaminating ingredient very detrimental to its strength, was eliminated, and by sufficient treatment a malleable iron of good quality was obtained; but in the production of steel from the same material in the Bessemer converter, the phosphorus is almost entirely retained in the metal, rendering it unsuitable for manufacture into rails or plates. Hence the application of this rapid steel-making process had to be chiefly restricted to particular kinds of ores, the supplies of which are limited to a few districts in this country. These had to be largely supplemented by importations from other countries; nevertheless the cheapness of production and superiority in point of strength, durability and lightness of the steel rails thus sent into the market from the Bessemer converter combined to maintain a supremacy of them over iron rails, etc., manufactured by the old puddling processes from the staple ores of the country.

"The advantages presented by steel over the wrought-iron of the puddling furnace for constructive purposes speedily became evident; combining as it does nearly double the strength with a more than proportionate superiority in elasticity and ductility, its value for shipbuilding purposes did not long fail to be realised. It was soon found more profitable to build a steel steamer, paying a price of nearly £9 per ton for the material, than to construct one of iron which cost only £6 5s. per ton. The effect of the rapid displacement of malleable iron by steel produced from ores of a particular class has been, that at least 85 to 90 per cent. of the iron ores of Great Britain could no longer be applied to the production of material for rails and for constructive purposes, being unavailable for steel-making by any method which could compete with the Bessemer and Siemens processes. Great has been the apprehension among the owners of those ores, that the demand for iron which they can furnish could not revive, but the scientific metallurgist has successfully grappled, from more than one direction, with the great problem of restoring their commercial importance.

"Modifications of the mode of working the rival of the Bessemer process—viz., the open-hearth (Siemens-Martin) process—have given successful results in the production of serviceable rails containing higher proportions of phosphorus than had before been admissible, and a simple alteration of the method of carrying out the Bessemer process has, within the last few years, led to really triumphant results, with the employment of those ores which before could only be dealt with by the searching operation of the old puddling furnace. By utilising the basic character of lime during the treatment of the melted pig-iron, yielded by phosphoric ores, with ores in the Bessemer converter, the phosphorus is fixed at the moment of its elimination by oxidation from the metal, and the objectionable impurity is held bound in the slag, while a steel is obtained rivalling in freedom from phosphorus the product furnished by the pure varieties of English and foreign ore which alone could previously be successfully dealt with by the Bessemer process. This modified treatment of iron for the production of steel, called the *basic treatment*, was soon applied also to the open-hearth (the Siemens and Siemens-Martin) processes of steel-making; thus a new era was established in steel manufacture by the quick processes, there being now but very few restrictions to their application to iron produced from all varieties of ores. Indeed the treatment is actually being applied profitably to the recovery of iron from the rich slag forming the refuse-product of the puddling furnace in the production of malleable iron, which, containing as it did the phosphorus eliminated from the pig-iron by the laborious purifying treatment, had been condemned to limited usefulness as a material for road-making, while now it ranks in market value with some ores of iron. Yet another most interesting and valuable result has been achieved by this simple application of scientific knowledge. The slag or refuse-product of the basic treatment of iron contains, in the form of phosphates of lime and magnesia, the whole of the phosphorus which it is the main function of that treatment to separate from the metal; it was soon found that the phosphoric acid which had been produced by the elimination of the pernicious element in the conversion of bad iron into good steel, existed in this refuse-slag in a condition as readily susceptible of assimilation by plants as it is in the valuable artificial manure known as superphosphate; this refuse-slag, simply ground up, constitutes therefore a manure which is already of recognised value and commands a ready sale at very profitable prices.

"The organisation of this latest advance in the development of steel manufacture dates back only nine years, and already the year's product of the basic process amounts to over 1,300,000 tons of steel. But although it is to Englishmen that the owner of iron property and the steel-maker are again indebted for these important results, and to English manufacturers that the first practical demonstration of the success of this process is due, its application has been far more rapidly elaborated upon the Continent than here; in Germany the importance of the subject was at once realised, and it is there that considerably the largest proportion of steel is produced by the basic treatment; it is in Germany also that the value of slag for agricultural purposes has been developed; the first steps in its utilisation here being but just now taken, in Staffordshire.

"I have already referred to the remarkable strides which have been made in the extension of iron manufacture in the United States: the development there of steel production has been no less marvellous. In 1879, 928,000 tons of Bessemer steel were produced; in 1885 the make amounted to 1,701,000 tons, while the productive capacity in that year was estimated at 4,102,000 tons. With other extensive steel-producing works in course of completion, provision is being made for increasing the power of production by another million tons. Looking to the fact that at the present time the railway mileage in the United States exceeds that of the whole of Europe, there being 1,300,000 miles of railway in operation, while at the beginning of 1865 there were only 34,000 miles, the causes of this enormous development of the iron and steel manufacture are evident; the resources of the country in ore and fuel are gigantic, and the systematic technical training of the people has made its influence felt upon the development of this as of every other branch of industry which our friendly rivals pursue. But it is not only in the United States that the development in the production of iron and steel has greatly increased of late years; thus, in Germany the increase in the production of pig-iron alone, during the last twenty-one years, has been 237 per cent., in Austro-Hungary 152 per cent., while the increase in France and Belgium is 64 per cent., and therefore not greatly inferior to our own (75 per cent.).

"Although, however, the increase in actual production of iron and steel in this country has not kept pace with that of some other countries, it is satisfactory to know that our *productive power* has very greatly increased in late years, and there is probably no one branch of our industries in which we have maintained our position so satisfactorily in regard to quality of product as that of iron and steel manufacture, even although, every now and then, we have indications that in the struggle with other nations for superiority of product and for pre-eminence in continuity of progress, we have to look to our laurels. While the country owes a deep debt of gratitude to such men as Neilson, Mushet, Bessemer, Siemens, Thomas and Gilchrist, who by their brilliant discoveries and inventions have maintained Great Britain's position as leader in the origination of successive eras of advance in iron and steel manufacture, there is no question that the trade generally has in recent years derived the greatest assistance and benefit from the organisation of the Society which, under the name of the Iron and Steel Institute, has brought the members of the trade to recognise that they themselves, and the country, reap incalculable benefit from their free interchange of knowledge and the results of experience, their candid discussion of successes, failures, and diversities of views and practice—the combination of friendly rivalry with hearty co-operation in the advancement of science and practice of their important calling.

"While we have succeeded in maintaining a foremost position in the iron and steel manufacture, there are some other important branches of industry, for a time essentially our own, the present condition of which, in this country, we cannot contemplate with equal satisfaction. Several instructive illustrations might be quoted, but I will content myself with a brief examination of one of the most interesting.

"A glance at the history of the utilisation of some products of the distillation of coal will present to us an industry created and first elaborated in England, which has, on the one hand, by its development effected momentous changes in other industries and in important branches of commerce, while on the other hand it has been in great measure wrested from us in consequence of the systematic collaboration of scientific and practical workers on the Continent."

Referring to the recent advances in chemical manufactures, and tracing step by step the discoveries in chemical science which led up to or greatly influenced these advances, Sir Frederick Abel emphasised as a specially interesting example the replacement of madder by coal tar alizarin. He then showed how that the manufacture of new colours and other coal-tar products led to the demand for new reagents and materials to serve as ingredients, and thus, substances formerly only laboratory curiosities, like phosgene, had come to be commercial products. The present magnitude of the coal tar colour industry was then referred to, both as regards quantity and value.

"These figures show that the value of the make of colours in England was less than one-fourth that of Germany, and that even Switzerland, which, in competing with other countries industrially, is at great natural disadvantages, was not far behind us, ranking equal to France as producers. The superior position of Germany in reference to this industry may be in a measure ascribable to some defects in the operation of our Patent Laws and to questions of wages and conditions of labour; but the chief cause is to be found in the thorough realisation by the German manufacturer of his dependence for success and continual progress upon the active prosecution of scientific research, in the high training received by the chemists attached to the manufactories, and in the intimate association, in every direction, of systematic scientific investigation with technical work.

"The young chemists which the German manufacturer attracts to his works rank much higher than ours in the general scientific training which is essential to the successful cultivation of the habit of theoretical and experimental research, and in the consequent appreciation of, and power of pursuing, original investigations of a high order. Moreover, the research laboratory constitutes an integral part of the German factory, and the results of the work carried on by and under the eminent professors and teachers at the universities and technical colleges are closely followed and studied in their possible bearings upon the further development of the industry.

"The importance attached to high and well-organised technical education in Germany is demonstrated not only by the munificent way in which the scientific branches of the universities and the technical colleges are established and maintained, but also by the continuity which exists between the different grades of education; a continuity, the lack of which in England was recently indicated by Professor Huxley with great force. Nearly every large town in Germany has its 'Real Schule,' where the children of the public elementary schools have the opportunity, either by means of exhibitions or by payment of small fees, of receiving a higher education, qualifying them in due course to enter commercial or industrial life, or to pass to the universities or to the polytechnic or technical high schools, which, at great cost to the nation, have been developed to a remarkable extent in recent years, and have unquestionably exercised a most beneficial influence upon the trade and commerce of the country. A most important feature in the development of these schools is the subdivision of the work of instruction among a large number of professors, each one an acknowledged authority in the particular branch of science with which he deals. Thus, at the Carlsruhe Polytechnic School—one of the very earliest of its kind, which was greatly enlarged in 1863—the number of professors is 41; and at Stuttgart the teaching staff of the polytechnic school amounts to 65 persons, of whom 21 are professors.

"The important part taken by the German universities in the training of young men for technical pursuits has often been dwelt upon as constituting a striking feature of contrast to our university systems. The twenty-four universities in the German Empire, each with its extensive and well-equipped science departments and ample professional staff, contribute most importantly to the industrial training of the nation in co-operating with the purely technical schools. The facts specified in the Report of the Technical Education Commission that, in the session 1883—4, there were 400 students working in the chemical laboratories at Berlin, and that, during the same session, 50 students were engaged in original research at Munich (where the traditions of the great school of Liebig are worthily maintained), illustrate the national appreciation of the opportunities presented for scientific training; and the expenditure of £30,000 upon the physical laboratory, and £35,000 upon the chemical department, of the New University of Strasbourg, serves to illustrate the unsparing hand with which the resources of the country are devoted to the provision of those educational facilities which are the very life-spring of the industrial progress whence those resources are derived."

THE BRITISH COLONIES.

(ILLUSTRATIONS OF THEIR DEVELOPMENT DURING THE QUEEN'S REIGN.)

Imports and Exports.

		IMPORTS £	EXPORTS. £
American Dependencies	1837	5,200,000	5,000,000
	1885	25,700,000	21,500,000
Australasia	1837	1,500,000	1,300,000
	1885	63,500,000	52,000,000
Africa	1837	2,000,000	1,500,000
	1885	10,000,000	12,000,000

All the Imports and Exports taken together were ELEVEN TIMES larger in 1885 than they were in 1837.

British Shipping Trade with Colonies	1837	3,700,000 tons.
	1885	56,600,000 ,,
British Export to Colonies	1837	£11,300,000
	1885	£51,500,000

Population.

Of all the Colonies existing in 1837	1837	4,204,700
	1881	12,753,277[*]
Of all the Colonies in 1881		15,763,072[*]

Rate of Increase from 1837 to 1881.

In European Colonies	SLIGHT.
In Ceylon	TWICE as large as it was.
In the Great Asiatic Colonies	About the SAME.
In the Cape of Good Hope	EIGHT TIMES as large as it was.
In Canada	THREE TIMES as large as it was.
In the West Indies	NOT quite TWICE as large as it was.
In Australia	Nearly TWELVE times as large as it was.

Trade Report.

(From the Board of Trade Journal.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

RUSSIA.

Recent Customs Decisions.

(*Note.*—Poud = 36lb. avoirdupois. Gold rouble = 3s. 2d.)

White Vaseline.—Section 140, duty 2 roubles per poud, with an addition of 20 per cent. on each rouble of duty leviable.

Aniline Dyes in small paper parcels. Section 120, duty (including dye and wrapper) 15 roubles per poud.

FRANCE.

Increase in Sugar Duties.

With reference to the notification that appeared respecting a proposed increase in the French sugar duties, a report, dated the 27th May last, has been received from Mr. J. A. Crowe, Her Majesty's Commercial Attaché for Europe, stating that the Chamber of Deputies and the Senate have passed the Bill establishing provisionally and until the 31st December next, a surtax on sugar of every origin to the extent of 20 per cent.—*i.e.*, at the rate of 10 francs per 100kilos. Molasses, other than for distillation, having a saccharine richness of 50 per cent. or less, are to pay a duty of 18 francs per 100kilos.; but if more than 50 per cent. they are to pay a duty of 38 francs 40 cents per 100kilos. Chocolate is to pay a duty of 98 francs 40 cents per 100kilos.

SWITZERLAND.

Classification of Articles in Customs Tariff.

(*Note.*—Quintal = 220·4lb. avoirdupois.)

The following decisions affecting the classification of articles in the Swiss Customs Tariff have been given by the Swiss Customs Authorities during the month of March last:—

The word "purified" to be added to Category 9*a*, after "lanoline."

Chlorate of baryta. Category 17, duty 1 franc per quintal.

Amber, raw, liquid. Category 18*a*, duty 1 franc 50 centimes per quintal.

Plates of glass, prepared for use in photography. Negative photographs on glass are no longer included in Category 95.

Lanoline, raw, not purified. Category 260, duty 50 centimes per quintal.

ITALY.

Classification of Articles in Customs Tariff.

(*Note.*—Quintal = 220·4lb. avoirdupois. Kilogramme = 2·204lb. avoirdupois. Hectolitre = 22 imperial gallons. Lira = 9$\frac{6}{10}$d.)

The following decisions affecting the classification of articles in the Italian Customs Tariff have recently been given by the Italian Customs authorities:—

Pure spirit, of 95 degrees, to which has been added a small quantity of essence of aniseed. Category 1, No. 5*a*, duty 12 lire per hectolitre.

Extract of sumach, for dyeing. Category 3, No. 29*c*, duty free.

Chloride of cinconina (alkaloid combined with chloric acid). Category 3, No. 32*b*, duty 5 lire per kilo.

Oxide of iron hydrate, with an admixture of carbonate of soda, intended for purifying illuminating gases. Category 3, No. 33, duty 2 lire per quintal.

"Acetanilid" (product derived from aniline and acetic acid, used for medicinal purposes). Category 3, No. 55, duty 10 lire per quintal.

"Resorcina" (a medicine). Category 3, No. 55, duty 10 lire per quintal.

Malt extract (medicinal). Category 3, No. 56, duty 120 lire per quintal.

Wine, containing quinine mixed with sugar. Category 3, No. 56, duty 120 lire per quintal.

Waggon grease. Category 3 No. 58*a*, duty 6 lire per quintal.

Red arsenic, pulverised. Category 4, No. 66, duty 12 lire per quintal.

Varnish, composed of resin dissolved in alcohol, and coloured with oxide of iron. Category 4, No. 67*a*, duty 30 lire per quintal.

Artificial black, in very fine powder, used instead of lamp-black. Category 4, No. 70*c*, duty 5 lire per quintal.

Foundry slag and iron scoriæ, used as manure. Category 15, No. 296, duty free.

SPAIN.

Classification of Articles in Customs Tariff.

(*Note.*—Kilogramme = 2·204lb. avoirdupois. Peseta = 9$\frac{6}{10}$d.)

The following decisions affecting the classification of articles in the Spanish Customs Tariff have recently been given by the Spanish Customs authorities:—

Carbon filters, with receiver of fine varnished earthenware. Category 16, duty 26ps. 58cs. per 100kilos.

Oxide of cobalt, pulverised, mixed with flint, to give a blue colour to majolica and porcelain. Category 70, duty 4ps. 80cs. per 100kilos.

Calcotite, a product used for making walls waterproof. Category 92, duty 10 cents. per kilog.

UNITED STATES.

Customs Decisions.

The following decisions affecting the classification of articles in the Customs Tariff, and the application of the Customs Laws of the United States were given by the United States Government during the month of April last:—

Paper filters which are in the form of discs are dutiable at the rate of 15 per cent. *ad valorem*, as manufactures of paper, but filtering-paper in sheets, which has not been manufactured into filters, and which is simply paper adapted by its character for filtering purposes, is dutiable at the rate of 25 per cent. *ad valorem*, under the provision in Section 392, for "all other paper not specially enumerated or provided for."

Platinum sheets and wire which have undergone a further process of manufacture than that which brought the crude material into commercial platinum are dutiable at the rate of 45 per cent. *ad valorem*, under the provision in Section 216, for "manufactures, articles, or wares, not specially enumerated or provided for in this Act, composed wholly or in part of . . . platinum."

---

[*] These numbers must have considerably increased since 1881.

Photographic paper which has been subjected to the process of sensitising or albumenising, is held, under the recent decision of the court, and by the advice of the United States Attorney-General, to be dutiable at the rate of 15 per cent. *ad valorem*, under the provisions of Section 388, for "manufactures of paper . . . not specially enumerated or provided for."

MAURITIUS.

New Customs Tariff.

With reference to the notification respecting the alteration in the rates of Customs duties now levied in Mauritius, the following detailed statement has been prepared, showing the Customs duties now levied on imports into that colony compared with the rates previously in force.

Goods.	New Rates of Duty.	Old Rates of Duty.
	Rupees Cs.	Rupees Cs.
Manure of all sorts; and the following substances when imported for the purpose of being used in the preparation of manures or other colonial produce, or as disinfectants, viz.:—Ammoniacal liquor, bones, bone dust, bone oil, and dissolved bones, carbolic acid, chloride of lime, chloride of manganese, chloride of soda, solution of soda, chloride of zinc, coal and wood soot, dried muscular flesh and dried blood, ether, fish and other substances damaged and condemned by the Customs sanitary officers as fit for manure only, lime, carbonate of lime, sulphate of lime or gypsum, phosphate and superphosphate of lime, nitrates, silicilates, and carbonates of potash and soda, perchloride of iron, permanganate of potash, phosphate of soda, sulphate of iron, sulphate and muriate of ammonia and other ammoniacal salts, sulphate of potash, sulphate of zinc, sulphuric acid, urate and sulphurated urine	1000kilos. 0·25	Free.

CUSTOMS TARIFF OF CHILI.

(Peso = 4s. 2d.)

NOTE.—The surcharge of 40 per cent. levied on all the duties payable in Chili was raised on the 1st April last to 45 per cent., and will remain at that rate until the 31st December next. During the year 1888 it will be at the rate of 47 per cent., and at 50 per cent. commencing from the 1st January, 1889.

Articles, Etc.	Valuation.	Duty.
	Ps. Cs.	
Drugs, Patent Medicines, and Chemical Products—		
Sulphate of Copper	Kilog. 0·15	15% ad val.
Of every other kind	—	25% ad val.

TRADE BETWEEN SPAIN AND THE UNITED KINGDOM.

Soap ....Cwt.	940	432
Value	£768	£392
Total Value	£273,145	£246,897

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

THE DEPRESSION IN THE BELGIAN COAL TRADE.

Lord Vivian, Her Majesty's Minister at Brussels, in a dispatch dated the 14th April last, on the subject of the steps taken by the Belgian Government respecting the depression in the Belgian coal trade, says:—

"In view of the depressed condition of the coal trade in Belgium, the Government are instituting an inquiry into the question, and have appointed two committees to examine it both from a commercial and industrial point of view, with the object of developing the trade.

"The commercial committee has nearly concluded its labours, but the inquiry into the industrial side of the question will not be completed for some time. I am promised a copy of the report when it is ready.

"Meanwhile, I am informed that it has been exclusively shown that the present railway rates for the transport of Belgian coal for foreign markets are already so low as to leave no margin of profit which would admit of their further reduction, and that it is therefore doubtful whether it would be possible to export the Charleroi smokeless coal to England at a profit by railway; the question of the cost of transporting it by canal is now under consideration.

"The industrial committee is charged to ascertain and report what improvements and economies can be made (1) in the plant and machinery used in the mines for the extraction of the coal, and (2) in the machinery for loading and unloading it at the stations and ports."

DEPÔT OF RUSSIAN PETROLEUM AT GOTHENBURG.

Mr. John Duff, Her Majesty's Consul at Gothenburg, in a report dated 11th of May last, states that Messrs. Nobel, of Baku, on the Caspian Sea, petroleum manufacturers, have made arrangements for a depôt of their oil at Karingberget, on the south shore of the mouth of the river Gota, about six miles from Gothenburg, where a reservoir, to hold two thousand tons of petroleum, will be built.

MISCELLANEOUS TRADE NOTICES.

CHEESE ADULTERATION IN THE UNITED STATES.

See *Board of Trade Journal* for June.

TRADE OF BOLIVIA.

In an article contributed to *L'Economiste Français* of 30th April last, on the economic resources of Bolivia, M. A. F. de Fontpertuis draws attention to the fact that the trade of that country is almost entirely in the hands of foreign houses, mainly belonging to Germany, France and Spain. There are no English or American merchants in Bolivia; but the Germans, he says, arrive in great numbers. Speaking English and Spanish with fluency, they soon find themselves at the head of a thriving trade. They undertake to buy their goods entirely in Europe, and mainly in Germany, and they recoup themselves by purchasing the products of the country and sending them to Europe. The main elements of the commercial wealth of Bolivia are saltpetre and guano, and the natural stores of these articles were, so M. de Fontpertuis declares, the real cause of the late fratricidal war with Chili.

RUSSIAN SUGAR PRODUCTION.

The *Journal de St. Petersburg* for the 6th May last collects the opinions of the leading provincial Russian newspapers on the question of regulating the production of sugar by limiting its quantity, and insisting on the exportation of a considerable percentage. This question has been raised by the meeting of the principal sugar refiners of Russia, to the number of 114, at Kiev, in the first week of the month of May. The general opinion of these newspapers, according to the *Journal*, is that it will be advisable for the refiners to carry out their proposition of pledging themselves to export, at any price, twenty-five per cent. of their actual production, and that for three full years from the close of 1887. This, it is believed, is the only course by which the markets of Russia can be relieved, although it is not to be concealed that the dearer rate at which the remaining three-quarters of the sugar will have to be sold in the markets of the Empire will lead to many complaints.

COMMERCIAL INSTITUTE OF PARIS.

The *Moniteur Officiel du Commerce* for the 28th April last, states that on the 10th of March last, at an extraordinary meeting of the shareholders, it was unanimously determined to greatly increase the importance of the Commercial Institute of Paris; to remove it to a more important building; and to expend upon it enough money to give it a far greater place than it has ever before held in the development of technical training and the general commercial prosperity of France.

EXTRACT FROM REPORT ON THE NEW CUSTOMS LAW AND TARIFF OF MEXICO.

"A large reduction has been made in the duties on drugs and medicines, but the duties in many cases are still extravagantly high—*e.g.*, alkaloids and their salts not specified (131) 15 dollars per kilo. The effect of these high duties on medicines is two-fold.

(1) The poor are often unable to obtain proper medicines, and have to content themselves with cheaper substitutes;

(2) Drugs and medicines are often smuggled, especially those that are taxed the most heavily, and the exchequer obtains less revenue from the high duties than it would from moderate duties.

"On the whole, the new tariff is a considerable improvement on the old one; but it remains highly protective."

ANILINE DYES.

A noticeable feature, says the *Journal of the Society of Arts*, in the Indian trade returns is the large increase in the employment of aniline dyes in India, in the place of the indigenous colours formerly employed for their woollen yarns, silk, and cotton. The value of the imports now averages £100,000 a year. The imports of aniline dyes were of the value of £77,159 in 1883, £110,321 in 1884, £101,395 in 1885, and £61,619 in the first eight months of 1886.

DRUGS AND CHEMICALS IN DAMASCUS.

According to the *Petit Moniteur*, French pharmaceutic and photographic chemicals have taken the first rank in the Damascus trade, the Paris houses exporting goods against which nothing can be said as regards quality; but their high prices check trade, and consequently leave an opening for German competition, which the Teutons avail themselves of, especially in the colour trade and heavy products. The supply of sulphate of quinine found in the market is almost entirely of Italian origin. The correspondent does not mention English goods, which have probably escaped his notice; he estimates the value of imports thus—Chemicals employed in the city, 50,000f.; drugs, 30,000f.; colouring matters, 10,000f.; hospital supplies, 19,000f.

GENERAL VIEW OF THE WORLD'S TRADE.

See *Board of Trade Journal* for June.

STATISTICAL TABLES.

PERIODICAL RETURNS OF IMPORTS AND EXPORTS.

Imports and Exports into and from the under-mentioned Countries in the latest Month for which Returns have been received, with Aggregates for the Period of the Year, including such latest Month.

(*Note.*—Rouble = 2s. 0d.; Franc = $9\frac{6}{10}$d.; Milreis = 4s. 6d.; Lire = $9\frac{6}{10}$d.; Dollar = 4s. 2d.; Piastre = $2\frac{1}{2}$d.)

The above figures are subject to revision in the Annual Returns.

NOTE.—The figures are those of the "special" imports and exports, except in the case of the United States and British India, where the figures are "general." "Special" means, in the case of imports, imports for home consumption, in the case of exports, exports of domestic produce and manufacture only.

* The aggregate figures are for the financial year commencing 1st April.

TRADE STATISTICS FOR MAY.

The Board of Trade Returns for May show the following figures :—

Exports.

	May, 1886.		May, 1887.
British and Irish Produce	£16,301,022	....	£16,497,836
Foreign and Colonial Produce (partly estimated)	4,592,142	....	4,700,128

Imports.

	May, 1886.		May, 1887.
Total value....................	£29,023,303	....	£27,921,321

Below are the details affecting drugs and chemicals :—

Exports.

		May, 1885.	May, 1886.	May, 1887.
British and Irish produce :—				
Alkali	cwt.	629,771	644,144	560,831
,, ...	value £	186,382	182,420	157,981
Bleaching materials	cwt.	149,089	112,218	125,187
,, ,,	value £	48,246	43,116	47,147
Chemical manure ..	value £	90,789	94,286	90,579
Drugs and medicinal preparations (unenumerated)	value £	64,126	65,121	69,607
Other chemicals and medicinal preparations	value £	161,266	171,847	177,352
Oil (seed)............	tons	5,393	7,228	6,613
,, ...	value £	126,175	148,955	134,922
Soap	cwt.	31,992	27,738	36,766
,, ...	value £	37,238	30,513	36,767
Painters' colours and materials (unenumerated)	value £	105,900	109,025	119,391
Foreign and Colonial merchandise :—				
Bark, Cinchona	cwt.	10,178	10,917	11,086
,, ,, ...	value £	49,566	48,837	47,749
Chemicals (unenumerated)	,,	21,955	16,010	25,288
Cochineal	cwt.	804	649	353
,, ...	value £	5,280	4,525	2,418
Cutch and gambier	tons	732	530	835
,, ,,	value £	17,721	13,029	21,378
Gum Arabic	cwt.	4,157	3,613	2,963
,, ...	value £	15,072	12,574	10,506
Indigo	cwt.	3,982	1,722	3,488
,, ...	value £	82,650	31,857	73,043
Lac, various kinds..	cwt.	7,617	6,045	4,595
,, ,, ,, ..	value £	24,431	16,078	13,411
Lard	cwt.	3,013	13,957	1,583
,, ...	value £	5,606	28,319	2,850
Oils, cocoa-nut......	cwt.	12,412	6,593	10,643
,, ,, ...	value £	18,631	8,822	13,906
,, olive	tuns	254	307	393
,, ,, ...	value £	11,925	13,185	16,979
,, palm	cwt.	26,087	32,708	32,548
,, ,, ...	value £	37,278	32,380	31,719
,, petroleum	gals.	35,566	35,744	70,026
,, ,, ...	value £	1,867	1,550	2,552
Quicksilver	lb.	240,396	416,731	301,062
,, ...	value £	17,792	32,281	27,196
Nitre (nitrate of potash)	cwt.	1,377	739	5,721
Nitre (nitrate of potash)	value £	1,380	591	5,397
Tallow and stearine	cwt.	17,583	15,113	56,479
,, ,, ,, ..	value £	20,691	17,761	69,795

Imports.

		May, 1885.	May, 1886.	May, 1887.
Drugs, unenumerated..	value £	53,592	50,780	59,653
Chemical manufactures—				
Products unenumerated	value £	119,552	96,020	111,277
Alkali	cwt.	5,745	11,726	3,737
,, ...	value £	4,178	6,983	2,809
Brimstone	cwt.	93,177	52,158	59,812
,, ...	value £	23,897	12,473	13,229
Nitre (nitrate of soda)	cwt.	113,606	185,396	396,684
,, ,,	value £	70,914	93,762	209,466
,, (nitrate of potash)	cwt.	31,066	22,854	30,938
,, ,,	value £	27,877	20,312	26,951
Quicksilver	lb.	715,875	782,700	315,000
,, ...	value £	52,498	65,165	27,875
Bark (Cinchona)........	cwt.	9,406	13,158	13,803
,, ...	value £	63,602	66,719	62,938
Gum Arabic	cwt.	9,205	3,243	2,753
,, ...	value £	26,270	13,587	11,700
Lac, seed, shell, stick, and dye	cwt.	16,175	12,168	19,739
Lac, seed, shell, stick, and dye	value £	51,923	34,493	51,179
Dyes and tanning materials—				
Bark (for tanners' or dyers' use)	cwt.	26,090	37,813	48,066
Bark (for tanners' or dyers' use)	value £	11,342	15,895	24,398
Anilin dyes	value £	15,741	11,627	21,833
Alizarin	value £	12,602	21,841	19,586
Other coal-tar dyes....	value £	313	—	75
Cochineal	cwt.	847	544	350
,, ...	value £	5,307	3,193	2,185
Cutch and gambier..	tons	1,522	2,047	1,513
,,	value £	33,422	46,697	35,426
Indigo	cwt.	2,580	855	3,200
,, ...	value £	45,014	19,023	62,263

,, ...	value £	168,203	99,111	72,299

Indian Trade and Navigation Reports.

The Indian trade and navigation reports for April, compared with those for April of last year, show a net increase in the value of imports of 19,12,778 rupees, and an increase in every item of import except under two heads. The net increase in exports was 32,70,649 rupees, and every item showed an increase except chemicals, drugs, medicines, narcotics, and dyeing and tanning materials, which decreased by upwards of 17 lakhs.

A Prize for Chemists.

The Amsterdam Association opposed to the adulteration of butter has offered a prize of 1000 florins to the discoverer of the best method for immediately detecting foreign matters added to butter. The process must trace out any sort of fat that may have been introduced, whether it is harmful or not. The process is to be simple and practical enough to be worked without a chemical laboratory. Memoirs should be sent before January 1, 1888, to Mr. J. Binkes-Borgers, at Leyden. The prizetaker will be allowed to keep his copyright, and may take out patents in foreign countries.—*Chemist and Druggist*, June 18.

The Iodine Convention.

At the commencement of the present year the price of iodine, which had for some time been very low, and was expected to experience a further decline in consequence of the anticipated collapse of the combination of producers, suddenly, and to the astonishment of many dealers in the article, rose to 9d. per oz. The convention of the producers of iodine had been renewed, but the parties interested in it wisely kept their own counsel, and were enabled to reap a substantial benefit as the reward of their discretion. The new convention, to which most, if not all, of the manufacturers and the principal holders of stock in Europe, the United States, and the west coast of South America have acceded, was registered on February 18 at Iquique—the principal port of shipment in the iodine district—now held by the Chilians. The agreement, we understand, has been concluded for a term of three years, commencing on January 1, 1887, and it has been resolved that during this period the sale of the entire product will be vested in one house exclusively. The European manufacturers are to have for their share 40½ per cent. of the total sales effected, so long as the latter do not exceed 336,000lb. If the sales of iodine exceed that quantity—which means about ten months' consumption, and is, therefore, probably to be taken as an annual limit—ninety per cent. of the excess will fall to the share of the Chilian producers.

The parties interested in the convention, in addition to the English and French producers, are divided into three categories, viz.:—

Firms possessing iodine manufactories in working order and holding stock in Europe.

New manufacturers, carrying no stock in Europe.

Owners of iodine holding stock in Europe, who are not at the same time manufacturers of the article in South America.

The parties falling under the first category will be compelled, under the terms of the agreement, to suspend the manufacturer of iodine until their surplus stocks have been cleared off by their share of monthly allotments of sales effected. It is said that some firms hold enough stock in Europe to require two and a half or three years before, under this system, they will be allowed to resume working, and if the estimate of the European stock owned by Chilian holders is correct, this clause will apparently be tantamount to a virtual cessation of iodine production in the old Chilian works during the terms of the convention.

The new producers of iodine, forming the second class of contracting parties, have their output strictly limited to the quantity assigned to them as their monthly share of the orders. Firms who hold stock in Europe, but who do not possess works in South America, have to submit to a fixed reduction on the amount of their monthly share of the sales, in order to recoup the producers for the compulsory limitation or temporary cessation of their output. The producing capacity of all works included in the convention will be estimated, and the share of each contracting party in the orders is to be fixed according to the relation between the producing capacity of his works and the estimated annual consumption. To commence on January 1, 1887, the price for iodine for metallurgical and dyeing purposes is fixed at 6d. per oz., and for all other, including pharmaceutical uses, at 9d. per oz.

The aggregate capacity of production of sublimed iodine of not less than 98 per cent. standard in the South American works at the end of last year was estimated at 25,560 quintals, or 2,591,340lb.; the European stock of Chilian iodine at 10,177 quintals, or 1,032,965lb.; the export of iodine from the South American west coast in 1886 at 3,825·88 quintals, or 388,327lb.; and the world's consumption at 4000 quintals, or 406,000lb. These figures would prove that Chili is at present capable of producing six and a half times as much iodine as is required for all purposes to which the article is applied, and it must not be forgotten that there is at present no prospect of any considerable extension in the use of the article, even though the price should fall to a third or a fourth of that prevailing. The stock of Chilian iodine now held in Europe would alone suffice for two and a half years' consumption, and the convention must therefore necessarily restrict the output of iodine in South America to a very small fraction indeed of the present producing capacity. The directors of the iodine association purpose, it is said, to gradually raise the price considerably beyond their present quotation, and as they control the market at this moment they will probably succeed. But the combination is likely sooner or later to come to grief through the impatience of its own members to submit to an artificial stunting of their producing powers, nor could the collapse of an association based upon principles so essentially vicious from an economical point of view be regretted, however disadvantageous it might be to its own component parts.—*Chem. and Druggist*, June 18, 1887.

Foreign Competition in Brazil.

Consul Cooper remarks on foreign competition in Santos, in the province of Sao Paulo. In this province foreign competition has made but slight impression on the general course of British trade, but the Germans, who are the only serious rivals in the field, have possessed themselves of one or two branches, and are making great efforts to establish the supremacy of their woollen and cotton industries. In face of this opposition the Consul urges concerted action of all the industrial and commercial classes on well-organised principles of trade. "Apart from the low price at which the Germans produce and transport their production, a great secret of German success is their thorough training as mercantile men. German merchants abroad are shrewd, hard-working men, generally of ample education and agreeable social qualities, with broad unprejudiced views, and possessing the inestimable gift of being able to ingratiate themselves with the people with whom they reside and have to deal. In such men the German manufacturer finds solid support, and the most potent means for the extension of trade." Consul Cooper does not think much good will come from relying on the consular service, and suggests, as one among other plans of extending trade, the establishment of commercial and industrial museums or agencies at certain advantageous localities abroad, primarily in new countries.

Monthly Patent List.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

7261 R. A. Gibbons, London. Smoke consuming apparatus for boiler furnaces. May 18

7286 R. W. Anderson, Liverpool. Improvements in means and apparatus for supplying air or draught to the furnaces of steam generators. May 19

7363 C. Tellier, London. An improved apparatus for utilising atmospheric or solar heat, for raising water or other purposes. Complete specification. May 20

7370 W. P. Thompson—From J. A. Sperry, United States. Improvements in amalgamators. May 20

7402 J. Smith and D. Cowan, London. Improvements in steam generators. May 21

7409 A. de Lande Long and C. Watson, Stockton-on-Tees. A new arrangement of regenerative furnace. May 21

7466 T. Nelson, Accrington. Improvements in filters. May 23

7515 C. A. Koellner, London. An improved filtering and lixiviating press. Complete specification. May 25

7525 H. H. Lake—From U. Cummings, United States. Improvements in air compressing apparatus. Complete specification. May 25

7628 H. Walker, Birmingham. Improvements in and connected with steam boiler and other heating, melting, and smelting furnaces, muffles, and the like, for various purposes. May 26

7610 R. Robson, Leeds. Grate bar for boilers and all purposes in raising steam and heating furnaces and such-like. May 26

7716 P. Evans, Liverpool. Improvements in and applicable to steam generators. May 27

7717 J. C. Stitt, Liverpool. Improvements connected with steam generators in which artificial or forced draught is employed. May 27

7723 O. Kruschki, Liverpool. New and improved heating apparatus with air supply from above. Complete specification. May 27

7725 C. W. Guy, London. Improvements in crushing mills. May 27

7726 R. W. Deacon—From W. Maxwell, Java. Improvements in centrifugal drying machines. May 27

7756 H. H. Lake, London—From B. Roberts, United States. Improvements relating to smoke-condensing apparatus for use in connection with steam boiler and other furnaces. Complete specification. May 27

7772 G. W. Allen, Manchester; and H. J. A. Bowers, London. Improvements in apparatus for purifying water for steam boilers. May 28

7815 T. Taylor, London. Improvements in or applicable to steam boilers for consuming smoke. May 28

7817 J. Kroog, London. Improvements in apparatus for automatically discharging water of condensation from steam pipes, and for similar purposes. Complete specification. May 28

7908 A. E. Barthel, London. Gasometer. June 1

7910 J. R. Robson, Leeds. Improvements for increasing and making more effective the heating surface of boiler flues. June 1

7931 W. P. Thompson—From R. A. Marshall. See Class VII.

8050 A. J. Marquand, London. Improved means for preventing corrosion and incrustation in steam boilers and other similar vessels. June 3

8054 G. Little, London. Improvements relating to pulverisers, and to means for separating or sorting pulverised or disintegrated materials. June 3

8179 J. Thiry and G. Chantrenne-Soiron, London. Steam and other injectors. June 7

8180 W. H. Farris, London. Steam generators, circulators, and pulsators. Complete specification. June 7

8285 W. Neilson, H. Neilson, and T. Williamson, Glasgow. Reversing valves for regenerative and other furnaces. June 9

8339 J. T. Collinge, Manchester. Rotary pumps, blowers and exhausters. June 10

8396 A. J. Marquand, London. Electrical apparatus for preventing corrosion of steam boilers and similar vessels, and for removing the incrustation when once formed. June 10

8413 G. H. Steehmann, Manchester. Combined automatic steam-boiler feeding apparatus and feed water heater. June 11

8111 J. A. Yeadon and R. Middleton, Leeds. Machinery for drying small coal or coke, or for desiccating substances of a like granular character. June 11

8192 F. Quénehen and A. Vansteenkiste, London. Apparatus for grinding animal, vegetable, and mineral substances. June 13

8658 W. H. Mirfin, Manchester. Construction of internal furnaces and flues for steam boilers. June 16

8670 W. J. Ellis, Manchester. Centrifugal pumps. Complete specification. June 16

8698 E. A. Cowper, London. Hot blast valves. June 16

*COMPLETE SPECIFICATIONS ACCEPTED.**

1886.

8105 E. Robinson. Apparatus for drying glutinous fibres, granular and other materials. May 25

8107 A. Tolhurst, C. A. Glazbrook and A. Philbey. Fire grates and smoke consuming apparatus for furnaces. May 21

9733 A. G. Meeze. Apparatus for cooling and heating fluids. May 28

10061 H. S. Stewart. Apparatus for exhausting, lifting, forcing, or measuring fluids. June 11

10098 J. Atkinson. Machines for cooling air or other gases. June 11

10378 C. J. Croft and F. Dowling. Apparatus for forcing draught in boiler furnaces. June 15

10595 A. Flamache and E. Pieard. Method and apparatus for desiccating wood and other porous substances. June 1

10663 J. Rankin. Furnace grates. May 28

10704 S. S. Bromhead—From L. Stauffert. Mixing apparatus for liquids. June 18

11244 A. W. Anderson. Filter presses. May 21

1887.

5793 J. King. Apparatus for use in roasting, drying, carbonising, or torrefying farnia, dextrine, manures, feeding stuffs, etc.; for heating, evaporating, or distilling liquids, and for heating disinfectors and water apparatus. June 18

7203 C. T. Schoen. Apparatus for burning liquid fuel. June 18

7363 C. Tellier. Apparatus for utilising atmospheric or solar heat for raising water, etc, June 22

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

7156 J. Keith, Glasgow. Improvements in apparatus for manufacturing oil-gas. May 17

7177 J. W. Corbett and R. D. Hardy, London. Improvements in and in means for the manufacture of gas. May 17

7230 J. E. Barwick, St. Petersburg. A system of heating boilers or generating steam. May 18

7268 A. Hommel, London. Process for obtaining oxygen. May 18

7274 F. V. Hadlow, Buxted. An improvement in the artificial manufacture of coal, so as to render it comparatively smokeless. May 19

7482 R. de Soldenhoff, London. Improvements in or addition to means or apparatus employed in the manufacture of coke for the desiccation and incineration of precipitants or solids resulting from sludge or other substances liable to putrify. Complete specification. May 23

7499 C. Birley and J. Sturgeon, London. New or improved apparatus for automatically regulating the supply of air to the combustion chambers of gas-producers according to the pressure of steam in boilers fired with the gas from such gas-producers. Complete specification. May 23

7518 J. Belou, London. A new or improved process for manufacturing pure hydrogen. Complete specification. May 25

7613 L. Sepulchre, London. Improvements in lighting and heating by mineral oils. May 25

7713 J. H. R. Dinsmore, Liverpool. Improvements in and apparatus for washing and purifying coal-gas. May 27

7711 J. H. R. Dinsmore. Improvements in and connected with the manufacture of illuminating gas from coal. May 27

7751 E. Fleischer, London. Improvements in separating solid matter from smoke or gases resulting from combustion, and apparatus therefor. May 27

7782 W. Defries and V. J. Feeny, London. Improvements in feeding oil for lighting and heating. May 28

7811 W. Backer, London. An improved process of treating tar for the purpose of producing illuminating and heating gas and coke. May 28

8005 H. Keevil, Bath. The more effectual combustion of the oil, and increasing the brilliancy of the flame and light of paraffin, petroleum, and benzoline lamps. June 3

8191 C. L. Baillard, London. Improvements in the treatment or preparation of mineral or other like oils. June 7

8218 E. W. Harding, Greenwich. Improvements in the manufacture of gas from coals, with other advantages in connection therewith. June 8

8392 J. A. C. Mackenzie, London. An apparatus to be employed for heating by means of ordinary gas-burners. June 10

8679 A. G. Meeze, Redhill. Improvements in the manufacture of gas, and apparatus therefor. June 16

8697 H. H. Doty, London. An improved method of and apparatus for generating light and heat from mineral or other oil. June 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

7289 M. Immisch. Apparatus for measuring heat. May 25

7580 C. F. Claus. Purification of coal-gas. May 25

7582 C. F. Claus. See Class VII.

7584 C. F. Claus. Purification of coal-gas. May 25

7585 C. F. Clans. Purification of coal-gas. May 21

9473 J. Livesey and W. Whitehouse. Apparatus for enriching gas by admixture of hydrocarbon vapour. May 21

9598 J. H. Johnson—From E. Delamare-Deboutteville and L. P. C. Malandin. Apparatus for carburetting air. May 28

9658 W. Welch. Means for utilising oils or gases as fuel, and for lighting fires. June 15

10698 T. Thorp. Non-regenerative gas-lighting. June 22

1887.

3267 C. W. Watts. Purification of coal-gas and apparatus therefor. May 28

5574 W. W. Horn—From A. L. Allen. Apparatus for the manufacture of gas. June 8

5863 R. Harrison and W. Oliver. Applying the vapour of volatile liquids as a source of motive power. May 25

6018 A. J. Boult—From D. M. Kennedy. Purifying hydrocarbon oils. May 28

7034 O. W. Bennett and S. O. Hemenway. Carburetting apparatus. June 15

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, ETC.

APPLICATIONS.

7867 W. M. Fraser and J. Snodgrass, Glasgow. Improvements in primary distilling apparatus for shale or other oil-yielding mineral. May 31

8090 F. Lennard, London. Improvements in apparatus used in the distillation of tar or oil. June 1

8623 W. P. Thompson—From R. A. C. von Sehlieben, Berlin. Improved method of separating the chief component parts of coal shale. June 15

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

9550 O. Rose. Apparatus for the distillation of coal shale and other materials. May 25

11131 J. Jones. Retorts for the destructive distillation of shale, coal, and other bituminous substances. June 8

1887.

5785 A. L. Vale—From the Chemische Fabrik Actien Gesellschaft. Process for the purification of crude anthracene. May 21

---

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

7333 F. E. Schmuckert, London. An improved process of preparing indigo solutions for dyeing purposes. Complete specification. May 19

7627 I. Levinstein, Manchester. Improvements in the production of azo colouring matters. May 26

7733 J. Y. Johnson—From The Farbenfabriken vormals F. Bayer & Co., Germany. Improvements in the manufacture of dyes. May 27

7812 A. Liebmann and A. Studer, London. A process for producing a new mono-sulpho acid from alpha-naphtol. May 28

7833 J. Y. Johnson—From the Badische Analin and Soda Fabrik, Germany. Improvements in treatment and preparation of naphthazarine (dioxynaphthaquinone), and the production of a soluble derivative thereof, and the application of the same in dyeing and printing. May 28

8265 S. Pitt—From A. Weinberg, Germany. The manufacture of a new naphtol-disulphonic acid and of dyestuffs therefrom. June 8

8296 L. Paul, London. A process or processes for the production of colours from tetrazodiphenyldicarbon acid, and from its methyl and æthyl ethers. June 9

8381 P. McAra, J. Walker, J. A. Birrell, W. Brock, junr., and J. Adam, Glasgow. Improvements in and connected with the preparing or maturing and treating of cut or reduced logwood and other dye-woods for dyeing and other purposes. June 10

8431 I Imray—From La Societe Anonyme des Matières Colarantes et Produits Chimiques de St. Denis, A. F. Porrier, and D. A Rosenstiehl, France. A process for the manufacture of anthraquinone. Complete specification. June 11

8437 L. Paul, London. Process or processes for producing mono and diamidoazobenzidines, transformation of them into tetrazo compounds, and their combination with amines and phenols (naphtoles), or the sulpho-acids of these bodies. June 11

8501 C. A. Bennert, London. Improvements in the manufacture of colouring matters. June 13

COMPLETE SPECIFICATION ACCEPTED.

1887.

7333 F. E. Schmuckert. Preparing indigo solutions for dyeing purposes. June 22

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

7476 G. A. Hartington, Rochdale. A method of and apparatus for cleaning or separating seed or other extraneous matter from cotton, wool, silk, or other fibrous materials. May 23

7513 T Tschieret, London. Improvement in proceedings and apparatus for felting woollen thread. May 25

7932 G. I. J. Wells and S. L. Howard, Liverpool. Improvements in the manufacture of rhea or other like fibre from the rhea bark or china grass or like products of other plants of the Urtica family. June 1

8011 W. B. Nation and J. J. Worswick. See Class XIX.

8015 E. Jaegermayer, London. An improved method of and apparatus for determining the percentage of clean wool contained in a given quantity of raw wool. June 3

8167 G. F. Wilson, Westminster. Improvements in the method of and composition for treating textile fabrics. June 7

8178 E. Tremsal and A. Dicktus, London. Improvements in the process of scouring wool, and in apparatus therefor. June 7

8575 H. H. Lake—From C. Schrebler, United States. Improvements relating to the drying and carbonising of wool, and to apparatus therefor. Complete specification. June 15

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10053 W. Mather. Apparatus for treating textile materials with liquids, gases or vapours. June 4

10176 H. R. Randall. Treatment of silk cocoons, raw silk, etc., and apparatus therefor. June 11

10250 J. S. Farmer. Apparatus for testing the purity of raw cotton. June 18

10545 A. Mitscherlich. Preparing fibres capable of being spun from wood. June 15

13197 G. Tolson and J. Illingworth. Carbonising wool, rags, etc. June 1

13198 G. Tolson and J. Illingworth. Carbonising wool, rags, etc. June 8

1887.

5685 A. J. Boult—From E. H. M. Caston. Manufacturing a merchantable material from thistledown. June 8

6121 E. W. Serrell, Junr. Process and apparatus for the mechanical "debavage" of cocoons after brushing. May 28

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

7550 E. B. Petrie and R. Wild, Rochdale. Improvements in the means and method of and for the washing, scouring, boiling and bleaching of fibres, fibrous materials and textile fabrics; and the stripping of fibres from hides and skins. May 25

7556 R. Lockwood and E. L. Adamson, Halifax. Improvements in the method of and means for dyeing yarns. May 25

7740 E. Boursier, London. Improvements in dyeing fabrics, and in materials and apparatus therefor. Complete specification. May 27

7911 W. Brierley—From R. Perzina, Germany. Improvements in automatic coppers or vats employed in the dyeing of fibres, and fabrics or pieces. June 1

8333 J. Takmine. See Class XVIII.

8361 J. A. Schofield, London. Improvements in appliances for attaching to lines, cords and rods, textile fabrics for the purpose of drying and bleaching the same, and for other purposes. June 10

8525 J. H. Smith, Glasgow. Improvements in apparatus for drying woven fabrics, yarns, or fibrous materials. June 14

8668 C. T. Clegg, Manchester, H. A. Clegg, Heaton Norris, and F. Lee, Didsbury. Improved machine for new process of dyeing wool or other material. Complete specification. June 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10053 W. Mather. Apparatus for treating textile materials with liquids, gases or vapours. June 4

10542 T. Holliday. Dyeing textile fibres. June 18

10718 L. Harmell, J. Harmell, and A. Harmell. Rotary apparatus for preparing for dyeing combed wool in bobbins. June 22

13261 J. H. Storey, J. Wilkinson, and H. Bateson. Machinery for printing in several colours on paper, oil cloth, and other fabrics. June 22

1887.

5596 J. Bromley and T. Harrison. Machinery for bronzing, colouring, or otherwise ornamenting paper and other material in sheets or rolls. June 8

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

7270 E. W. Parnell and J. Simpson, Liverpool. Improvements in obtaining pure carbonic acid gas, and in apparatus therefor. May 19

7661 W. G. MacIvy, London. A new way of making soda. May 26

7701 C. F. Claus, H. L. Sulman, and E. E. Berry, London. Improvements in the manufacture of soda by the ammonia process. May 27

7859 L. A. Staub, Liverpool. Improvements in the manufacture of carbonate of soda and carbonic acid from the bicarbonate, and in apparatus therefor. May 31

7906 R. Schneider, London. Producing hydrate of baryta from sulphate of barium. May 31

7931 W. P. Thompson—From R. A. Marshall, United States. Improvements in demi-john and carboy cases for acids and other liquids. June 1

8129 L. A. Staub, Liverpool. Improvements in the manufacture of carbonates of soda. June 6

8213 S. Hallsworth and R. Bailes, London. A new or improved method or process of manufacturing ferric sulphate or sesquipersulphate of iron, commonly called nitrate of iron. June 8

8217 G. H. Bolton, J. R. Wylde, and H. Auer, Liverpool. Improvements in or relating to the manufacture of permanganate of soda, or of a mixture of the same with other disinfecting or oxidising matter. June 8

8289 W. Bramley, Middlesbro'-on-Tees. Improvements in obtaining chlorine or hydrochloric acid from chloride of calcium. June 9

8622 L. Mond, Liverpool. Improvements in obtaining ammonia, chlorine, and hydrochloric acid from ammonium chloride. June 15

8666 A. M. Chance and J. F. Chance, Liverpool. Improvements in treating alkali waste to obtain sulphuretted hydrogen, and in apparatus employed therein. June 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

7582 C. F. Claus. Preparation of ammonia compounds from coal gas. June 4

8819 L. A. Chevalet. Apparatus for distilling and purifying ammoniacal liquids. June 11

9208 H. W. Deacon and F. Hurter. Apparatus for producing ammonia from sulphate of ammonia. May 28

10000 A. W. Gillman and S. Spencer. Apparatus employed in the manufacture of sulphites. June 11

10419 G. Jármay. Separating the ammonium chloride from liquors obtained in the manufacture of soda by the ammonia soda process. June 22
1588? W. F. Nast. Treatment of manure and other organic matters, and production therefrom of ammonia and residual products free from ammonia. June 11

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

7151 S. Bunting, Dublin. Improved moulds with apparatus attached for blowing glass by means of compressed air, and completing the manufacture in the mould. May 17
7229 S. Bunting. Improved compressed air apparatus suitable for glass blowing. May 18
7279 J. D. Watson, Glasgow. Improvements in the enamelling of metallic and other surfaces, and in the materials employed therefor. May 19
7516 H. Godwin and W. Hewitt, Hereford. Making and connecting tile or ceramic fenders and ceramic mouldings generally on new and improved principles. May 25
7560 H. M. Ashley, Sheffield. Improvements in the manufacture of internally stoppered bottles and other like vessels of glass. May 25
7609 F. Siemens, London. Improvements in ceramic kilns. May 25
8003 L. A. Holmes, Blackpool. A novel adaptation in the manufacture of plaques for teapot stands. Complete specification. June 3
8016 A. H. Hull, London. An imperishable opal letter for buildings. June 3
8170 J. H. Hughes and J. Holdsworth, London. A new or improved compound or material capable of being moulded and used as a substitute for natural stone or marble, for pottery, metallic, wooden, and other articles. June 7
8235 R. Stuart, London. An improvement in the production of glassware. June 8
8272 G. F. Chance, London. Improvements in the manufacture of rolled glass, and in appliances used in the said manufacture. June 10

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

8677 J. C. Arnall and H. M. Ashley. Manufacture of bottles and other articles in blown glass. May 28
9798 H. Defries. Manufacture of lenses. June 11

1887.

1911 J. Critchlow, T. Forester, W. Forester, H. Forester, and L. Forester. Improved potters' filter-press. May 21
2618 F. Bennett. Earthenware and china plates and dishes. June 1
5698 S. H. Rowley. Preparing articles of glass or pottery to receive metal pipes or other metal connections. May 28
5723 S. Pitt—From G. Falconnier. Manufacture of building materials from glass, and application of the same. May 28
5866 J. Blair. Improvements in china and crockeryware. May 25

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

7178 J. W. Corbett and R. D. Hardy, London. Improvements in and means for the manufacture of cement. May 17
7243 L. G. Knemeyer, London. Cement adapted for artificial stone work, and for coating walls, etc., with a suitable surface for the reception of waterproof painting. May 18
7252 J. Gollings and H. Hicks, London. Improvements in the construction of "formers" for plastic brick manufacture. May 18
7381 J. Dudley and J. Hamilton, Derby. Improvements in concrete and artificial stone mantelpieces. May 20
7411 A. Busch, London. Improvements in the manufacture of cement for building and general constructive purposes. May 21
7539 S. Smith, J. Roberton, and J. R. Andrew, Glasgow. Improvements in making Portland cement. Complete specification. May 25
7708 N. R. Foster, Uxbridge. A new or improved method of constructing kilns and drying floors for the manufacture of cements and limes. May 27
7757 C. Rabitz, London. Improvements in the construction of walls, ceilings, roofs, and the like. May 27
8024 J. Stevenson—From J. Salvat, France. A new process for the preservation of woods. June 3
8266 W. D. Cliff and B. E. Pete, London. A new or improved brick or building block. June 8
8316 C. F. Laspe, London. Improvements in the manufacture of firebricks. June 9
8318 A. Scrutton—From D. B. McLaren, New Zealand. A new or improved manufacture of material or compound suitable for paving. June 9
8139 C. F. W. Doehring, London. Improvements in street and other paving. Complete specification. June 11
8489 W. C. Milton, London. Fireproof metallic plastering. June 13
8618 A. W. Rummage, London. An improved fireproof column and staunchion combined, for building construction. Complete specification. June 15

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

9551 W. F. Reid. Hydraulic cement. May 21

1887.

5723 S. Pitt—From G. Falconnier. See Class VIII.
6283 A. Murray. Manufacture of bricks, mouldings, ridges, etc. June 8
6496 C. Chambers, jun. Brick-making machines. June 8

X.—METALLURGY, MINING, ETC.

APPLICATIONS.

7186 G. Downing—From C. Baily, France. Improvements in means and appliances for supporting the roofs of cuttings in coal mining and analogous operations. May 17
7198 W. A. Baldwin, London. A process of obtaining aluminium from its ores or from aluminiferous earths, or earths containing alumina; and of combining aluminium with other metals. Complete specification. May 17
7278 J. S. MacArthur, R. W. Forrest, and W. Forrest, Glasgow. Improvements in treating ores to obtain gold, silver, lead, zinc, copper and other metals or useful compounds thereof. May 19
7282 G. Hatton, London. Improvements in the manufacture of malleable iron and steel, and in apparatus employed therein. May 19
7283 J. Houlston and M. Croft, London. Improvements in puddling and mill furnaces. May 19
7328 N. S. Burnell, Liverpool. Improvements in galvanising sheet iron or steel, and in apparatus therefor. May 19
7368 R. Chambers, London. Improvements in mill puddling and other furnaces used in the manufacture of iron and steel, and other metals, and for other manufacturing purposes. May 20
7426 A. C. Henderson—From P. L. T. Héroult, France. An improved process for the preparation of aluminium, aluminium bronze, and alloys of aluminium, by electrolysis. May 21
7494 P. C. Gilchrist, London. Improvements in the manufacture of steel or ingot iron by the basic process. May 23
7495 P. C. Gilchrist. Improvements in the manufacture of iron and steel. May 23
7506 The New Portable Electric Lamp and Power Syndicate Co., Limited. See Class XVIII.
7514 C. Akrill, London. An improvement or improvements in chilled grain and steel rolls used in the rolling of iron and steel, and other metallic alloys, which improvement or improvements is or are also applicable to rolls generally. May 25
7519 J. Beleu, London. Improvements in treatment of ores. Complete specification. May 25
7533 F. J. Clamer and J. G. Hendrickson, London. A process of cleaning, preparing, and coating metal plates and other metal surfaces. Complete specification. May 25
7563 F. W. Seaman, Sheffield. Improvements in the manufacture of ingots, bars, and tools of self-hardening steel combined with other steel. May 25
7567 D. Owen, London. Improvements in the manufacture of tin and such like metal-coated plates, and in the apparatus employed therein. May 25
7657 J. Weirich, London. Improvements in the treatment of auriferous minerals. May 26
7730 H. Johnson. See Class XXI.
7761 E. A. Jones and F. F. Jones, London. Improvements relating to the preparation of oxides of iron, and to apparatus therefor. May 27
7785 G. A. Jarvis, Wellington. Improved converter bottoms, plugs or blocks. May 28
7924 W. G. Jackson, London. An improved shield for miners' safety lamps. June 1
7977 R. Marlin, London. Improvements in "pots" employed in coating tin and terne plates, and in apparatus connected therewith. June 2
7998 M. Kennedy and G. Green, Glasgow. Improvements in apparatus for washing ores. June 3
8004 J. Williams, Swansea. Improvements in apparatus or machinery for cleansing terne, tin, or other plates. June 3
8026 E. Dutton, Glasgow. Improvements in and connected with hauling gear for iron and steel works. June 3
8101 J Garvie, jun., London. Improvements in steel furnaces. June 6
8207 H Burrows, London. Improvements in open hearth steel furnaces. June 7
8276 A. L. Dowie, Glasgow. Improvements in treating iron and castings thereof. June 9
8277 W Jukes, London. Improvements in the manufacture of steel and in apparatus connected therewith. June 9
8284 S. P. Thompson, London. Improvements in the electro-deposition of the heavy metals. June 9
8343 W. Pegge, Stoke-on-Trent. Breaking off coals without blasting or wedging. June 10
8347 A. C. Patrick and W. Hunter, Glasgow. Improvements in machinery for bending and for straightening or flattening iron or steel plates or bars. June 10

8426 J. B. Thompson and W. White, London. Improvements in the manufacture of sodium and potassium, and apparatus for the purpose. June 11

8427 J. B. Thompson and W. White, London. Improvements in the manufacture of aluminium and its alloys, and apparatus for the purpose. June 11

8498 L. W. Adamson and W. F. Hall, Newcastle-on-Tyne. Improvements in miners' safety lamps. June 13

8599 E. Walsh, jun., London. An improved method of and apparatus for reducing zinc ores and collecting the metallic zinc therefrom. Complete specification. June 15

8630 W. Muirhead, Glasgow. Improvements in and connected with furnaces for the production of steel. June 15

8705 H. Lawrence, London. Improvements in machinery or apparatus for screening coal, mineral ores, and other substances. Complete specification. June 16

8712 J. Y. Johnson—From A. de Meretens, France. A new or improved process for browning or colouring iron or steel surfaces and protecting them from rust. Complete specification. June 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

8966 D. Owen. Manufacture of tin and other metal-coated plates, and apparatus therefor. June 8

9214 F. F. E. Elmore. Means and apparatus for coating various metal wares by combined electro-chemical and mechanical process. June 1

9345 J. Swift, Sheffield. Apparatus for boring coal, rock, or other mineral substance. May 21

9390 W. B. Ash. Casing for iron and other metals, specially applicable for the metal work of bedsteads and chandeliers. May 21

9432 H. Leipmann. See Class XVIII.

9486 L. Grabau. Production of aluminium and alloys thereof. May 25

9515 D. Davy. Apparatus for moving ingots or blooms into position for passing through the rolls of rolling mills. May 25

9815 J. Pinder and B. Woodcock. Hardening and tempering steel wire. June 4

9919 E. W. Parnell and J. Simpson. Treatment of ores containing sulphide of antimony for obtaining the sulphide in a concentrated form, with any gold or silver present. May 25

9999 T. Archer, jun., and J. Fairley. Means for storing and supplying compressed air for use in mines for ventilating or other purposes. June 8

10185 O. P. H. A. Straube. Method of igniting mining cartridges and discharging firearms. June 11

10594 J. Clark. Obtaining alloys of aluminium with copper or other metals. June 11

11600 A. E. Tucker. Linings of copper, lead, and similar furnaces, and of steel or Siemen's furnaces and steel converters. May 21

1887.

6087 E. D. Wassell. Reducing the point in carbon in steel, and forming a homogeneous weld. June 8

6487 R. L. Short, J. Short, and J. B. Short. A safety lamp for miners. June 4

XI.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

7213 F. Vogel, Manchester. A process for dissolving tallow or other fatty matter in water. May 18

7681 H. J. Haddan—From P. Schroder, Germany. Improvements in apparatus for purifying oil. May 26

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

5960 S. Schofield. Extracting oil from greasy waste, and making same into soap. May 25

6986 W. Sanzenbacher and S. Tanatar. Method and apparatus for distilling fatty acids by means of superheated steam. June 15

XII.—PAINTS, VARNISHES, AND RESINS.

APPLICATIONS.

7159 H. Dell, Brighton. A polish for leather, linoleum, stained floors, furniture, etc. May 17

7376 F. Crane—From J. Hale and W. D. Field. Improvements in lacquers and varnishes. May 20

7377 F. Crane—From J. Hale, United States. Improvements in varnishes. May 20

7521 H. H. Lake—From J. P. Perkins, United States. Improvements in the manufacture of pigment or paint. Complete specification. May 25

7809 G. Harrison and O. Trimming, London. Improvements in the preparation of fireproofing fluids or paints to be applied to textile and other inflammable materials. Complete specification. May 28

8031 R. Gould, London. A new or improved composition for distempering. June 3

8253 F. Crane—From W. D. Field, United States. Improvements in pyroxyline compounds and varnishes, and in the treatment of certain alcohols for obtaining acetates, chiefly applicable as solvents for pyroxyline. June 8

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10960 M. Benedictus. Material for removal of old paint. May 28

1887.

6323 W. L. Wise—From R. Lehmann. Apparatus for the manufacture of varnish. June 14

XIII.—TANNING, LEATHER, GLUE, AND SIZE.

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10987 J. Townsend. Treating hides or skins. June 22

16411 J. H. Lorimer. Apparatus for drying hides, skins, etc. June 8

XIV.—AGRICULTURE, MANURES, Etc.

APPLICATIONS.

7746 T. Darling and J. Ford, Glasgow. Improvements in and relating to machinery or mechanism for breaking, crushing, and grinding phosphate stones and similar hard materials used in the manufacture of manure. May 27

8415 J. L. Wood, London. Improvements in apparatus for distributing "Thanatos" or any other insecticide, moist or dry, on plants, shrubs, etc. June 11

8528 D. McGregor and J. McArthur, jun., Glasgow. Improvements in absorbing moisture from and deodorising fæcal and other refuse matter, and utilising the whole as a manure. June 14

XV.—SUGAR, GUMS, STARCHES, Etc.

APPLICATIONS.

7259 F. Harm, London. Improved process for converting the syrups from sugar manufacture into mono-saccharates. Complete specification. May 18

7813 F. Bosshardt—From G. Bocquet, France. Improvements in the method of filtering and refining sugar. May 28

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10161 H. J. Haddan—From A. Z. Champy, A. N. Champy, and L. P. Champy. See Class XVI.

10181 M. Strasser. Manufacture of artificial gum. June 15

10873 A. Rossi and C. Hellfrisch. Manufacture of gum. June 22

XVI.—BREWING, WINES AND SPIRITS.

APPLICATIONS.

7190 J. Wallace, London. An improved mode of and apparatus for distilling and maturing alcohols. Complete specification. May 17

7277 J. Takamine, Glasgow. Improvements in the maufacture of alcoholic liquids. May 19

7825 W. T. Ramsden and L. Briant, London. Improvements in the method of, and in means and apparatus for, sterilising beer and other fermented liquids. May 28

7883 A. W. Gillman and S. Spencer. Improvements in the preparation of rice to be used in brewing, distilling, and vinegar-making. May 31

7896 A. M. Coyle, E. F. Andrews, and E. C. Davidson, London. Improvements in distillation. Complete specification. May 31

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10161 H. J. Haddan—From A. Z. Champy, A. N. Champy, and L. P. Chamy. Treating the Jerusalem artichoke to prepare it for use in distilling, in the manufacture of glucose, and similar industries. June 8

10722 F. Foster. Machinery for charging liquids with carbonic acid gas. June 22

1887.

7190 J. Wallace. Method and apparatus for distilling and maturing alcohols. June 18

XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, Etc.

APPLICATIONS.

A.—Chemistry of Foods.

8008 T. A. Marshall, Glasgow. An improved preparation of farinaceous substances for use as food. Complete specification. June 3

8298 J. H. Lock, London. Improvements in the treatment, preparation, and preserving of certain alimentary substances. June 9

8664 H. H. Doty, London. A process for preserving eggs in the shell. June 16

B.—Sanitary Chemistry.

7392 H. H. Lake—From C. Lortzing, United States. Improved methods or processes and apparatus for the purification of sewage and for similar purposes. May 20

7482 R. de Soldenhoff. See Class II.

7619 C. J. Bühring, London. Improved means to be employed in the purification of water and other liquids, and the preparation and treatment of materials therefor. May 25

7830 W. Macnab, sen., W. Macnab, jun., and D. Donald, London. Improvements in apparatus for separating by subsidence solid matters from the liquids in which they are suspended. Complete specification. May 28

8357 H. Rimmer, London. Improvements in and connected with the manufacture of material for purifying and filtering water, saccharine, alcoholic and other fluids. June 10

8411 J. Hanson, London. Apparatus to be used in the disinfection, deodorisation, and purification of foul matter. June 11

8528 D. McGregor and J. McArthur, jun. See Class XIV.

C.—Disinfectants.

8063 J. C. Mewburn—From J. J. Bate, United States. Improvements in processes for preserving crustacea and certain new and useful chemical solutions of special utility in such connection. Complete specification. June 4

8217 G. H. Bolton, J. R. Wylde, and H. Auer. See Class VII.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1886.

9733 A. Brin. Treating milk for preserving it. May 25

1887.

3091 E. Wylam. Preparation of food for animals, game, or poultry. May 28

6285 A. R. Leerbeck and J. F. Holm. Producing albumen-maltose dietary malt powder for food. June 11

B.—Sanitary Chemistry.

1886.

8144 H. R. Newton. Drainage and drainage works applicable to towns or country districts; and dealing with sewage and waste waters. June 22

9227 J. S. Lawrey. Means for softening and purifying water. May 25

9569 W. Burns. Manufacture of depurating and decolourising charcoal for purifying sewage and other foul liquids, and for decolourising syrups. May 21

10047 W. Astrop. Apparatus and process for solidifying and drying sewage sludge, etc. June 15

10703 E. Sergeant. Furnaces for treating refuse and materials infected with disease. June 22

13313 R. H. Reeves. Construction and arrangement of apparatus for the ventilation of drains, the deodorising of sewage, and disinfecting gases. June 8

C.—Disinfectants.

1887.

6037 R. D. Hunter. Compositions for treating matters having an offensive smell. May 28

XVIII.—ELECTRO-CHEMISTRY.

APPLICATIONS.

7189 W. H. Akester, London. Improvements in secondary batteries. May 17

7317 J. Kynoch and W. Habgood, London. Improvements in reversible electric batteries. May 19

7360 G. C. Fricker, Putney. Improvements in dynamo-electric machines. May 20

7391 J. A. Kingdon, London. Improvements in primary electric batteries. May 20

7396 C. M. Pielsticker—From F. C. G. Müller, Prussia. Improvements in galvanic elements. May 21

7426 A. C. Henderson—From P. L. T. Heroult. See Class X.

7506 The New Portable Electric Lamp and Power Syndicate Company, Limited. D. Urquhart and B. Nicholson, London. Improvements in and connected with electric batteries and lamps suitable for miners' use or for analogous purposes. May 23

7527 R. M. Hunter, London. Improvements in electric motors or dynamo-electric machines. Complete specification May 25

7553 F. George, Dursley. Regulating the electro-motive force of dynamo-electric machines. May 25

7664 L. N. Loeb, London. Improvements in primary batteries. May 26

7745 R. M. Baily, jun., and A. Grundy, London. An improved construction of dynamo-electric machines. May 27

7865 F. George, Dursley. Improvements in dynamo-electric and electro-dynamic machines. May 31

7975 L. C. E. Lebiez, London. Improvements in secondary batteries or accumulators. June 2

8126 P. A. Fichet and A. Nodon, London. Improvements in chlorine batteries. Complete specification. June 6

8145 D. Skrivanow, London. Improvements in galvanic batteries. June 6

8262 W. M. Mordey, London. Improvements in electric generators. June 8

8267 J. A. Timmis and D. Halpin, Westminster. Improvements in the working and controlling of electric currents June 8

8333 J. Takmine, Manchester. Improvements in the method of and apparatus for bleaching paper pulp and analogous substances by electrolysis. June 10

8443 R. McKenzie—From H. Weymersch, France. Improved electrolytes for electric batteries. June 11

8611 H. Edmunds, London. Improved system and means to be used in the supply or distribution and control of electricity for lighting or other purposes. June 15

8701 J. Ross, Glasgow. Improvements in and relating to the production and application of electric energy for lighting or other purposes. June 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

9082 A. R. Upward and C. W. Pridham. Improvements in galvanic batteries and in their application to electric lighting, etc. May 21

9132 H. Leipmann. Process for treating auriferous substances by electrolysis. May 21

7636 D. J. Fitzgerald. Manufacture of negative elements for voltaic batteries. June 8

8379 A. Reckenzaun. Secondary batteries or accumulators. May 25

8842 E. Andreoli. Plates without support, entirely made of active material, for voltaic batteries. June 8

9478 J. A. Fleming. Dynamo-electric machines. June 22

9514 E. H. Desolu. Galvanic batteries. May 25

9708 A. B. Holmes and J. C. Vaudrey. Apparatus for automatically making and breaking circuit for a dynamo charging accumulators; and for use in running several compound-wound dynamos in parallel circuit. June 22

9991 H. Aron. Electric batteries. June 4

10600 J. E. Rogerson, J. G. Statter, and J. S. Stevenson. Electric furnaces or heating apparatus. June 22

1887.

5687 W. P. Thompson—From H. W. Spang. Fusible connections for armatures for electric generators. May 21

6828 E. T. Higham and D. Higham. Regulation of dynamo-electric machines. June 22

6829 P. Jensen—From O. Lugo. Electric batteries. June 11

6869 H. H. Lake—From W. J. Ludlow. Primary and secondary batteries. June 11

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

7226 R. C. Menzies and C. M. King, Glasgow. Improvements in preparing safety paper for cheques or other documents. May 18

7738 The British Xylonite Co., Limited, and L. P. Merrian, London. A novel xylonite celluloid or pyroxylin fabric suitable for making shirt fronts, collars, cuffs, hats, and bonnets; and for other purposes. Complete specification. May 27

7980 K. Klic, London. Improvements in the preparation or treatment of paper for drawing purposes. June 2

8011 W. B. Nation and J. J. Worswick, London. Improvements in the treatment of vegetable fibres suitable for paper-making, spinning, weaving, and other analogous purposes. June 3

8391 J. Craig—From C. J. Stanbold, Saxony. An improved manufacture of bowl-paper. June 10

8591 R. Wood, Glasgow. Improvements in apparatus for straining paper pulp and the like. June 15

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

7901 C. Weygang. Waterproofing and sizing paper and suchlike material. June 8

8118 C. Morfit. Manufacture or treatment of paper. May 21

8193 A. Wilkinson. Manufacture of paper pulp and papier mache. June 1

9358 E. Musil. Preparation of paper for bills of exchange, cheques, etc. June 22

9874 A. M. Clark—From La Compagnie Française du Celluloid. Colouring, or producing coloured designs on, celluloid and analogous products. May 21

9885 R. Kron. Machinery for grinding, mixing, sizing, dyeing, and otherwise preparing materials for the manufacture of paper. June 1

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

7501 P. G. W. Typke, London. The utilisation of by-products resulting from the manufacture or production of certain phosphorus compounds. May 23

8387 J. Tranbe and G. Bolander, London. Improvements relating to the separation of fusel or ethereal oil from substances containing the same. June 10

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10281 A. Knoll. Process for the production of the ethers of morphincarbonic acid. May 25

10387 A. Knoll. Process for producing methyl-morphin (codein), ethyl-morphin, and the higher homologues of morphin. May 28

XXI.—EXPLOSIVES, MATCHES, ETC.

APPLICATIONS.

7453 T. A. Velschow, London. Improvements in submerged mines and in apparatus for operating or controlling the same. May 21

7603 G. S. Speneer, London. Improvements in and relating to detonating signal apparatus for railways. Complete specification. May 25

7608 H. H. Lake—From Wohanka & Co., Austria. Improvements in the manufacture of explosives. May 25

7730 H. Johnson, London. Improvements in cartridges for blasting coal and other minerals, and for other like purposes. May 27

7742 E. P. Leresche, London. Improvements in or applicable to the exploding arrangements of automatically ignited-submarine mines or torpedoes. May 27

8067 T. G. Hart, Bath. Improvements in explosives for use in firearms. June 4

8109 C. V. Boys, London. A new luminous signal or firework. June 11

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

8736 C. J. D. Oppermann. Detonating fire alarms. June 15

1887.

3920 A. J. Boult—From L. Bagger. Igniting explosive charges and combustibles. May 25

5883 F. W. Smith—From Messrs. Klée and Koecher. Construction of exploding charges or cartridges. June 1

5899 P. M. E. Audouin. Improved explosives, and manufacture of same. May 25

NOTICES.

Comment having been made on the delay in reprinting the numbers for January, 1882 and 1883, the Secretary begs to inform those whom it may concern, that the delay is due to the fact that up to the present not more than twenty orders for those numbers have been received. It is hoped that this notification may stimulate those who desire to complete their sets, to make early application with a view to expedite the consideration of the question of reprinting by the Council. Notice is also hereby given that the numbers for January and February, 1886, being exhausted, no orders for those copies, nor for complete sets of Vol. V., can be executed.

Authors of communications read before the Society or any of its Local Sections are requested to take notice that, under Bye-Law 43, they cannot receive the prescribed 50 copies of their communications unless they comply with the condition laid down in that Bye-Law—viz., that they give notice of their desire to receive such copies upon their manuscript before sending it to the Editor. Mention should also be made as to whether the Discussion is to be included in the reprint.

CHANGES OF ADDRESS, ETC.

Sir Wm. G. Armstrong; address letters, etc., in future to Right Hon. Lord Armstrong.

J. H. Beckingham, l/o Royal Insurance Buildings; Messrs. Scott Bros., Dean Street, Newcastle-on-Tyne.

R. Cameron, l/o Blantyre; 31, Westbourne Gardens, Kelvinside, Glasgow.

A. Campbell, l/o Harold Road; 42, Whittaker Road, Upton Park, Essex.

J. N. Cuthbertson; address letters, etc., in future to Sir John Neilson Cuthbertson.

H. Doulton; address letters, etc., in future, to Sir Henry Doulton.

Wm. Galbraith, l/o Glasgow; c/o Shelton Iron and Steel Company, Limited, Stoke-on-Trent.

F. Goddard, l/o Clipstone Avenue; Pelham Crescent, The Park, Nottingham.

Agnew Griffith, l/o Blundell Sands; 186, High Park Street, Liverpool.

T. G. Hart, l/o Royal School of Mines; 103, Walton Street, Chelsea, S.W.

Sir James McGarel-Hogg; address letters, etc., in future to Right Hon. Lord Magheramorne.

T. W. Lovibond, l/o Newark-on-Trent; Tyne Brewery, Newcastle-on-Tyne.

E. G. Marks, l/o Bristol; c/o Rev. R. Marks, Norton Vicarage, near Gloucester.

J. McKinlay, late of Charing Cross; 2, Woodside Crescent, Glasgow.

Jno. Moss, l/o Lawrence Pountney Lane; Wilson Street, New Cross Road, S.E.; and Hirdir Lodge, New Thornton Heath, Surrey.

T. R. Ogilvie, l/o Snaresbrook; Mill Lane House, Plymouth, Devon.

T. Royle, l/o West Ham Park; Dalton House, Upton Lane, Forest Gate, E.

F. B. Stone, l/o Plumstead; 1, Norfolk Villa, Picardy Hill, Belvidere, Kent.

Dr. L. T. Thorne, c/o Aberystwith; 52, Fortess Road, London, N.W.

H. H. Townsend, l/o Cotham Park; 11, Elgin Park, Redland, Bristol.

Jno. Warwick, l/o Rye Hill; 11, Ashfield Terrace West, Newcastle-on-Tyne.

A. J. Watts, l/o South Hampstead; Caixa 130, Pernambuco, Brazil.

L. J. Whalley, l/o Fairlop Road; Ash Villa, Fillebrook Road, Leytonstone, E.

A. Wuth, l/o Ramsbottom; retain all communications until further notice.

Death.

Jno. Williamson, of Jarrow Chemical Works, South Shields—at Lake Como, July 9.

PROCEEDINGS OF THE SIXTH ANNUAL MEETING.

The Annual Meeting was held on Wednesday morning, July 13th, at Eleven o'clock, in the Chemical Theatre of the Owens College, Manchester. The chair was taken by the President, Mr. David Howard, who called upon the General Secretary to read the minutes of the last meeting. After these had been duly confirmed the President read letters of apology for non-attendance from Sir H. E. Roscoe, M.P.; Mr. J. J. Coleman, chairman-elect of the Glasgow Section; Mr. J. C. Stevenson, M.P.; and Sir Isaac Lowthian Bell, F.R.S.

The General Secretary then read the Report of the Council.

REPORT OF THE COUNCIL.

The Council has the satisfaction of reporting that the number of members on the register is 2302, as

EDWD. RIDER COOK.

---

compared with 2271 at the last Annual Meeting. During the year 213 new members have been elected, and 182 members have been removed by death, resignation and other causes, showing a net gain of 31. Having regard to the continued depression in the Chemical Industries, and the raising of the Society's subscription to 25s., this progress, though small, is a matter for congratulation.

Among those whose death we have to record are Professor Ripley Nicholls, of the Massachusetts Institute of Technology; Colonel Sir Francis Bolton; M. Emile Leroy, Director of the Alkali Department of the famous Glass Works of St. Gobain; Mr. G. T. Chinnery, killed by a disastrous explosion at the Redheugh Tar Products Works in December last; and Mr. J. M. Roberts, of the well-known firm of Roberts, Dale & Co., of this city.

The papers read before the various Sections show a further increase this year. Manchester heads the list with 29, London 21, Glasgow 19, Liverpool 13, Newcastle 8, Nottingham 4, and Birmingham 4; making, together with three communications, a total of 101, as against 82 last year.

On the 30th of October last the Council affirmed the desirability of giving information in the columns of the Journal on foreign statistics, alterations in tariffs, customs regulations, patent laws, and new openings for trade. Accordingly the first Trade Report appeared in November, and has been continued from month to month ever since. The Council would welcome any suggestions tending to increase the value of these reports.

In consequence of joint representations from the Committees of the Glasgow and Manchester Sections, it was resolved in January last to meet in Manchester this year in order that members might have an opportunity of visiting the Royal Jubilee Exhibition, and to defer the meeting in Glasgow until next year, when there will also be an exhibition in that city.

In February, at the request of Sir Frederick Abel, the Council empowered the President, in concert with the Presidents of the Chemical Society and Institute of Chemistry, to take action in furtherance of the scheme to found the Imperial Institute, and an appeal was made to the members at large for subscriptions in aid of the project. The Council trusts that the Imperial Institute will be successful in promoting the happiness and prosperity of the people of the British Empire.

In the same month it was determined to refer the question of the spirit duties and their effect upon the Chemical Industries to the General Purposes Committee. The Council invites members to render such assistance and information on this most important subject as will enable the Committee to effectively deal with the question.

The Council is happy to be able to report that owing to the increase in the subscription sanctioned last year, together with economy in the publication of the Journal, without in any way detracting from its efficiency, the finances of the Society are in a satisfactory state, as will be seen from the Treasurer's Report. This condition of prosperity, nevertheless, must not induce members to spare a single effort to increase our numbers, both for the sake of the Society and for the good of the Chemical Industries.

Mr. J. Carter Bell moved that the Report be adopted.

This motion, seconded by Professor J. Campbell Brown, was carried unanimously.

The Report of the Treasurer was then read.

The Secretary also read a letter from the Honorary Treasurer, regretting his inability to attend, and stating that financially the Society was in a stronger position: but that, in regard to new members, only 213 had been elected since the last meeting, as against 266 in the corresponding period of 1885 and 1886. He also urged members to endeavour to induce their friends to join the Society, so as to maintain the rate of increase.

ELECTION OF OFFICERS AND COUNCIL FOR THE ENSUING YEAR.

The scrutineers appointed to examine the Ballot Lists were:—Dr. Bailey, Mr. Wm. Thomson, Mr. F. Baden Benger, and Mr. Batty. Whilst the votes were being counted the President delivered his Address.

THE PRESIDENT'S ADDRESS.

In past years the Presidential Addresses have been, in most part, devoted to the study of some one branch of chemical industry, and it would be difficult to find monographs, more fully and clearly setting forth the progress which has been made in recent times in the various branches of industry with which they have dealt. If we wish for information on the sudden development which has taken place in the science of explosives, after remaining almost stationary since the time of Friar Bacon; or on the varied interests of the great soda industry, the earliest and most important of the great chemical industries; or on the magic art which has transformed what was but the waste of the gas-works a short thirty years ago, the despair of the utilitarian chemist, the very type of hopeless waste, into a marvellous chromotrope of colours of ceaseless variety, giving a practical meaning to the labours of Hofmann on the ammonias, of Kekule and others on the benzol hexagon, that in their untiring efforts for pure knowledge they never dreamt of,—we cannot do better than turn to the pages of our Journal, and in those addresses trace the progress of these great industries.

I do not propose to adopt the same course, or to attempt to deal exhaustively with one subject, but rather to consider less profoundly, but more widely, the scope of our Society and its operations, not indeed attempting to exhaust the subject, for I am proud to feel that it is far too wide to be included in one short address.

It would be difficult to avoid a certain discursiveness, with the admirable illustrations of the varied progress of chemical industry that are afforded us by the Exhibition we see here. It is true that the last fifty years have not seen the first beginnings of by any means all the branches of these industries, but there are few in which that period has not witnessed new departures of progress, which in very many instances have created new industries rather than merely improved the old. Yet, when we study these varied illustrations of the progress of applied chemistry, we must at once be struck by the different stages which have been attained. There is first the purely empiric stage, where science has no part, but where ruled supreme the art and mystery of the trade, to use the term so familiar in old time, and so expressive of the stage arrived at.

Do not let us undervalue this stage, it is marked throughout by perfection of individual skill, the processes were indeed often imperfect and wasteful, handed down from one to another by laborious apprenticeship, the teacher not knowing himself the secret of his own skill; and yet for all that, the result was often all that we can hope to attain with fuller knowledge and accumulated experience. It is a true sense of the real meaning of this word art that has led those whom we now call artists to steal the word for themselves alone, leaving us, who have as much need as they of true art in our work, with no word to express it; and this is all the more to be regretted, as the alternative word craft has fallen as much in society as the other has risen. The mischief is done, and it is in vain for a Carlyle to tell us, however vigorously, that every maker is indeed a poet, or to bring back any other lost meaning to a word; yet it is a great evil that we should in great measure, while losing the word, have lost sight of the importance and dignity of the art of manufacture, for indeed in the linking of that art to science, instead of to mystery, lies the true hope of advancement in our work.

It is well, therefore, to bear in mind how these excellent results were attained, that we may not lose what is well worth preserving in the industry of the past, while making the fullest use of the opportunities of the present. It is indeed difficult for us fully to realise what it must have been to carry on an investigation with no science to direct its course, or to give any certainty to anticipations as to what lines of research were worthy to be followed out, and where we might hope for successful results, and without even in the simplest matters any certainty *à priori* that a result must of necessity be impossible.

There is indeed much of guess work in the earlier stages of an investigation now, but then there was nothing else, nothing but patiently feeling the way by the simple process of trial and error, till the instinctive judgment born of experience alone, by a process of unconscious cerebration that it is impossible to trace, has laboriously felt its way to its goal.

There are few more curious mental problems than this unconscious reasoning upon long experience. It is often unerringly true as long as it remains unconscious, yet if the possessor of it tries to explain his skill, his attempt will in most cases be so wide of the mark as to throw doubt upon his possession of any skill at all. A shepherd can often guess with surpassing accuracy what the weather will be, yet ask him why he says it will rain, and he will, if wise, give no answer; if he does it will probably be misleading. We hear much of poisoned wells in the histories of the epidemics of the Middle Ages, or indeed in those of the late outbreak of cholera in Italy. The instinct was right, the wells *were* poisoned, but by dirt, not by malice.

It is easy to multiply examples of results of marvellous excellence, attained by this laborious process of unaided experience, in the most varied branches of human workmanship—results so excellent that applied science cannot hope to do more than imitate the materials and workmanship. Damascus blades or early Nankin china are still the standards beyond which we have not progressed; and artistic skill cannot emulate the perfection of Greek statuary, nor can all our anatomy teach a truer knowledge of the possibilities of the human form, than had the unscientific Greek; and great as is our progress in knowledge of applied mechanics, and of the strength of materials, our architects cannot try bolder flights than those of mediæval architects with experience alone to guide them.

Perhaps some of you may think that we have so far outgrown this elementary stage of progress upon which I have dwelt, that it is but a waste of time to study it, but I am sure that just in proportion as we study the later developments of progress we shall see that through them all there has been need for the same patient care that inspired the workers of the past. Doubtless just in proportion as our science is complete and perfect, we can dispense with the laborious processes that led to progress in the pre-scientific stage, but we never shall reach a point where we can dispense with careful and accurate application of science.

The next stage of development in which the general outlines of science having been grasped, and what we now consider the merely elementary laws of combination and substitution, of simple and double electric affinity as they were then called, were placed at the service of the practical man, and when analysis had become a science and not mere guess work, was naturally a most rapid one. From this stage, manufacturing chemistry, as we now understand it, may be said to begin. It is well worth studying the chemical literature of that period, to appreciate what a flood of light science poured upon those who had been groping in the dim twilight. We assume the law of atomic proportion as the simplest matter of course, yet a life-time has hardly passed since Dalton's enunciation of his law.

All seemed plain, then, in practice as in theory, yet in spite of the great advance there was a need almost as great as ever of the patient observation and experimental verification of even the simplest matters. The practical man had then, for example, as the student has now, to find out that soluble and insoluble are at best relative terms (if, in fact, there be such a thing as insolubility), and to work out with infinite patience all that mass of practical knowledge which we daily take advantage of.

Perhaps no branch of industry suffered a greater check in its scientific development than agriculture. Here, at any rate, all seemed clear—burn the plant, analyse the ashes, add the right constituents to the soil; nothing could be simpler—yet the life labours of Gilbert and Lewis have not yet fully solved the problems that seemed to less thoughtful minds so simple. But the failure in practice of much that claimed to be the teaching of science has added to the prejudices apparently inherent in the agricultural mind, and undoubtedly retarded the adoption of real improvements.

Very many of the chemical industries have not advanced beyond the stage in which elementary rather than advanced science is taken advantage of, and in all these there is evidently great scope for progress; in some, on the other hand, all the resources of science have been brought to bear, and progress must be looked for in science itself before we can expect it in practice. Perhaps the most brilliant example of such full application of scientific research is to be found in the great colour industry. If we study the pages of abstracts in our Journal under the head "Colouring Matters, Dyes," we may be inclined to ask if all this is really industrial chemistry, or if much of it is not pure science of no practical interest, yet great pains are always taken to include nothing that is not either actually of practical value or promising to be so.

As a study of industrial progress we must remember that here, too, most admirable results had been attained before the aid of science was called in. The old craftsmen who practised the art and mystery of dyeing, with madder-red or lac, achieved results as brilliant and even more permanent than their scientific successors, and we can make no greater mistake than to suppose that even in this art nothing is now needed but the mere appropriation of scientific research. If anyone were to imagine that nothing was needed but abstract science to prepare the varied colours that meet the ever varying demands of fashion, he would need but little experience to find that, on the other hand, the scientific craftsman succeeds just as much as he preserves all that was valuable in the older system, accurate knowledge of manipulation, patient study of the effect of small and apparently trivial variations of a process, and, above all, that chief characteristic of genius, an infinite capacity of taking pains. The seeming facility of the adept is the fruit of the profoundest study of applied as well as of pure science.

In urging forward, therefore, in the path of scientific industrial progress, which we are bound to do till in all branches of industry all scientific progress is fully appreciated; while valuing most fully the advantages afforded us by science, we shall ever do well to avoid what is perhaps a natural inclination to regard with a feeling akin to contempt the long experience treasured up in traditional rules. Exactly the same process of careful induction and verification is needed in the application of science to practice, as in the developement of science itself; we must never regard the work of the scientific chemist as the terminus *ad quem*, but as the terminus *a quô*, and starting therefrom we must work out for ourselves the application, all the more carefully if the way seems perfectly plain.

Let no student suppose that the knowledge, however perfect, of theoretic results, or practical results either, will ever make him a practical chemist, unless he has learned the method of research as well as the results of research.

The experience of practical life is but too full of instances where, even though the scientific aspect of a problem seems quite plain, some unnoticed, or, it may be, undiscovered factor, upsets all our calculations, and we have need of all our patience to work out our seemingly simple problem. And instances numberless abound also where scientific knowledge is yet imperfect, and where we need all the teachings of long practical experience to enable us to make progress. Yet it is on this borderland between the known and the unknown that applied science can in the future hope to gain the greatest triumphs, and it is just here that scientific training and research, at once scientific and practical, can most avail. But the first requisite of progress here, also, is the fullest and most careful study of what is found by experience to give practical results; devoting our science to understand practice rather than attempting too soon to make practice fit with science.

The great danger to the modern student lies in the very fulness of knowledge ready to his hand. There is no small risk that some may devote all their energies to merely acquiring knowledge, and falling into the snare of imagining that a living dictionary of science, pure or applied, is a practical chemist. The knowledge of the work of others is often sufficient to enable a student to pass examinations brilliantly, but will not in itself enable him to undertake practical work; it may even be an evil to him by producing an arrogant habit of mind, leading him to think, if I may quote the words of a well-known epigram, that "what I know not is not knowledge," and that if facts do not fit with his theory they must be made to do so. It were better far for him to have learned how to work for himself, even if he had learned less of the work of others.

We must bear in mind, moreover, that applied chemistry is never pure chemistry; the application of theoretic knowledge involves invariably questions of physics and mechanics, and the study of these is almost as much a part of chemical industry as is that of chemical science itself. In fact, very often the successful development of chemical theory in practice is entirely a question of these allied branches of knowledge.

The production of pure iron might seem a purely chemical problem, yet in the great strides that have been made in that direction, chemistry seems to fall into the background. The successful working of the Bessemer process involves not merely most interesting and obscure problems of chemistry, but even more of physics and thermo-chemistry, and is itself a triumph of engineering skill; while in the Gilchrist-Thomas process, which has given the full development to Bessemer's discovery, the apparently easy, yet most difficult, problem of burning off phosphorus is solved by an application of chemical engineering in the basic lining of the converter, the simplicity of which is the highest proof of genius.

It would be easy to multiply examples. I will only add one that has recently come under my observation in the Brin process for producing pure oxygen by the use of baryta as a carrier, where the whole question of success turns upon the engineering rather than upon the merely chemical side of the question. It is hardly necessary to point out how great an advantage to chemistry a supply of pure oxygen at a reasonable price must prove, if the process, as appears to be demonstrated already, is capable of ready and economical application.

A glance at the variety of the products in the Chemical Section of the Exhibition shows how wide a field is now claimed for chemistry, and yet even the most careful classification cannot include all the directions in which chemistry has found or should find an application.

Even the twenty-four heads under which the abstracts in our Journal are divided, do not always include readily all the subjects that belong to us, yet even in those industries which are undoubtedly within our field, we find not a few branches where as yet chemistry is but imperfectly applied, where still the empiric stage has hardly yielded to strict science, and others where processes really chemical are carried on without even the attempt to bring science to bear upon them. We ought not to rest content till scientific study and scientific practice has pervaded every industry where chemical action is involved, and though this may seem to open up an over-wide field, where can we stop short of such a claim?

It is true that the statute law gives us a simpler, if narrower definition of a chemist, and visits with pains and penalties every one who so calls himself who has not passed the due examinations prescribed by law for those who practise pharmacy. The very fact that the name of chemist has been monopolised by the wisdom of our Legislature for those practising one branch—the most ancient indeed, but certainly not the only branch of the science—is a curious proof how little this all-embracing character of chemistry was recognised, even as late as the date of the Pharmacy Acts. Such a claim is not even historically accurate, though it has its origin in the history of our science. The older chemists had a wider field, and they aimed at gaining wealth as well as health for the adept, and for generations, countless lives were spent in the twofold searches for the elixir of life and the philosopher's stone, and though often we seem to find but one object of search, it is only when imbued with quaint mysticism, they held that one supreme medicine must suffice to heal the diseases, and refine the constitution of the macrocosm and of the microcosm alike; turning imperfect copper into royal gold and sick lead into healthy silver, by the same power that could give back health and strength to suffering man.

We as the inheritors of their accidental successes, though we have outgrown their system, and have a truer knowledge of the workings of nature, can yet ask no wider field of aspiration than the health and wealth of mankind, and thus we find their objects most comprehensively embrace all of ours—at any rate, if we take them in a Benthamite sense, as the wealth and health to the greatest possible number;—the practical applications of the science of explosives, for instance, from the time of Roger Bacon to our own, has not always tended to the health of the individual.

As, however, our alchemical predecessors found the human constitution less refractory than that of the metals, the art of the chemist came to be regarded almost exclusively as applicable to the productions of powerful medicinal agents, and the value of his labours in dealing with inanimate nature was for a time almost forgotten. In spite, however, of parliamentary draughtsmen, our science has made good her claim to provide for the wealth as well as for the health of mankind, and it is most encouraging to see in how many directions the energy of the local sections of our Society reflect the many-sidedness of science. Of the importance of the papers that we owe to that energy there can be but one opinion, and time would fail me to review, even hastily, all the subjects dealt with. I can but touch upon a few as illustrating the wide scope of applied chemistry, and the methods by which progress has been secured.

Though we may not acknowledge the claim of pharmacy to monopolise chemistry, there can be no doubt that pharmaceutical progress is chiefly to be won by the assistance of chemistry. The work in this direction is no doubt chiefly done by those who devote themselves to pharmacy, and it is in the pages of the journals specially devoted to that subject that we must seek for the record of it. But though it would be an unnecessary repetition to reprint in our Journal what is already accessible to those interested, we have a right to regard that work as part of the subject that we are dealing with. There are few subjects more interesting either to the scientific or to the practical chemist than the active principles of plants. It is true that their investigation is beset with difficulties, the delicate structure of their complex molecules calls for the most careful manipulation in dealing with them, while the properties of many of them render their isolation and study a matter of the greatest difficulty, yet their study is of the highest theoretical interest and practical use. There are few more important needs of the pharmacist than accurate methods of analysis to enable him to standardise the drugs he employs, accurate observation and botanical knowledge may determine with certainty the authenticity of the drug and its condition and probable value; but such knowledge is rather qualitative than quantitative, and in many, or indeed most, instances the most accurate observer can but guess at the relative strength of a drug without analysis. Where accurate methods of analysis have been brought to bear, it is most surprising how very greatly the active principle of a pant varies. It is hardly necessary also to point out the great importance of this analytical study of all cultivated medicinal plants, to guide the grower in the choice of plants and methods of cultivation much has been done in this direction, but much more remains to be done, as also in the separation of active principles that they may be administered without the needless, or even harmful, accompaniments that must be found in the simpler galenical preparations. The study of the natural alkaloids in particular, has not only enriched science with a class of bodies of endless interest and opened out fields of research of the highest promise, but has been of the greatest practical benefit to the human race. I would specially recommend to the notice of those interested in these questions the very valuable paper on the alkaloids, communicated to the London Section by Professor Armstrong, which gives in a concise form much of the latest developments of knowledge of these bodies, and of the light thrown by recent researches upon their constitution. Owing to the great complexity and ready destructibility of these molecules, their synthesis appears so far to have eluded research except in the case of coneine, though there has been a partial success in other cases, as in the methylisation of morphia and benzoyl ecgonine forming codeine and cocaine respectively. Researches in this direction are of the highest theoretic interest, but whether they will ever bear fruit industrially in the production of the natural alkaloids is another question. When we see what can be done by skilful cultivation, guided by analysis, in increasing the alkaloidal contents of certain plants—in the case of the cinchonas, for instance, some of the Java barks yield 10 per cent. and upwards of quinine—it must be doubtful if the synthesis in the laboratory of nature may not prove more economical than that which can be effected in the laboratory of the chemist. Indirectly, indeed, such researches have already borne fruit in the discovery of a class of alkaloids not found in nature, but possessing therapeutic properties peculiar to themselves and of high value.

Another branch of this subject treated of in the same paper is of the highest interest. No branch of modern science has proved at once more fascinating and more fertile in results than that of micro-organisms. Our conceptions of decay and putrefaction have undergone a fundamental change, and what wise men guessed as to the nature of disease have proved to be certain truth. The result of these researches, moreover, has brought the question within the scope of both theoretical and applied chemistry. Not only does this consideration of these organisms indirectly govern all considerations of sanitary chemistry and of the preservation of food, but we find that among them are potent chemists transforming harmless bodies into terribly poisonous alkaloids, and in the case of pathogenic organisms of disease, acting on the human frame not merely by their presence, but by the chemical changes that they bring about. Closely allied to the medicinal applications of chemistry is that of the water supply, not all great towns and still less all villages are as fortunate as Manchester in natural sources of supply, or as much in earnest to obtain the best. The question is not merely one of engineering, as would seem to be the official idea, if we may judge from the qualifications of those appointed as water examiners, nor even of chemical analysis, great as is the progress made in that branch of science, but also of the chemico-biological problem of the organisms present and their results. In our Journals we have most interesting accounts of work done in this direction in the papers of Dr. P. Frankland and of Professor Bishoff, and in the discussions thereon. The subject is yet in its infancy; those who have worked most in the field know best how much remains to be done, but we can already recognise the value of the results obtained, and the promise of a brilliant future for these investigations.

The other end of the question of water supply, the disposal of sewage, has occupied the attention of chemists numberless both within our Society and without. So far the practical aim of the engineers and the chemist is to get sewage safe into the sea, or into a river large enough to take it without notice, with as little chemical treatment as will prevent micro-organisms making their presence too offensively felt. If this is the best we can do it is certainly a reproach to science, but at present the engineers seem unable except in a few cases to cope with the question of irrigation, while the successful precipitation of the most valuable constituents of the sewage seems a chemical problem, almost as hopeless as the philosopher's stone.

Micro-organisms have other claims on the attention of the industrial chemist. The study of fermentation in all its branches, resolves itself more and more into the study of micro-organisms and their life products. Here again we may find in our Journal evidence of what has been done, and may yet be done. It is most interesting here also to observe what accurate results have been obtained by accumulated experience, with no knowledge of the causes at work, though it is needless to point out how impossible improvement must be to those who are bound by mere empiricism, unless they are prepared to face endless failure.

In agriculture, again, we find that the same unnoticed, yet most powerful agents, are at work, and must explain problems hitherto obscure. The papers of Warington, read before the Chemical Society, on nitrifying organisms of soils, gave the history of a research not only valuable in its results, but as a pattern of method, in them we may trace the accurate induction that demonstrated the presence and history of the nitrifying organism with perfect certainty, before ever it had been actually identified, affording an example of indirect evidence of great interest.

Perhaps it is premature to decide whether it is sufficiently proved that to another branch of the same family is due the slow fixation of nitrogen in soil. The question is of the greatest interest; it is difficult to believe that no such process is going on, and that there is no repair of the incessant waste of the nitrogen in the soil, yet the researches of Dr. Gilbert, carried on with the greatest accuracy, have failed to trace any such in the growth of crops.

The great progress which electro-chemistry has made, and is making, affords another instance of most valuable aid already given, and far more promised to chemistry by a kindred science. Electrotype processes of all descriptions have long been worked out, and it is needless to speak of them unless it be to call attention to the interesting development of photogravure. A very interesting paper, read at Nottingham, by Professor Bothamley, giving the results of recent experiments in the use of dyes in correcting the fundamental defect of all ordinary processes of photography, the inaccurate tendency of colours, gives a brief description of the new process of combined photogravure and chromo-lithography, by which it is hoped to solve the problem of photographing in colours, at any rate in part.

The metallurgical applications of the electric current are, however, far wider than the electrotype process. In many cases inventors are working processes not yet divulged, trusting to the protection of secrecy rather than that of the patent law, but there is no doubt that its use in the separation and recovery of metals is capable of most extended application. Great results have also been claimed for the electric furnace, amongst others the cheap production of aluminium. Our past president, Mr. Weldon, whose loss we cannot sufficiently regret, clearly showed that in no other direction can we hope for the direct reduction of that metal; but it remains to be seen if the reduction of the price of sodium by such processes as that of Kestner described by Mr. Mactear, will not be even more effectual in supplying aluminium at a cheap rate. And not only in metallurgy, but in other branches of technical work, the cheapened production of the electric current, which we owe to the attempts to provide economically the electric light, have led to applications in other directions. Much of the work done has no doubt been tentative, but there is no doubt that we have here one of the most promising fields for research.

It has sometimes been remarked that analysis occupies too prominent a position in the Journal. In this view I for one cannot agree; anyone who has had much experience of practical work, knows the value of any method or apparatus that can facilitate the multifarious analyses that scientific processes of manufacture involve, and many of the processes and apparatus described are not merely valuable in themselves, but suggestive of application in other directions. It is no doubt true that too great a multiplication of appliances is undesirable for a student; it is a real misfortune for him to become dependent upon elaborate apparatus, if, as often happens, he finds himself called upon to work with imperfect tools, and when he is called upon, as every practical man must be, to adapt and improve apparatus and processes. To those, however, in charge of technical laboratories, all the information that can be given them in that direction is certain to be welcome.

To turn from the past to the future, amid much that is discouraging in the commercial aspect of chemistry, as in the commercial aspect of most else, there is no small reason for a hopeful view of the future in the evidences of vigorous life in our industries, and of sound method and good work on the part of those who conduct them; that our papers show and we may well hope that the officers and members of the various sections of our Society will show in the future the same zeal as in the past.

Yet there is no easy task before us. The progress of science in one sense makes our work easier no doubt, but on the other hand it demands of us continually increasing efforts to keep up to a standard constantly being raised to a higher level, and it is for us to show that England is not behind other countries in intelligence and aptitude for work. There is need for all our energies to do so. We need, no doubt, the technical education of which so much is talked nowadays, but it must be real and thorough to an extent that many who theorise about it seem to have no idea of; and, above all, we must know what we do want. I fear in many minds there lurks the idea that the technical education of workmen will release their employers from the necessity of thinking for themselves. The technical education of the fingers alone will never make a musician, and unless the heads of industrial concerns are willing to be so in deed as well as in name, that harmonious action on which success depends, is certainly impossible. Without a real scientific appreciation on the part of the head, it is impossible that the scientific training of subordinates can be of much avail.

Of novel ideas there seems no lack; it is rather sound application that we need. The patent law is supposed to give some guarantee of the novelty and practicability of the subjects of the patents granted, and the publications of the office show a ceaseless flow of invention, much of it really novel (though it does include preserving eggs with lime water, or lubricating the bearings of machinery with decomposed cabbages), yet of all this novelty, such as it is, no small portion is, as far as I can judge, never heard of again, beyond the stage of the blue pamphlet or the notices in our own or similar journals.

It is surely rather to that practical working out of ideas, whether new or old, of which we have been speaking, that we must look for progress, than to mere fertility of invention. Of that there may be the same abundance that there is of seeds in nature, which yet never can come to maturity without the needed seed bed and the farmer's fostering care.

VOTES OF THANKS.

Prof. Dewar moved that the hearty thanks of the Society be accorded to the President, Mr. David Howard, for his address. He added, with reference to the President's remarks upon the synthesis of conia, that during the last few weeks two French chemists had succeeded in synthesising the complex alkaloid of *Jaborandi*—viz., pilocarpine.

Colonel Gamble seconded the motion, which was carried unanimously.

The President replied, and then read the

REPORT OF THE SCRUTINEERS,

showing that the following had been duly elected Ordinary Members of the Council for the ensuing year:—

John Calderwood, F.R.S.E.
Eustace Carey.
R. Forbes Carpenter.
James Duncan.
Dr. John Evans, F.R.S.
S. H. Johnson.
John Pattinson.
B. S. Proctor.
F. J. Rowan.
Dr. Edw. Schunck, F.R.S.
T. W. Stuart.
Lewis T. Wright.

And that the nominations of Council for President, Treasurer, Foreign Secretary, and Vice-Presidents had been duly confirmed.

The following is therefore the composition of the Council for 1887—1888:

President.

Prof. James Dewar, F.R.S.

Vice-Presidents.

Prof. F. Clowes, D.Sc.
Sir J. Neilson Cuthbertson.
David Howard.
Dr. Ferdinand Hurter.
Ivan Levinstein.
E. K. Muspratt.
Dr. W. H. Perkin, F.R.S.
Sir H. E. Roscoe, M.P., F.R.S.
John Spiller.
Prof. W. A. Tilden, F.R.S.
John Williams.
Philip J. Worsley.

Members of Council.

John Calderwood, F.R.S.E.
Eustace Carey.
R. Forbes Carpenter.
James Duncan.
Dr. John Evans, F.R.S.
S. H. Johnson.
John Pattinson.
B. S. Proctor.
F. J. Rowan.
Dr. Edw. Shunck, F.R.S.
T. W. Stuart.
Lewis T. Wright.

Treasurer.
E. Rider Cook.

Foreign Secretary.
Ludwig Mond.

The President then proposed the re-appointment of Messrs. Theobald Bros. and Miall as Auditors for the ensuing year. The proposal was seconded by Mr. S. H. Johnson, and carried unanimously.

On the motion of Mr. Alexander M. Chance, seconded by Dr. D. B. Hewitt, a vote of thanks was accorded to the Treasurer and Officers of the Society, and the Chairman and Secretaries of Sections.

Mr. Ludwig Mond and Mr. Chas. Hunt replied.

On the motion of Mr. E. K. Muspratt, seconded by Mr. Ivan Levinstein, a hearty vote of thanks was given to the Council of Owens College for granting the use of the Chemical Lecture Theatre for the purposes of the meeting.

THE NEXT ANNUAL MEETING.

Mr. G. G. Henderson, as Secretary of the Glasgow and Scottish Section, then formally invited the Society to hold its Annual Meeting for 1888 in Glasgow.

On the motion of Prof. J. Campbell Brown, seconded by Prof. F. Clowes, it was resolved to accept with hearty thanks the invitation from the Glasgow Section.

VISIT TO THE ROYAL JUBILEE EXHIBITION.

In the afternoon, and indeed immediately after the conclusion of the proceedings in the morning, most of the members visited the Exhibition, in the Chemical Section of which they found one of the finest collections of the kind ever brought together. Nor was it to be wondered at that a high degree of interest should be felt by members of the Society of Chemical Industry in the Chemical Section of the Exhibition, for the arrangement and classification of the exhibits is such as to appeal at once both to their understanding and sympathy. The reason of this is not far to seek, for does not the committee of the Chemical Section of the Exhibition contain two of the Vice-Presidents (Mr. Levinstein the chairman, and Dr. Schunck), the Editor of the Journal, with the Secretary of the Manchester Section of the Society, and are not all its members members of the Society of Chemical Industry? It may be fairly claimed then that what success the Chemical Section of the Exhibition has achieved, is a triumph not only for the Committee of that section, but for the Society of Chemical Industry. The collection of the relics of great discoverers, and of their discoveries in the fields of chemical and physical science, made for the Exhibition Section by Mr. Watson Smith, created much interest. There were to be seen the battery, at least a part of it, with which Davy decomposed the alkalis, and his note-book, in which the record of the isolation of the alkaline metals could be read; the gases liquefied for the first time by Faraday, enclosed in sealed tubes, and his note-book opened at the place where the record of this remarkable discovery occurs; and, exceedingly interesting for Manchester and its neighbourhood, the specimen of the very first benzene isolated by Faraday, and the apparatus with which Joule determined the mechanical equivalent of heat. When it is added that there also was to be seen the manuscript of that page of Dalton's "Principles of Chemistry" which contains the table of his original atomic weights: the penny earthern inkpots and soda-water bottle he has converted into classic relics, and the original lamps which Davy constructed when feeling his way, with high-minded benevolence and scientific skill, towards a solution of the terrible problem which in those days forced itself to the front in men's minds—how to save from wholesale destruction those who laboured in the bowels of the earth to provide means of warmth, comfort, and light for their fellows—the question may be fairly asked—"Was not a sight of these things well worthy of a pilgrimage to Manchester?" Then, turning to more modern times, we have exemplified by specimens, dyed and printed fabrics, and picture representations, the researches which in their several directions have done much to keep the name of England in the front, as that of the land in which the first springs of chemical science, as applied to the chemical industries more especially, have arisen, whatever may be said of after developments and advances. It is only necessary to mention the names of Perkin, Griess, Schunck, Roscoe, Schorlemmer and Dale, to indicate sufficiently to chemists what mainly was to be seen in this interesting collection. It is a fact, and one worthy of some thought and consideration for the country, when the urgency of the special study of technical chemistry is in many cases so prematurely pushed, that the teaching of the applications of chemical science to the industries is demanded before the knowledge of the science itself is acquired, or anything approaching it,—that neither Perkin nor Griess were searching for colours or dyes when they obtained those results, which make them respectively the originators of the aniline- and the azo-colour industries. These chemists were both investigating the constitution of certain organic bodies, and were so far exploring the realms of abstract scientific truth, when with one and the same stroke there came with the practical refutation of their theories as first entertained, new revelations with a more tangible reward.

THE ANNUAL DINNER.

The annual dinner of the members of the Society of Chemical Industry was held in the Palm House of the Exhibition, and a little after six o'clock about 150 gentlemen sat down, Mr. David Howard, the retiring president, taking the chair. He was supported by the President-elect, Professor James Dewar, F.R.S.; Messrs. E. K. Muspratt, Ivan Levinstein, Dr. Hewitt, Ludwig Mond, Dr. Hurter, J. T. Brunner; Hy. Brunner, Prof. J. Campbell Brown, Mr. Alex. M. Chance, Mr. E. Carew, Mr. J. Brock, and Prof. F. Clowes.

The usual loyal toast, "The Queen," was given by the Chairman, in a speech in which he mentioned that those who had studied at the College of Chemistry in London in earlier days could appreciate how much the Queen, in conjunction with the late Prince Consort, had fostered chemical science, and that he was glad to think that the Prince of Wales also took a deep and practical interest in all scientific matters. The toast having been duly honoured, the next, "Prosperity to the Society of Chemical Industry," was then proposed by Mr. J. T. Brunner, who said he knew that the Society had done and was doing an immense amount of good. He was much pleased to know that his old friend, Prof. Dewar, was to be their president during the next year, and he was sure they could not have made a better choice.

Professor Dewar replied, and referring to his election, thanked the members for their recognition of the recondite side of chemical science. That Society had been founded, said he, not for the benefit of a class, but rather for the purpose of blending the classes of chemistry together; the manufacturing branch, on the one hand, and the abstract on the other. From the past history of the Society, its recognition of all classes in the disposal of its honours, and more on account of the unity which the members showed and the quality of the work produced, he was sure that its future was safe. He referred especially to the paper recently contributed to the Liverpool Section, by Dr. Hurter, which he considered to be a most admirable example of research and reasoning. He was not disposed to consider ominous the shifting—the apparent instability of science. They were merely moving on to higher things, getting nearer to the truth.

Dr. Hewitt then proposed the health of the President, whose name had been familiar to him since he was a boy. And now amidst advancing years, he knew that Mr. David Howard had a lineage and was connected with a firm foremost in making this country famous for the manufacture of fine chemicals.

Mr. Howard, replying, said that the Society was doing an amount of work which could only be appreciated by those who knew the difficulties which past generations of chemists had to contend with.

Mr. Tyrer next proposed "The Local Sections." He said that if that Society was anything it was democratic; but the elements of a thorough, sound and healthy Republicanism were there. He always had faith in its policy, and now, when, greatly through the concerted efforts of its sections, the Society and its Journal—with the life and prosperity of the latter of which that of the former was indissolubly connected and bound up—had undoubtedly become a powerful factor in the industry of the country, all should put their shoulders to the wheel and assist in the onward movement.

Mr. J. Carter Bell responded.

The health of the "Secretary and Editor" were finally proposed by the President.

Mr. C. G. Cresswell, replying, referred to the necessity for permanent quarters for the Society: and later on, Mr. Brunner expressed the hope that something definite would come out of it, if for no other reason than that they should have a room in which the library of the late Mr. Weldon could be placed.

Mr. Watson Smith joined Mr. Cresswell in returning thanks for the good wishes conveyed in the toast; and as he had assumed the direction of the musical arrangements and programme on that occasion, he would take that opportunity of expressing himself musically by playing Schubert's Impromptu in G.

During the evening a selection principally of part songs, by Mendelssohn and Schubert, from the well-known Orpheus series, was most effectively given by a choir of twelve men's voices.

THE EXCURSIONS, ETC.

On Thursday Morning a considerable number of members assembled at the Exchange Station for a trip to Wrexham, to visit the Wrexham Lager Beer Brewery. After an inspection of the brewery the party was entertained at an excellent lunch by the manager. After the repast a vote of thanks to the company was proposed by Mr. Howard, and carried unanimously. The party then returned to Chester, where conveyances were waiting to take them to Eaton Hall, the palace of the Duke of Westminster. After partaking of tea at Eccleston Ferry, the members returned in barges by the river Dee to Chester, and from thence they journeyed by rail to Manchester. Meanwhile smaller parties visited the works of Messrs. Crossley Bros. ("Otto" Gas Engine Factory); of Messrs. Beyer & Peacock, Engineers; Messrs. Kerr and Hoegger, Dyers; Messrs. Ermen and Roby, Bleachers; Messrs. Knowles & Co., Print Works; the Buxton Lime Works; Mr. J. Hollingworth; Messrs. I. Frankenburg, India-rubber Works; Messrs. Haworth & Co., Cotton Spinning; Messrs Chadwick & Taylor, Paper Works; Salford Sewage and Gas Works; and the *Guardian* newspaper office.

On Friday Morning another party was formed for visiting Chapel-en-le-Frith and Castleton, in Derbyshire. The members joining this excursion will not soon forget the satisfaction and pleasure it gave them, and the complete success of this, as well as the Chester excursion, were certainly in a large measure due to the indefatigable exertions of Mr. J. Carter Bell, the local secretary of the Manchester Section, as well as to the all-important circumstance of most propitious weather.

Another excursion was also organised, under the guidance of Mr. Wm. Thomson, to visit the extensive Printing, Bleaching, and Dye Works of Messrs. Ed. Potter & Co., at Dinting Vale, and thereafter the Paper Works of Messrs. Olive and Partington, at Glossop. Some twenty-five to thirty members availed themselves of these opportunities, and greatly enjoyed the combined excursion and visits.

In each and every case the members were received and treated with unvarying kindness by the proprietors of the works thrown open to them, and probably never before in the history of the Society has such a large variety of manufactures connected with the chemical industries been available for inspection at an annual meeting as on this occasion at Manchester.

London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: David Howard.

Committee:

Sir F. A. Abel.
H. E. Armstrong.
W. Lant Carpenter.
W. Crowder.
W. J. Dibdin.
C. Graham.
S. Hall.
C. C. Hutchinson.
R. Messel.
B. E. R. Newlands.
B. Redwood.
T. Royle.
John Spiller.
Wm. Thorp.
J. Williams.
C. R. Alder Wright.

Hon. Local Sec. and Treasurer: Thos. Tyrer, Garden Wharf, Church Road, Battersea, S.W.

The meetings of the London Section will be resumed on Monday, 7th November next.

The last meeting of the Session was held on Monday, 6th June, at the Chemical Society's Rooms, Burlington House, Piccadilly.

THE PRESIDENT IN THE CHAIR.

THE ALKALOIDS—THE PRESENT STATE OF KNOWLEDGE CONCERNING THEM, AND THE METHODS EMPLOYED IN THEIR INVESTIGATION.

BY HENRY E. ARMSTRONG,

Professor of Chemistry in the City and Guilds of London Institute, Central Institution.

Within recent years our knowledge of the alkaloids has increased to an extent and with a rapidity which is perfectly astonishing: a study of the circumstances to which this progress is due, and of the manner in which it has taken place, is in the highest degree instructive to the technologist.

The term "alkaloid," like so many of the generic terms in use in chemistry, is indefinable: literally it means alkali-like, but practically it is restricted to certain nitrogen compounds more or less directly derived from ammonia. It is hardly worth while, however, to discuss where the line shall be drawn; or to which among the almost innumerable alkali-like derivatives of ammonia the privilege shall be granted, or from which it shall be withheld, of appearing in the class of alkaloids: such a question is of importance only to those who may desire to put forward a claim to be the first to synthesise a natural alkaloid.

The vegeto-alkaloids have long been of importance on account of their medicinal and toxic properties. The amines—that group of alkaloids immediately derived from ammonia, with the discovery and investigation of which the names of Wurtz and Hofmann are so inseparably linked—have acquired the highest industrial importance as being the progenitors of a large proportion of modern dye-stuffs. And quite recently we have begun to recognise alkaloids among the products of putrefactive changes induced by micro-organisms, and to regard it as probable that the sufferings provoked in zymotic diseases may, at least to a large extent, be due to the toxic properties of alkaloids thus produced. From this last point of view alone the study of alkaloids is of enormous importance to the human race, our chance of combating the effects of zymotic disease being necessarily dependent on the recognition not merely of the immediate causes of such effects, but especially of the chemical attributes of the alkaloids concerned as well as of their physiological action. It is now many years since *the chemist* Louis Pasteur—to the eternal glory of our science be it said—made clear to all seeing eyes the important functions exercised by micro-organisms throughout the organic world; the study of these organisms necessarily passed into the hands of the morphologist, but the wheel of time is fast going round, and it is daily becoming more and more evident that the next great advance must be the outcome mainly of the chemist's labours. I recommend those who doubt this to study Brieger. Sooner or later also it will be for the chemist to suggest and prepare antidotes to the toxic alkaloids, and in concert with the physiologist to devise means of diverting the activity of disease-producing bacteria into harmless channels; it may even be suggested that the protection afforded by vaccination and by attenuated virus is perhaps in a measure due to alkaloids.[*] Indeed, it is obvious that there is an almost unbounded field awaiting exploitation by chemists, and that abundant opportunity is here afforded them of still further ministering to the public wants.

Having said so much by way of preface, let me also at the outset try to make clear the point of view from which I propose to consider the alkaloids. The various non-metallic elements in the states in which we know them are without exception compound in their nature—*i.e.*, their molecules consist of two or more atoms of the constituent stuffs: and we are as little able to infer the properties of these stuffs from observation of the properties of the elements as they present themselves to us as we are, for example, those of chlorine and sodium from those of common salt. In consequence of our disregard of molecular composition in the case of the elements, we are entirely misled by having become accustomed to speak of the elementary stuff symbolised by N and of its compound N_2 by the same name: hence it is that nitrogen is popularly regarded as the most inert among elements. Probably it is one of the most active: but so great is the stultifying effect exercised upon us in early youth by text-book statements that many will hesitate to accept this proposition. Nevertheless I advance it, and venture to maintain that we gain no idea whatsoever of the properties of nitrogen-stuff from a consideration of those of nitrogen gas or azote—to give it the older and more suggestive name—and that if we desire to determine its properties we must devote ourselves to the comparative study of the alkaloids. If the effects produced by alkaloids were effects produced by the molecules as wholes, we could not expect to deduce the properties of nitrogen-stuff from those of its compounds: but I believe we are justified in assuming that such is not the case, and that in every molecule there are one or more "points" from which the influence is exerted.

In formulating the nitrogen compounds, a difficulty arises owing to the fact that chemists still agree to differ regarding the valency of the element. The popular view at the present day is that nitrogen is a triad in ammonia and the amines, and a pentad in ammonium salts: some few among us—and I am one of these—regard the ammonium salts as "molecular compounds." This is not the occasion to discuss such a question: I refer to it to prevent misunderstanding.

The great majority of vegeto-alkaloids are derivatives of pyridine: before attempting to consider these I desire to direct attention to a group of alkaloids of natural origin, and to the *ptomaines* or alkaloids resulting from the putrefactive change of animal matter.

Trimethylamine alkaloids.—Under this name may conveniently be included four closely related compounds, the names, formulæ and proximate constituents of which are as follow:—

NAME.	FORMULA.	PROXIMATE CONSTITUENTS.	
Neurine	$NMe_3[HO.CH.CH_2]$	Trimethylamine	+ vinyl alcohol
Choline	$NMe_3[HO.CH_2.CH_2.OH]$.	,,	+ glycol
Muscarine	$NMe_3[HO.CH_2.CH(OH)_2]$	,,	+ hydroxyacetaldehydrol
Betaine	$NMe_3[HO.CH_2.COOH]$ ..	,,	+ hydroxyacetic acid

Choline is a constituent of brain matter, but has also been obtained from a variety of other sources. It may be prepared synthetically by digesting an aqueous solution of trimethylamine with ethylene oxide. Neurine has also been separated from brain matter, but it may be prepared from choline, and it is a question whether it is a proximate product of hydrolysis or whether it is not formed from choline during the process of separation. Muscarine occurs, together with choline, in the fly agaric (*Agaricus muscarius*), and may be produced by oxidising choline by means of nitric acid. Betaine was originally separated from the juice of the beet (*Beta vulgaris*), but has since been found in other plants; it may be prepared synthetically from trimethylamine and chloracetic acid, also from glycine, and it is obtained on oxidising choline—with which it is associated in cotton seed, for example—with chromic mixture. It will be obvious, therefore, that a close genetic connexion exists between the four compounds, and this being the case, the differences in their toxic qualities are especially noteworthy. Muscarine, neurine and choline all have a similar physiological action: muscarine, however, is a virulent poison, and so also is neurine, but I believe to a less extent, and choline is a much less active substance than even neurine; I am not aware that betaine is credited with any poisonous qualities. Now, if physiological activity be in any way proportional to alterability in a chemical sense—to the tendency to be acted upon by, or to enter into combination with, or to interact with, other substances, then muscarine should certainly be the most active of the four compounds in question, as it is an aldehydrol (aldehyde hydrate), the reactivity of aldehydes exceeding that of all known compounds. For similar reasons it is to be expected that neurine would take the second place, and choline the third, glycol, which may be regarded as a proximate constituent of choline, being undoubtedly less prone to undergo change than would be (the hypothetical) vinylic alcohol, which it may be assumed is

---

[*] Since writing this I have received the Proceedings of the Royal Society, No. 254, which contains a most suggestive "Note on Protection of Anthrax," by Dr. L. C. Wooldridge. Dr. Wooldridge has grown the anthrax bacillus in a culture fluid consisting of a solution of a proteid body discovered by himself, obtained from the testis and from the thymus gland; and he finds that if a small quantity of the filtered culture fluid be injected into the circulation of a rabbit, the animal will not take anthrax. The injection of the fluid in which no anthrax bacillus has grown is without effect, and if the bacillus grown in the fluid be inoculated it either kills or it has no effect. If other albuminous fluids—*e.g.*, blood serum, be used as a culture medium, and the filtered culture fluid be injected, it exerts no protection. Hence, as Dr. Wooldridge says, it may fairly be concluded that the growth of the anthrax bacillus in the special culture fluid used gives rise to a substance which, when injected into the organism, protects against an immediate and subsequent attacks of anthrax. In this note apparently we have the germ of a discovery the practical importance of which it is impossible to exaggerate.

contained in neurine. The very slight difference in composition between choline and either neurine or muscarine is also to be remarked, the withdrawal of the elements of a molecule of water sufficing to convert choline into neurine, while its conversion into muscarine involves but the displacement of a single hydrogen atom by the hydroxyl group. Seeing that many micro-organisms act most powerfully in inducing oxidation, it is obvious that no great margin of safety can be counted on, as choline—or its potential elements exists widely distributed throughout the animal organism.

Ptomaines. Within recent years the attention of toxicologists has been directed—especially by the Italian chemists—to the presence in putrid animal matter of poisonous basic substances, more or less resembling certain natural alkaloids, and which become separated in the course of the treatment usually adopted in the toxicological examination of human remains. The discovery is obviously one of the first importance to the medical jurist, and naturally attracted much attention. Selmi, whose systematic study of the subject entitles him to be regarded as the pioneer in this field of investigation, although he was by no means the first to recognise their existence, has designated alkaloids which result from the putrefaction of albuminous matters as *Ptomaines* (πτωμα—a corpse). The recognition of the production of *ptomaines* during putrefaction was based, in the first instance, on qualitative chemical and physiological tests, and not on their separation in the pure state. Nencki appears to have been the first to isolate a ptomaine, but did himself the injustice of publishing his experiments in a semi-private pamphlet. It is to Brieger, however, that we are indebted for the exact knowledge which we now possess on the subject. His labours, carried on uninterruptedly since 1882-83, have resulted in the discovery of numerous non-poisonous, as well as poisonous, alkaloids, and are of the highest importance, not only to the physiologist and medical jurist, but also to the chemist, on account of the light which they throw on the composition of animal albuminous matters, and on the course of putrefactive changes.

Brieger's researches not only prove that a variety of alkaloids result from the poisonous decay of animal matters, but they establish the fact that ptomaines are formed during the earlier stages of decay, and that they are of a non-benzenoid character; as putrefaction continues, they gradually disappear, and give place to well-known benzenoid compounds—phenol, cresol, hydroxy-acids, indole, etc. In the first part of his collected researches,* Brieger describes the ptomaines produced—(*a*) from putrid horseflesh, beef and human muscular tissue; (*b*) from putrid fish; (*c*) from putrid cheese; (*d*) from putrid glue; and (*e*) from putrid yeast. In every case large quantities of material were taken, and the methods employed in separating the ptomaines were such that, as far as possible, their decomposition was prevented. The same substances were separated from putrid horseflesh, beef and human flesh, but horseflesh gave the largest amounts, and therefore was chiefly used. The products from animal flesh were neurine—the intensely poisonous nature of which has already been mentioned, and a non-poisonous diamine ($C_5H_{14}N_2$), the hydrochloride of which crystallises in well-defined long needles resembling urea crystals. This was named *neuridine*, as it appears to bear some relation to neurine, being resolved into a mixture of dimethylamine and trimethylamine when boiled with caustic soda solution. Putrid fish gave a toxic base of the composition of ethylene diamine ($C_2H_8N_2$) but isomeric therewith; muscarine; a second novel base of the formula $C_7H_{17}NO_2$, which Brieger names gadinine from *Gadus callarias*, the fish used: it appears to be non-poisonous: and, lastly, triethylamine, which had not previously been known to be derivable from any such source. From soft cheese allowed to putrefy for six weeks, he obtained neuridine and trimethylamine. Glue, from which Nencki obtained a collidine by allowing it to putrefy in contact with ox pancreas, gave neuridine in larger quantities than any other material examined, together with dimethylamine and traces of a substance resembling muscarine in physiological properties. Putrid yeast gave only dimethylamine.

In the second part of his collected researches, Brieger describes the results of his examination of the basic products of the gradual putrefaction of human remains, especially the internal organs—viz., the lungs, heart, liver, spleen, stomach and intestines; and he particularly directs attention to the progressive character of the changes. Material taken from corpses which had lain 24—48 hours in a cool cellar gave choline in small quantity, but no other ptomaine. After a slightly longer interval, neuridine was the chief product, only traces of choline being found, and, in some instances, trimethylamine. Putrefaction being allowed to continue for a considerably longer period, the choline was found to have entirely disappeared, three new physiologically indifferent bases being now separable—viz.:

Cadaverine	$C_5H_{16}N_2$
Putrescine	$C_4H_{12}N_2$
Saprine	$C_5H_{16}N_2$

At least two toxic alkaloids are also formed in the later stages of putrefaction, but in such small quantity that Brieger did not succeed in isolating sufficient for analysis. It is remarkable, as Brieger points out, that the bases which he was successful in isolating are all diamines;† no previous investigation of albuminous substances entitles us to anticipate the formation of such compounds, or affords any clue to their origin. In the experiments under discussion, the air had free access; in the third monograph, Brieger briefly describes experiments made on a very large scale in which human remains, horseflesh and fish of different kinds were allowed to putrefy during the months of October to January in a stable loft at a temperature ranging from 5° to 9° C. in such a way that the access of air was almost prevented: it is a matter of interest that although under these conditions cadaverine and putrescine were formed in considerable quantity, no highly-poisonous ptomaines could be discovered. It would seem, therefore, that their formation takes place only when a certain amount of atmospheric oxygen has access.

The most important results obtained by Brieger, however, are undoubtedly those relating to the putrefactive action of pure cultivations of certain pathogenic bacteria. The *staphylococcus pyogenes aureus* and *streptococcus pyogenes*, described by Rosenbach, gave only negative results, no toxic alkaloid being formed by them; but by means of the *typhus bacillus* of Koch and Eberth, a toxic alkaloid was obtained of the formula $C_7H_{17}NO_2$ but unfortunately in very small quantity, its formation being apparently dependent on certain very

† Brieger's cadaverine has been shown by Ladenburg to be identical with the pentamethylene diamine

$$(NH_2.CH_2.CH_2.CH_2.CH_2.CH_2.NH_2)$$

obtained on reduction of trimethylene cyanide

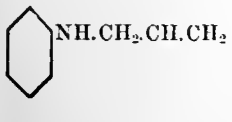
$$(NC.CH_2.CH_2.CH_2.CN).$$

special conditions being fulfilled. Employing a microbe which has been recognised as the primary cause of traumatic tetanus in man to cause the putrefaction of beef, Brieger, however, has succeeded in isolating an alkaloid, which he has named tetanine, of the formula $C_{13}H_{30}N_2O_4$; this produces in animals all the symptoms characteristic of human tetanus. Bocklisch, at Brieger's suggestion, has recently studied the products of putrefaction obtained by means of Finkler and Priors's comma bacillus, but without discovering any specific toxic alkaloid. Enough has now been said to make clear the enormous importance of Brieger's researches; they certainly may be described as "epoch-making."

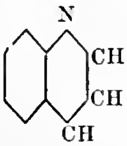
Pyridine Alkaloids.

Pyridine was discovered by Anderson in 1857, in the course of his classical researches on bone-oil: quinoline was discovered by Gerhardt in 1842. The nature of these compounds long remained undetermined, comparatively little attention being paid to them, probably in consequence of the difficulty of obtaining the pure substances in quantity. Gradually, however, their importance as progenitors of the vegeto-alkaloids became recognised. The discovery by Skraup of a most elegant synthetic method of preparing quinoline, available also for the preparation of a variety of quinoline derivatives, followed as it was very rapidly by the discovery of other simple methods of preparing both pyridine and quinoline derivatives, not only rendered their systematic study possible, but highly fashionable among chemists, many of whom doubtless were not uninfluenced by the hope that their researches might furnish results of immediate pecuniary value; the result is that the special literature of the subject is already almost overpowering, the rate of progress having been simply marvellous.

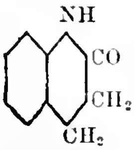
The suggestion that pyridine closely resembles benzene—that in fact it is benzene in which N takes the place of CH, and that quinoline is related to naphthalene in the same way that pyridine is to benzene, is more often than not attributed to Körner, but is sometimes ascribed to Dewar, to whom I believe it to be due: the now conventional formula of pyridine having been first published by him in a paper read at the Royal Society of Edinburgh on the 6th of June, 1870 (*R. S. Ed. Trans.* 26, 189). The method of oxidation by permanganate, which has been of such signal service in the investigation of pyridine derivatives, was also first described in this paper. The truth of Dewar's surmise was experimentally verified in 1879, when Koenigs showed that allylaniline is converted into quinoline by passing it over red-hot lead oxide, and Baeyer succeeded in converting hydrocarbostyril (orthamidophenylpropionic anhydride) into quinoline; the nature of the proof of the constitution of what is conventionally termed the "pyridine ring," which these syntheses afford will be obvious on reference to the following formulæ :—



Allylaniline.

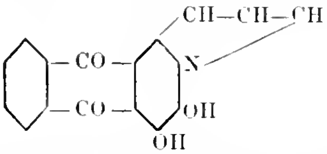


Quinoline.



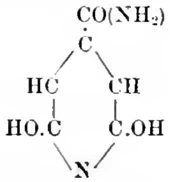
Hydrocarbostyril.

Skraup's invaluable synthetic method of preparing quinoline—the discovery of which may be said to be the critical feature in the history of our knowledge of the vegeto-alkaloids—affords one of the most instructive instances on record of the fact that every experiment, however unpractical it may seem at the time, has its value; it also illustrates the intimate connection of theory with practice, and should for ever silence the so-called practical man who knows nothing of, and cares less for, theory. Prudhomme, in 1877, stated that if β-nitroalizarin (alizarin orange) be heated with glycerol and sulphuric acid, a mixture of two colouring matters is produced, the one giving a violet with alumina mordants and a blue with iron mordants, the other giving browns. Most people would characterise such a mixture as a "dirty mess," and it is difficult to understand how the experiment came to be made, but made it was, very fortunately. H. Brunck, a member of the Badische Anilin- and Soda-fabrik, took up the study of the subject, and succeeded not only in determining the conditions under which the blue dye was formed, but in producing it on a manufacturing scale; and it is now well known as a very valuable dyestuff under the name alizarin blue. The scientific investigation of alizarin blue was undertaken by Professor Graebe with material furnished to him by Brunck, and ultimately he came to the conclusion that it has the composition indicated by the formula—



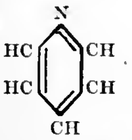
being in fact a derivative of anthraquinoline—*i.e.*, a compound bearing the same relation to anthracene that quinoline bears to benzene. Now it is remarkable that Graebe's paper immediately follows in *Liebig's Annalen* a paper by Skraup on the "Constitution of Cinchonine;" whether Skraup was thus led to take particular note of Graebe's work I do not know, but at all events it suggested to him that nitrobenzene might be converted in the same way—*i.e.*, by heating it with glycerol and sulphuric acid, into quinoline, and he was thereby led to discover his method of preparing quinoline.

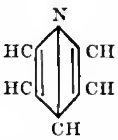
Among the very numerous syntheses of pyridine derivatives, there is one to which attention should be specially directed, on account of the conditions under which it takes place. I refer to the action of aqueous ammonia on the acetyl derivative of ethyl citrate, which interact at ordinary temperatures to produce *citrazinamide* (Ruhemann, *Chem. Soc. Trans.*, 1887, 403), a compound represented by the following formula * :—



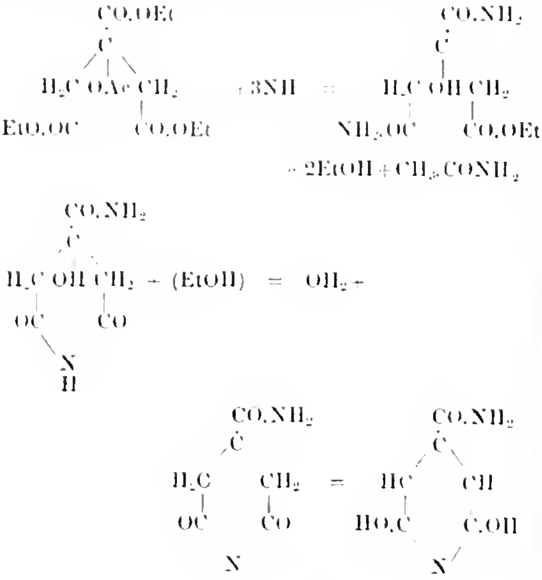
---

* Just as in the case of benzene, much discussion has taken place regarding the possible alternative formulæ of pyridine—viz :—



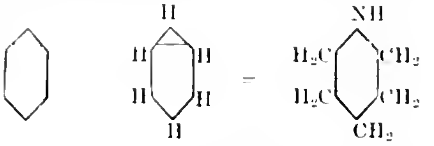


—Ruhemann contending that the formation of a pyridine derivative in the manner above described affords conclusive evidence in favour of the second formula. Like all such questions, this is one of considerable importance, but it would be out of place to discuss it here; I refer to it merely in order to point out that, in my opinion, neither can be accepted. I would, in fact, employ a formula corresponding to that which I have elsewhere contended should be assigned to benzene (*Chem. Soc. Trans.* 1887, 264). For all practical purposes it is sufficient, It is pyridine in which two hydrogen atoms are displaced by OH, and one by $CO(NH_2)$. Its formation may be symbolically represented, thus :—



It remains now to consider the chief evidence which recent investigations afford of the nature of the vegeto-alkaloids.

Piperidine ($C_5H_{11}N$).—This alkaloid was shown by Anderson in 1850 to be produced together with piperic acid, $C_{12}H_{10}O_4$, on hydrolysing piperine—a constituent of pepper. The nature of piperidine was not finally determined until 1869, when Koenigs succeeded in converting it into pyridine by heating it with sulphuric acid at 300°. The change involves the mere withdrawal of six atoms of hydrogen. Taking into account the fact that piperidine is a secondary amine, pyridine being a tertiary amine, the relation between the two is satisfactorily denoted by the formulæ :—



Pyridine. Piperidine.

Complete confirmation of the formulæ here given is afforded by the synthesis of piperidine from pentamethylenediamine effected by Ladenburg in 1886. This diamine is prepared by the action of sodium on a boiling alcoholic solution of trimethylene cyanide :—

$$NC.CH_2.CH_2.CH_2.CN + 8H = H_2N.CH_2.CH_2.CH_2.CH_2.CH_2.NH_2.$$

A certain quantity undergoes conversion into piperidine even during this process, and complete conversion is effected by submitting the hydrochloride of the diamine to dry distillation.

Piperic acid has been shown by the researches of Fittig and his pupils to be a derivative of protocatechuic or 1 : 2 : 4 dihydroxybenzoic acid of the formula :—

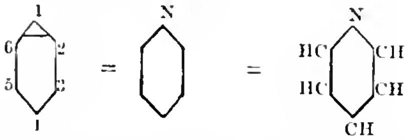
$$CH_2 \left\{ \begin{matrix} O \\ O \end{matrix} \right\} C_6H_3.CH.CH.CH.CH.COOH.$$

Piperine is a stimulant stomachic (Lauder Brunton's "Pharmacology"). Pyridine is said to diminish the reflex activity of the spiral cord and respiratory centre ; from Dewar and McKendrick's experiments it would appear to have a slight exciting action on the nerve centres, and those of Lee show that this is usually followed by paralysis. Piperidine appears to act chiefly as a local anæsthetic, paralysing the peripheral terminations of sensory nerves. It depresses the action of the heart and respiration.

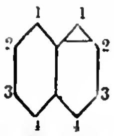
Coniine.—Coniine is the poisonous principle of hemlock (*conium maculatum*), from which it was separated by Giesecke in 1827. It was supposed to have the composition $C_8H_{15}N$ until 1881, when Hofmann showed that its formula is $C_8H_{17}N$; later on, in 1884, he brought forward a number of observations which practically all but solved the problem of its constitution. Desiring to convert coniine into octylamine, Hofmann distilled the hydrochloride over heated zinc dust, but obtained instead a base of the formula $C_8H_{11}N = C_8H_{17}N - 6H$, which he named *conyrine*, and bearing therefore the same relation to coniine that pyridine bears to piperidine. Conyrine was reconverted into coniine by heating it with hydriodic acid. On oxidising conyrine Hofmann obtained the pyridinecarboxylic acid known as picolinic acid, which Skraup and Coblenzl had a short time before proved to contain the carboxyl group in the ortho-position relatively to the nitrogen. Conyrine therefore is N : 2 propyl- or isopropyl-pyridine, and coniine is the hexhydro-derivative of this compound. The next chapter in the history of coniine relates to its synthesis. It is well known from Hofmann's researches that methylaniline is converted into the isomeric toluidine at a high temperature : Ladenburg therefore endeavoured to prepare propyl and isopropyl-pyridine by heating pyridine with propyl-and isopropyl-iodides, but succeeded in obtaining only the isopropyl compound ; the hydro-derivative prepared from this very closely resembled coniine in physiological action, but was slightly different in other respects : it therefore appeared probable that coniine was the propyl compound. To prepare orthopropylpyridine, pure N : 2 methyl-pyridine (α-picoline) was prepared from bone oil ; this was converted into

---

as in the case of benzene, to use a simple hexagon to represent pyridine ; and I here venture to suggest that in order to simplify printing, instead of writing N at one of the angles a line should be drawn across, thus :—



It is desirable to number the positions exactly as in the case of benzene, the nitrogen position being marked 1 : the usual continental custom of disregarding the nitrogen in numbering, and of marking the remaining positions 1, 2, 3, 4, 5, is unnecessarily misleading. The positions of the radicles are best indicated relatively to the nitrogen, assuming this to be in position 1. Thus the pyridinecarboxylic acid in which the COOH is contiguous to the N atom may be represented as the N : 2 acid. Applying this same principle to quinoline derivatives, the positions may be numbered alike in the two hexagons, thus :—



The position of radicles in the N ring are represented precisely as in the case of pyridine derivatives : cinchonic acid, for example, is N : 4 quinolinecarboxylic acid. Positions in the N-free ring are indicated by writing the figures in front of the N symbol—thus quinanisol, the methoxyquinoline derived from quinine, is 3 : N methoxyquinoline. Quininic acid, the oxidation product of quinine, is 3 ; N ; 2 methoxyquinolinecarboxylic acid.

allylpyridine by heating it with paraldehyde; and finally, N : 2 propyl-piperidine was obtained by hydrogenising the allylpyridine so prepared. The product differed from natural coniine in optical behaviour, being without action on polarised light; and its hydrochloride fused at 204°, that prepared from natural coniine fusing at 218°; in all other respects the two substances were indistinguishable. Attempts were therefore made to obtain from the synthetic product an optically active modification by the method successfully adopted with a similar object by previous workers—viz., that of selective destruction by means of a mould allowed to grow in a solution of the alkaloid; but the attempt was unsuccessful. The alkaloid was therefore converted into the acid dextro-tartrate: on adding to the very concentrated solution a few fragments of the acid dextro-tartrate from natural coniine, crystallisation took place, and from the crystals so prepared, after due purification, an optically active product was separated having the rotatory power $\alpha_D = 13·87$, that of natural coniine being $\alpha_D = 13·79$; the hydrochloride from this synthetic alkaloid had the same fusing point as that from natural coniine. Inasmuch as α-picoline may be prepared without resorting to any natural source, Ladenburg therefore has performed the feat of preparing coniine by purely artificial processes: there is no more brilliant achievement recorded in the annals of chemical science, and it would be difficult to select a research which more clearly illustrates the perfection of our modern chemical methods; the inter-dependence of researches undertaken at various times and with the most diverse objects; the necessity for the continued exercise of the severest logic; the multiplicity of processes with which the chemist must be intimately acquainted; and the demands made not only on his manipulative skill, but also on his patience and persevering fortitude under the trial of repeated failure and rebuff.

The physiological action of piperidine has already been mentioned. Dr. Lauder Brunton tells me that an interesting relation appears to exist between that of piperidine and coniine, inasmuch as the former acts chiefly by paralysing the peripheral terminations of sensory nerves, while coniine paralyses the corresponding parts of motor nerves.

Atropine.—This alkaloid, which is a powerful poison, is extracted from the leaves of the deadly nightshade, *Atropa Belladonna*: its most noteworthy physiological action is that which it exercises on the eye, causing dilation of the pupil. Atropine is easily hydrolysed, thus—

$$\underset{\text{Atropine.}}{C_{17}H_{23}NO_3} + OH_2 = \underset{\text{Tropic acid.}}{C_9H_{10}O_3} + \underset{\text{Tropine.}}{C_8H_{15}NO}$$

Tropic acid is the *phenylhydroxypropionic acid* of the formula

$$CH_2(OH).CH(C_6H_5).COOH.$$

The precise relation of atropine to its products of hydrolysis is not known: it is probably an ethereal salt. Ladenburg has shown, however, that atropine may easily be reproduced by merely digesting the tropic salt of tropine with dilute muriatic acid on the water bath; and by substituting other acids—such as benzoic, the hydroxy-benzoic, mandelic (phenylhydroxyacetic) and cinammic—for tropic acid he has prepared a number of compounds allied to atropine, which he proposes to term *tropeines*. It is especially noteworthy that *homatropine*, $C_{16}H_{21}NO_3$, the lower homologue of atropine prepared from mandelic acid, acts almost as powerfully as atropine as a mydriatic, but the effect which it produces is less persistent, lasting from 12 to 24 hours instead of eight days; it is also a far less powerful poison than atropine: hence in placing homatropine at the disposal of the eye-surgeon, synthetic chemistry has provided a material which in many cases is to be preferred to the natural alkaloid. This example is a good illustration of the important nature of the service which chemistry will undoubtedly afford to medicine, and therefore to mankind at large, as our inquiries are pushed forward in the particular field considered in this paper. Cinnamyl-tropeine, $C_{17}H_{21}NO_2$, has a very slight, if any, mydriatic action, but is a powerful poison: this is an interesting fact on account of the slight difference in composition which obtains between cinnamyl-tropeine and atropine.

The constitution of tropine cannot be regarded as finally determined: Ladenburg, however, is of opinion that his experiments, to which reference will now be made, prove it to be a tetrahydropyridine derivative of the formula—

$$C_5H_7(C_2H_4.OH)N.CH_3.$$

By the action of acids, and especially of concentrated sulphuric acid, tropine is readily deprived of the elements of a molecule of water and converted into tropidine, $C_8H_{13}N$; the connection of tropine with pyridine is established by the observation that on heating tropidine bromhydride with five molecular proportions of bromine at 165°, dibromopyridine and ethylene bromide are obtained.

Tropine has the properties of a tertiary base; that the nitrogen atom carries a methyl group is proved by the observation that tropidine methyl-iodide—prepared from tropidine and methyl iodide—yields *dimethylamine* when decomposed by alkali, thus:

$$C_8H_{13}N.CH_3I + KOH \quad NH(CH_3)_2 \quad C_7H_{10}O + KI.$$

If tropine be heated with hydriodic acid and phosphorus, it is converted into tropine iodide, $C_8H_{15}NI_2$; this compound exchanges only one of its iodine atoms for chlorine when it is digested with silver chloride, although both are displaced when it is boiled with silver nitrate solution, in this respect resembling the iodide $C_5H_{13}NI_2$ obtained from choline, and the bromide formed by combination of trimethylamine and ethylene bromide.

By digesting tropine-iodide with zinc dust and dilute muriatic acid, hydrotropidine, $C_8H_{15}N$, is produced, and by distilling hydrotropidine hydrochloride in a current of hydrogen chloride norhydrotropidine, $C_7H_{13}N$, is obtained; norhydrotropidine is a secondary base, and its production in this manner affords further evidence that the nitrogen atom in tropine is associated with a methyl group. On distilling norhydrotropidine hydrochloride with zinc dust, a decomposition is effected similar to that which takes place in the case of coniine, a pyridine base of the formula $C_7H_9N = C_7H_{13}N - 4H$ being produced. This base is α or N : 2 ethylpyridine, and hence it may be inferred that the side chain $(C_2H_4.OH)$, which probably is present in tropine, is in the ortho-position relatively to the N-atom.

Hyoscyamine and *Hyoscine.*—These alkaloids are isomeric with atropine, and like it in physiological action. Hyoscyamine, which was originally obtained from *Hyoscyamus niger*, occurs together with atropine in Atropa Belladonna; *Datura Stramonium* also contains the same two alkaloids, hyoscyamine, however, being the chief constituent, whereas Atropa Belladonna yields a larger proportion of atropine (Ladenburg, *Berichte*, 1880, 380, 909). Hyoscine occurs together with hyoscyamine in Hyoscyamus (*Ibid.* 1880, 1549; 1881, 1870; 1884, 151). *Duboisine* from the Australian plant *Duboisia Myoporoides* was found by Ladenburg to be impure hyoscyamine (*Ibid.* 1880, 257); recently he has examined another sample and has found this to consist of hyoscine (*Ibid.* 1887, 1661).

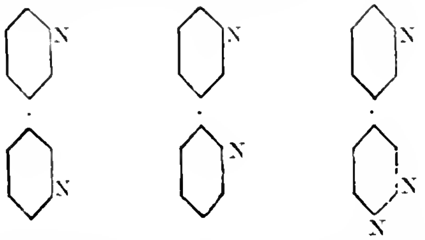
Hyoscyamine gives the same products of hydrolysis as atropine, and Ladenburg has prepared atropine from the products of the hydrolysis of hyoscyamine, thus converting the one alkaloid into the other: the relation between the two alkaloids must therefore be of an intimate character. Hyoscine on hydrolysis gives tropic acid, together with an isomer of tropine —pseudotropine.

Cocaine, which has recently acquired such notoriety in surgical practice, also belongs to the class of mydriatic alkaloids; on hydrolysis it yields benzoic acid, methyl alcohol and ecgonine (Lossen):

$$C_{17}H_{21}NO_4 + 2H_2O = C_7H_6O_2 + CH_4O + C_9H_{15}NO_3$$

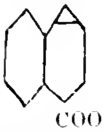
Cocaine has been prepared by methylating *benzoyl-ecgonine*, which accompanies cocaine in coca leaves. Ecgonine exhibits phenolic properties: its constitution, however, remains to be determined.

Nicotine: $C_{10}N_2H_{14}$.—It is desirable to briefly refer to this alkaloid, as it appears to belong to a distinct and unusual type. Mild oxidising agents deprive nicotine of four atoms of hydrogen, but more powerful agents convert it into nicotinic acid—the pyridinecarboxylic acid in which the COOH group and the N atom are relatively in the meta-position. It would therefore appear probable that nicotine is the hexhydro-derivative of a dipyridyl of which there are but three modifications capable of yielding nicotinic acid on oxidation—viz.:



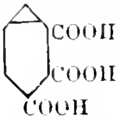
That represented by the first formula, would yield only nicotinic acid on oxidation; that represented by the second might also furnish picolinic acid, which, however, on account of its instability, might well escape detection; and that represented by the third formula may be expected to yield the N : 4 carboxy-acid, which is very stable and not likely to be overlooked.* The probability that the first or second represents the dipyridyl from which nicotine is derived is therefore considerable. By reducing by means of tin and muriatic acid the dipyridyl obtained by the action of sodium on pyridine, Weidel and Russo have prepared an isonicotine, the poisonous properties of which are much less marked than those of nicotine; this is probably a derivative of para-dipyridyl, as the dipyridyl is converted into the N : 4 carboxy-acid on oxidation. In a similar manner, Skraup and Vortmann have prepared a second isomer of nicotine—*nicotidine*—from the dipyridyl represented by the first of the above formulæ; this appears to be a powerful poison. We have therefore a certain amount of negative evidence in favour of the second of the above formulæ, provided it be assumed that the dipyridyl from which nicotine is probably derived would be directly converted into nicotine by the treatment adopted; but this does not follow as a matter of course.

Cinchona alkaloids.—Of the numerous alkaloids derived from the *cinchonas*, cinchonine and quinine have hitherto chiefly engaged the attention of chemists, and notwithstanding the persistent attack to which these two have been subjected, our knowledge of their constitution is still far from complete. Both are quinoline derivatives. In the case of cinchonine, $C_{19}H_{22}N_2O$, this is proved by its behaviour on oxidation with chromic liquor, whereby it is converted into *cinchonic acid*, the quinoline carboxylic acid of the formula

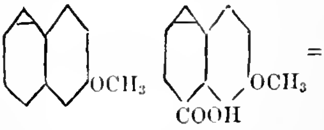


$= C_9NH_6.COOH$

Quinine, $C_{20}H_{24}N_2O_2$, in like manner, yields *quininic* acid, $C_{11}H_9NO_3$, when similarly treated. Both acids give the same tricarbopyridinic acid on oxidation by permanganate, viz.:—



and it is therefore evident that the difference in composition of cinchonic and quininic acids is due to the presence of a radicle in the "benzene ring" of quinoline: this radicle is proved to be methoxyl, CH_3O, by the formation from quininic acid by the action of muriatic acid of methyl chloride and xanthoquininic acid, $C_{10}H_7NO_3$, and by the resolution of this latter acid into carbon dioxide and hydroxy-quinoline. Quininic acid is split up in like manner on heating into carbon dioxide and methoxy-quinoline or quinanisoil. The hydroxy- and methoxy-quinoline obtained in this way are respectively identical with the compounds synthetically prepared by Skraup's method from paramidophenol, $C_6H_4(NH_2).OH$, and paramidanisoil, $C_6H_4(NH_2)OCH_3$, and hence the constitution of quininic acid is fully determined.



$= C_9N(OCH_3)H_5.COOH$

Quinanisoil. Quininic Acid.

Deducting C_9NH_6 from the formula of cinchonine, and $C_{10}NH_8O$ from the formula of quinine, the difference, $C_{10}NH_{16}O$, represents the composition of the group which is associated with quinoline in cinchonine, and with 3 : N-methoxyquinoline or quinanisoil in quinine; and it is not improbable that this group is associated with the quinoline by means of one of its carbon atoms, and occupies the para-position relatively to the nitrogen atom. We have no reason to suppose that the group $C_{10}NH_{16}O$ differs in structure in the two alkaloids.

Besides cinchonic or quininic acid, a complex mixture of products is obtained when either cinchonine or quinine is oxidised. Skraup, to whom especially we are indebted for our knowledge of the facts on which the determination of the constitution of the cinchonine alkaloids is based, has stated that he has succeeded in unravelling these, and in his preliminary notice (*Monatshefte*, 1886, 517) he mentions having isolated, among other compounds, a base of the composition $C_9H_{17}NO_2$, which, on distillation with zinc dust, yields ethylpyridine identical with that previously obtained by various observers from cinchonine, and there can be little doubt therefore that the group

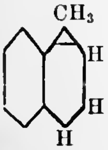
---

* Weidel has obtained this acid in very small quantity, and thinks that nicotine may perhaps be a mixture of isomeric substances.

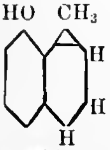
$C_{10}NH_{16}O$ in cinconchonine and quinine is derived from ethylpyridine, and that both alkaloids contain a pyridine besides the quinoline ring.

It has been assumed above that the quinoline ring is present in the unreduced form: but from the amount of hydrogen contained in cinchonine and quinine there can be no doubt, when all the facts are taken into account, that either the quinoline or the pyridine ring must be reduced to the tetrahydride. Skraup, by a most ingenious train of reasoning, has shown that it is more probable that the pyridine ring is reduced. The argument may be briefly stated as follows:—Quinanisoil is easily converted by digestion with tin and hydrochloric acid into a tetrahydride, which has been named *thalline* on account of the green colour which is produced in its solutions by oxidising agents but not by chlorine and ammonia; thalline is a strong antipyretic; it does not fluoresce. Quinanisoil itself is a weak antipyretic; it fluoresces, and moreover it resembles quinine in its behaviour with chlorine water and ammonia. The resemblance which quinanisoil bears to quinine, therefore, is destroyed when, by reduction, it is converted into the tetrahydride. On the other hand, quinine itself may be reduced, and furnishes a product which behaves exactly like thalline with oxidising agents; this behaviour affords a further indication of the presence in quinine of an unreduced quinoline ring.

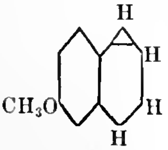
Quinine Substitutes.—The discovery of synthetic methods of preparing quinoline and its derivatives soon gave an impulse to the investigation of the physiological action of various quinoline derivatives, and attention appears to have been specially directed to the tetrahydro-derivatives by Dewar and M'Kendrick's investigation (*R. Soc. Proceedings*, 1874, 290), in which it was determind that the physiological activity was greater in those bases which contained the larger proportion of hydrogen. In 1881, Otto Fischer prepared from 1 : N-hydroxyquinoline the tetrahydro-derivative, and displaced the H of the NH group by CH_3. The compound thus produced was found to be a powerful antipyretic, and under the name of *kairine* has acquired some popularity in medicinal practice. Subsequently methylated tetrahydroquinoline was prepared by L. Hofman and Koenigs, and was also proposed as an antipyretic, being known as *Kairoline.* Thalline, the isomer of kairine, prepared by Skraup from quinanisoil, to which reference has been made above, was brought forward at a later period as an antipyretic. The formulæ of the three compounds are as follows:—



Kairoline.



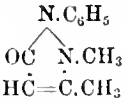
Kairine.



Thalline.

Many noteworthy observations indicating the connection between constitution and physiological activity have been made in the course of the inquiries which culminated in the introduction of these various substances as medicinal agents. Thus Filehne, who studied the physiological action of 1: N-hydroxyquinoline and its derivatives at Otto Fischer's instigation, found that this base and the methoxyquinoline formed from it possessed poisonous properties; their tetrahydrides manifested a certain resemblance to quinine, but produced objectionable subsidiary effects; on displacing in these latter the H of the NH group—to which, on chemical grounds, there was reason to attribute their activity—by methyl or ethyl, powerful antipyretics were obtained which were not subject to the objections which could be made against the parent hydro-base. Tetrahydroquinoline hydrochloride was found to act more powerfully than the quinoline salt, but could not be used on account of the marked local effects to which it gave rise, the quaternary ammonium salt $C_9NH_{10}(CH_3)_2Cl$ prepared from it, which has a strong bitter taste like that of quinine, like most compounds of this class, had an action resembling that of curare. The methyl and ethyl derivatives of tetrahydroquinoline, however, were found to act as antipyretics, without producing the unpleasant subsidiary effects which characterised the parent base in which the H of the NH group was undisplaced. Kairoline is unfavourably distinguished from kairine by its sharp bitter taste. Kairoline 1 : N-ethoxymethyltetrahydroquinoline and 2 : N-hydroxyethyltetrahydroquinoline, which all exhibit a resemblance to quinine, differ with respect to the length of time during which their physiological action persists, the effect being most persistent in the case of the 1 : N-ethoxy compound. Skraup's quinanisoil is physiologically much less active than its tetrahydride thalline; the hydroxy-compound from which thalline is prepared is poisonous, but loses its poisonous properties and is converted into an antipyretic when the H of the OH group—not that of the NH group—is displaced by CH_3.

Within recent years, under the name *antipyrine*, a further important addition to the stock of antipyretics has been made by Knorr. Antipyrine is prepared by methylating the compound which is formed by condensation of ethylic acetoacetate and phenylhydrazine according to the equation—$C_6H_5.N_2H_3 + C_6H_{10}O_3 = C_{10}H_{10}N_2O + C_2H_6O + H_2O$.
Its formula may be written as follows:—

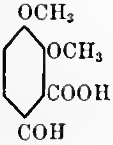


According to Lauder Brunton ("Pharmacology," 3rd ed., p. 825) its "uses" are:—"In febrile diseases generally. It seems specially useful in typhoid fever and phthisis, but is also useful in erysipelas, surgical fever, pleurisy and pneumonia."

The ardour of searchers after new valuable antipyretics among the qunoline and other more complex nitrogenous compounds, however, has not long since received a check in the discovery that so commonplace a substance as ordinary *acetanilide*, prepared by merely digesting aniline with acetic acid, is even preferable to all the artificial antipyretics hitherto discovered; a quarter of a grain is said to have the same effect as one grain of antipyrine. This substance has become enshrouded in an unnecessary halo of mystery by the adoption of the reprehensible practice of re-baptising it *antifebrine.*

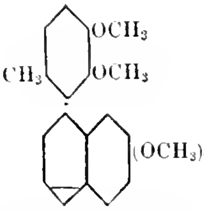
Opium Alkaloids.—The poppy, as is well known, affords a number of alkaloids—narcotine, papaverine, codeine, morphine, thebaine and others of less importance, which are remarkable on account of the variety of types represented by them.

Narcotine, $C_{22}H_{23}NO_7$.—On hydrolysis this alkaloid is resolved into meconine and hydrocotarnine, or by the combined action of hydrolytic and oxidising agents into opianic acid and cotarnine. Opianic acid is now known to be the derivative of 1:2:4 dihydroxybenzoic (protocatechuic) acid of the formula



Cotarnine, $C_{12}H_{13}NO_3$, is a very remarkable compound (v. Gerichten, *Liebig's Annalen*, 210, 79; 212, 165): its relation to pyridine is established by its conversion into cinchomeronic acid, one of the pyridinedicarboxylic acids, and also by its conversion into dibromopyridine. A number of most interesting intermediate derivatives have been prepared from it, but the data are not yet sufficient to finally establish its constitution.

Papaverine, $C_{20}H_{21}NO_4$.—Goldschmidt (*Monatshefte*, 1885, 372, 667, 954; 1886, 485), chiefly from the study of the oxidation products of this alkaloid, concludes that it is a derivative of *phenylquinoline* of the formula



the position of the two OCH_3 groups in the quinoline ring being as yet undetermined.

Codeine, $C_{18}H_{21}NO_3$: *Morphine*, $C_{17}H_{19}NO_3$.—Morphine, according to Beckett and Wright, is a dihydroxy- and codeine a monhydroxy-derivative. Grimaux has succeeded in converting morphine into codeine by acting on it with sodium hydroxide and methyl iodide: *homocodeines*, which, as compared with codeine, present interesting differences in physiological behaviour, may be prepared by means of other iodides. The most remarkable results hitherto obtained are those of v. Gerichten and Schrötter, which appear to show that morphine and codeine are derivatives of phenanthrene, the isomer of anthracene (*Berichte*, 1882, 1484, 2179).

Thebaine, $C_{19}H_{21}NO_3$, according to W. C. Howard's experiments, is a tertiary base of the formula $C_{17}H_{15}NO(OCH_3)_2$; it is converted into morphothebaine, $C_{17}H_{15}NO(OH)_2$, by the action of concentrated muriatic acid. From recent experiments by Howard and Roser (*Berichte*, 1886, 1596), it appears probable that thebaine may also be related to phenanthrene; from the ease with which the hydroxide prepared from thebaine methiodide undergoes decomposition, these chemists have concluded that the N in thebaine is not present in the form of the pyridine ring, it being apparently essential in the case of ring compounds to add on a paraffin iodide twice in order to obtain the hydroxide which will decompose on heating in the manner which Hofmann has shown to be characteristic of the hydroxides of quaternary ammonium derivatives.

The foregoing account is but the faintest sketch of our knowledge of the alkaloids, but I trust that it will be sufficient to make clear the importance of the issues involved in the inquiry into their nature, formation and uses, as well as to give some idea of the difficulties to be encountered and overcome; and also that it may aid in showing that the chemist at the present day requires to have been as carefully-trained, and to be as fully equipped intellectually, as a member of any other learned profession: in plain terms, that a couple of years spent in acquiring practice as an analyst does not suffice to make a youth a chemist.

I know of no other branch of chemical inquiry which presents problems of the same magnitude or so fraught with interest, for it cannot be doubted that when we shall have succeeded in determining the structure of typical alkaloids and shall have gained an insight into the true nature of their physiological functions, our power of alleviating human suffering will be increased to an enormous extent.

It may be asked in conclusion: What part are we taking in this inquiry; are we doing our duty; are we even aware what is our duty? The present generation are working mainly on foundations laid down by Anderson and also by Greville Williams. Matthiessen, in conjunction with Foster and subsequently with Alder Wright, made the first systematic attempt to determine the constitution of an alkaloid, and had he lived English chemists would undoubtedly have undertaken a far larger share of the work; Wright and his fellow-workers have since rendered most important service in the investigation of certain of the opium alkaloids, and of those separated from the aconites and veratrums; the intimate connection between chemical constitution and physiological action was first established by the classical research of Crum-Brown and Fraser: but of late years English workers have been all but silent in these matters, and what is most remarkable, we have always devoted ourselves solely to the analytic examination of alkaloids. Synthetic chemistry, which during recent years has developed in so marvellous a manner in the German schools, has been all but neglected by us.

DISCUSSION.

The CHAIRMAN said the meeting had to thank Dr Armstrong for a paper of most unusual interest—a paper so pregnant with both information and suggestion that it was difficult to deal with it briefly. A clear summing up of some of the most valuable researches of modern chemistry had been given. Dr. Armstrong had said truly that England had dropped behind in these researches. He would suggest that restrictive legislation had prevented the possibility of experiment on living creatures, and, therefore, the only really useful method of investigating the physiological action of these bodies. That had, in his opinion, much to do with England's present position on this question. Unless English investigators were prepared to face the ordeal of the "ticket of leave," the proper investigation of the effects of these bodies must be left to other countries whose legislatures were less swayed by their feelings; and all that was left to English chemists was to study the researches of others. He had been appealed to recently by a gentleman who believed that he had discovered quinine; but when he found that gentleman entirely ignorant of so well-known a body as coniine, and of the work of Caro and Graebe, he decided that that was not the quarter in which such work could have been done. When one considered these bodies, which were so easy to analyse and so difficult to reconstruct, one appreciated the value of the work for which we had to thank German chemistry.

Dr. C. R. ALDER WRIGHT could not let the opportunity pass without thanking the author for the enormous amount of valuable information conveyed by his paper. He could not but cordially endorse the remarks of Dr. Armstrong and the Chairman as to the deleterious effect which "grandmotherly" legislation had had on work of this sort. It was nearly twenty years since, while under Dr. Mathieson, his attention had been drawn to the very peculiar effects resulting from slight changes of composition in alkaloids, but the matter was deeply impressed on his memory by the fact that he was the unfortunate individual who first suffered from the curious change produced in morphia by the mere removal of a molecule of water. The result was the production of apomorphine, the action of even a fraction of a milligramme of which body on the human system was most remarkable. He could recall now with amusement how everybody, from the principal down to the laboratory man, suffered in a very distressing manner from what is best described as a sea-sickness. No one could make out what was the cause of this, until it was discovered that a tube in which morphine had been sealed up with hydrochloric acid had burst. The contents had dried up and blown about the place, and it was this dust, breathed in with the air probably, which had caused their discomfort. That was a case in which a very limited amount of change in the construction of the molecule produced a great difference in its action when taken internally. In this instance the nitrogenous part of the molecule was not affected, the change consisting only in the removal of the elements of water. Dr. Armstrong had remarked that the addition of four atoms of hydrogen to a trebly-linked base containing a nitrogen atom in a pyridine derivative produced a material change in the physiological properties of the substance; and he (Dr. Wright) had observed analogous changes in other alkaloids. For example, the addition of two atoms of hydrogen to the base cotarnine (derived from narcotine by splitting up) converted it into the far more active body hydrocotarnine.

Dr. Stevenson desired to express the deep gratification with which he had listened to the author's very lucid summary of the vast amount of important matter relating to the subject with which he had dealt, the mere reading of which must have been a work of great labour and time. He had carefully studied Brieger's monographs, and considered his work to be far in advance of anything previously done in the same direction. His careful analysis of products obtained by the putrefaction of animal bodies had placed on a satisfactory basis matter which had before been highly problematical. Previous observers in the same direction had obtained products from the putrefaction of various bodies by very rough processes, which must of necessity have led to the hydrolisation of the putrefactive products; but the great amount of care which characterised Brieger's work on the alkaloids warranted chemists in accepting his results with confidence. What had struck him with regard to Brieger's products had been their great simplicity, judging from the number of chemical atoms implicated in the molecule. Tetanine differed from the others in that it appeared to be a much more complex body and to produce effects much more sharply marked. Probably Brieger himself, however, would be inclined to attach some doubt to the formulæ of his earlier described products, and would wish to have their optical properties investigated. He looked for great advances in the direction indicated by Dr. Armstrong. Where one met with an optically inactive body, productive of very little physiological effect, it might be split up into other and physiologically active bodies. He could speak personally of the immense difficulties thrown in the way of chemico-physiological work by the legislation alluded to by the President.

Mr. Crowder, while feeling unable to discuss the subject dealt with by Dr. Armstrong—since his study of organic chemistry had been limited—yet felt bound to point out to those gentlemen who had complained of the hindrance to their work resulting from the operation of the Anti-Vivisection Act, that there was another side to the question. He for one could not admit that they had any moral right to interfere with the lives and the happiness of the lower animals.

The Chairman said: There being no hostile criticism of the paper, he need not call on Dr. Armstrong to reply. He was himself responsible for the remarks about the Anti-Vivisection Act. He did not desire to enter on so perilous a field of discussion, but he was decidedly of opinion that researches having the benefit of mankind as their object were justifiable; and, when he found a relative materially the better for the administration of certain bodies, previously tried on the lower animals, he felt thankful to those gentlemen who had first made dogs uncomfortable.

◆

ON THE CORRECT ANALYSIS OF PLAIN AND AMMONIATED SUPERPHOSPHATES.

BY JOHN RUFFLE, F.I.C., F.C.S.

In my paper read before the London Section of the Society, 16th May, and appearing on page 327 of this Journal, current volume, it was shown:—

1st. The acidity of ordinary superphosphates and of ammoniated superphosphates is due to phosphoric acid (as free acid or as monocalcium phosphate), and not to sulphuric acid; there is, therefore, no free sulphuric acid in such manures.

2nd. The soluble P_2O_5 exists as monocalcium phosphate but to a minor degree; the remainder is free phosphoric acid.

3rd. In ammoniated superphosphates monocalcium phosphate exists in such small amounts that practically it may be ignored.

On page 331 the table shows the soluble P_2O_5 as the monocalcium salt and as free acid, which in their amounts and relative percentages are exhibited here on Table I.

TABLE I.

	Carolina.		Sombrero.		Spanish.		Curacao.	
Soluble P_2O_5 as monocalcium salt	1·99 —	36·62	10·28 —	61·63	1·82 —	11·95	8·21 —	45·05
„ free acid	8·69 —	63·38	6·40 —	33 37	13·40 —	88·05	10·05 —	54·95
	13·68	100·00	16·68	100·00	15·22	100·00	18·29	100·00

Thus of the soluble P_2O_5 only from 11·95 per cent. to 61·63 per cent. can at the outside be present as the monocalcium salt, and this only by giving it the full benefit of all the soluble CaO found in the solutions referred to in second table, p. 330. Along with the soluble P_2O_5 were found SO_3 and CaO in solution; if there be no free SO_3, this soluble SO_3 should have its due amount of CaO allotted to it, in which case we find there is only enough CaO left to give the following proportions of the monocalcium salt and free acid, the latter naturally rising as the former is lowered. By calculation from the second table, page 330, we find there was of soluble SO_3 in proportion to the soluble P_2O_5, as in Table II. So that if, as was assumed in my first paper (for purposes of arriving at the combined water and "moisture"), all the soluble CaO were combined off as mono-salt, or if as now the SO_3 in solution were assumed present as dissolved calcium sulphate, the soluble conditions of the soluble P_2O_5 would respectively be as in Table III.

TABLE II.

Soluble P_2O_5.	Soluble SO_3.	Needing of CaO to form $CaSO_4$.	
CAROLINA—			
13·68	0·21	0·14	Deduct this 0·11 from 1·97 CaO of the mono-salt, page 331, leaves 1·83 CaO to form mono-salt with 4·61 of P_2O_5 instead of 4·99.
SOMBRERO—			
16·68	0·18	0·33	Ditto from 4·04 leaves CaO 3·71 with 9·40, against 10·28.
SPANISH—			
15·22	0·60	0·42	Ditto from 0·72 leaves 0·30 CaO with 0·76 instead of 1·82.
CURACAO—			
18·29	0·17	0·32	Ditto from 3·25 leaves 2·93, with 7·42 instead of 8·24.

It is in every degree probable that the soluble SO_3 is present as calcium sulphate.

The whole object of the manufacturer in introducing the SO_3 to the calcium phosphate is that the SO_3 shall attack and combine with the CaO, and free the P_2O_5. The SO_3 is present in less quantity than is necessary to combine with all the CaO, and there is no reasonable ground why the SO_3 should of the three molecules of CaO belonging to the calcium phosphate attack and combine with two only (as is very commonly presumed), and not proceed to also attack the third. On the contrary, the fact that there is not sufficient soluble CaO to form a mono-salt with the soluble P_2O_5 is proof that the SO_3 has attacked the third molecule of CaO of the calcium phosphate and more or less combined with it; doubtless it would proceed to do so completely, and if present in sufficient quantity would succeed so that the manure would contain all its soluble P_2O_5 as free phosphoric acid. But the manufacturer stops before reaching this point, so as to retain a good dry condition for his produce; and indeed the whole art of the manure manufacturer hinges on his ability to introduce the maximum quantity of O.V. and water, whilst keeping to a good marketable condition.

	13·68	100 00	16·68	100·00	15·22	100 00	18·29	100·00

The soluble P_2O_5 varying from 4·99 per cent. to 56·35 per cent., against 11·9 per cent. to 61·63 per cent. in Table I.

Such being the condition of affairs regarding the SO_3 in the manure, it is evident that the whole of the SO_3 in a plain superphosphate should be combined off and stated as calcium sulphate.

Now it is usual in writing out an analysis of a manure to combine off as much CaO as will form a mono-salt with the whole of the soluble P_2O_5; add this to the CaO of the insoluble phosphate, and the sum deduct from the total CaO, calculating the balance as calcium sulphate, and stating this in the report (no mention being made of any further SO_3). Such amount is much too low.

Any manufacturer can at once see practically that such a way of accounting for the SO_3 put in the manure is far too insufficient. On reference to Table VI. we see that the calcium sulphate, as ordinarily put down, would be respectively—

TABLE IV.

	Carolina.	Sombrero.	Spanish.	Curacao.
	%	%	%	%
Calcium sulphate according to usual method of stating analysis	36·61	39·36	31·77	43·01

To make a ton of superphosphate in each of these cases would, according to the SO_3 of this calcium sulphate, require—

	Carolina.	Sombrero.	Spanish.	Curaçao.
Of O.V.	5¼cwt.	5⅝cwt.	5cwt.	6½cwt.

amounts which the practical man will at once recognise as hopelessly insufficient.

For the "combined water and organic matters" of an analysis it is usual to burn a portion in a platinum dish; from this deduct the loss found at 212° F., and the remainder, minus one half of the "biphosphate," is the amount put down. But as the monocalcium salt is not present as assumed, the "half of the biphosphate" is quite unwarrantable. Further, the heating drives off the soluble P_2O_5, so that this method is without any good basis and totally unfit to be put forward as a chemical determination of these constituents.

To show the results obtained by this method the figures in Table V. (p. 493) are quoted, being those obtained by this method on the prepared superphosphates.

Superphosphates as a manure are valuable on account of the calcium sulphate and the soluble P_2O_5 they contain, but owing to the low money value of calcium sulphate and high money value of the soluble P_2O_5 they are sold wholly on the percentage of soluble P_2O_5 present, without any regard to its existence as monocalcium phosphate or any other form. There is therefore no necessity to attempt to state the monocalcium salt; let this then be abandoned, and only the amount of soluble P_2O_5 be specially stated, as this important item can be arrived at accurately.

TABLE V.

	Carolina.	Sombrero.	Spanish.	Curaçao.
Total water and organic matter (page 329).................	21·30	21·87	21·66	23·99
Loss at 212° F.	20·16	18·95	17·71	13·01
Combined water and organic matter left in after 212° F.......	4·20	5·92	6·92	10·98
Combined water and organic matter found by above method	4·51	3·92	3·41	1·62

A simple plan will then be to conduct the analysis thus:—

(a) Moisture.—Estimate by calcium chloride method in vacuum of an air-pump.
(b) Soluble P_2O_5.—By direct determination.
(c) Insoluble Phosphate.—By direct calculation from the amount of insoluble phosphoric acid, after evaporation to dryness with HCl and re-solution with HCl.
(d) Calcium Sulphate.—Determine the whole SO_3 present, and calculate this into calcium sulphate (anhydrous).
(e) Sand.—Matters insoluble after above evaporation to dryness with HCl and re-solution in HCl.
(f) Combined water and organic matters, etc.*—Difference undetermined.
(g) Alkalis, Magnesia.—Amounts as determined.

By this plan no more work will be introduced than is done at present, whilst the statements *a*, *b*, *c*, *d*, *e*, and *g* will be true from direct determination, and the commercially unimportant "combined water and organic matter" will not be attempted, so false statements be avoided.

To show comparison between the old and new methods, the superphosphates, as tabulated on page 329, are put down in Tables VI, and VII., first the old, then the new.

Under the old method the amounts put down under the four heads of moisture, combined water and organic matter, biphosphate, and calcium sulphate are untrue. During the last year or two chemists have endeavoured to shelter themselves from the charge of inaccuracy on the heading of "Moisture," by writing it "Moisture (loss at 212° F.)," and if questioned, replying that it was "loss at 212° F.," which, as it was to them an unknown quantity, was simply a way of owning their incompetence to determine the moisture correctly; whilst they yet had not the consistency to abandon the term "Moisture." With the other three headings chemists have simply followed each other, without any attempt to check their inaccuracy.

Under Table IV. reference is made to the amount of O.V. presumably used. Now the sulphate of lime in Table VII. shows that to make a ton of these superphosphates there were used respectively of:—

	Carolina.		Sombrero.		Spanish.	Curaçao.
O.V.	6½cwt.	..	6¾cwt.	..	6½cwt.	7½cwt.

amounts which a manufacturer will see is practically correct, producing exactly one ton, and, making allowance for the small mixings made for this research and the small quantities of acid such will carry as compared with the usual wholesale mixings, and very different to the quantities (cwts.) of Table IV.

USUAL WAY OF SHOWING THE COMPOSITION OF SUPERPHOSPHATES.

AMMONIATED SUPERPHOSPHATE.

A striking difference exists between plain and ammoniated superphosphates, in that the latter contain in proportion to the soluble P_2O_5 much less soluble CaO than the plain.

Thus the plain contain of soluble P_2O_5 and soluble CaO, calculated from second table, page 330:—

---

* This will also include the uncombined CaO, etc.

TABLE VIII.

	Carolina. per cent	Sombrero. per cent.	Spanish. per cent.	Curaçao. per cent
Soluble P_2O_5	13·68	16·68	15·22	18·29
,, CaO	1·97	4·01	0·72	3·25

Whilst the ammoniated superphosphates, calculated in the same way from second table, page 332, have:—

TABLE IX.

	3 per cent.	6 per cent.	9 per cent
Soluble P_2O_5	15·02	13 05	11·66
,, CaO	0·38	0·09	0·13

Owing to the sulphuric acid combined with the ammonia, it is impossible to calculate the calcium sulphate from the total SO_3, as this would give results in excess of the truth.

This objection would hold good not only in the special instances here quoted, but be equally valid in all cases where a nitrogenous material is put through the mixer with O.V. and a phosphate, because more O.V. is used than is needed for the phosphate alone, whilst if ammonium sulphate be added, such calculation would of course become inadmissible, and it must be borne in mind that the addition of ammonium sulphate is a very usual and valuable procedure.

The soluble CaO, even if all combined off as monosalt, is so small that it could be ignored, as shown by table on page 333. Small as it is, some of it is without doubt due to dissolved calcium sulphate, so that from this double consideration the existence of CaO as monocalcium phosphate can in these manures be wholly passed over, and the total CaO, less the CaO of the insoluble phosphate, be calculated out to calcium sulphate.

TABLE X.

	3 per cent.	6 per cent.	9 per cent.
Calcium sulphate as usually arrived at as in Table XI.	37·66	32·30	29·27
Calcium sulphate by total CaO, less CaO of insoluble phosphate	45·17	39·70	36·31

For the other items proceed as with plain superphosphates.

Ammoniated superphosphates are valuable on account of the soluble P_2O_5, the nitrogen and the calcium sulphate they contain. The high value of the first two regulates the selling price. All chemical manures being for analytical purposes usually treated and stated the same way as a plain superphosphate, the results in those ammoniated as obtained in the usual way, and by methods as now proposed, are put in next column in Tables XI. and XII., for comparison.

Chemical analysis, whilst stating the accurate amount of the important items which regulate the price, should also state the other constituents as near as can be done, and if there be any glaring discrepancies between the amounts stated and the true percentage, any method enabling this to be overcome should be accepted and acted upon. Table XII. illustrates a plan superior to that of Table XI., by showing clearly, readily and accurately those components for which the manure is valued, and being much nearer the very rigid truth.

EXPERIMENTS ON HEISCH'S METHOD FOR DETECTING SEWAGE CONTAMINATION IN WATER.

BY FRANK E. LOTT, F.I.C.,

Associate of the Royal School of Mines.

HAVING in 1877 commenced a series of experiments for the purpose of testing the value of the so-called "sugar test" for sewage contamination, introduced by Mr. Heisch in 1870, and having followed out one or two special experiments which I have not seen before mentioned, I have taken advantage of our Association to make them public, hoping that my imperfect work may induce others with more time at their command to further investigate this interesting subject.

I will first explain the test as originally introduced by Mr. Heisch :—He says : "A mixture of 6oz. of sewage-contaminated water with 10gr. of crystalline cane sugar kept in a warm place developed a turbidity containing small spherical cells with, in most cases, a very bright nucleus. After the lapse of some days these cells gradually grouped themselves together in bunches, something like grapes ; they next spread out into strings with a surrounding wall connecting the cells together ; the original cell walls then seemed to break and leave apparently tubular sort of threads branched together." He also says : "The cells of these germs when thus developed are distinct evidence of sewage contamination, and the germs producing these cells are not removed by filtration through the finest Swedish filter-paper, neither are they destroyed by boiling for half-an-hour."

Shortly after this paper appeared Professor Frankland replied at some length in a paper on "The Development of Fungi in Potable Water," proving the fallacy of the above conclusion. He says, according to a paper in the *Journal of the Chemical Society* on "Fungi and Fermentation," by Mr. Bell : "My own experiments completely confirm Mr. Heisch's observations, with two important exceptions—viz., that the fungoid growths were not peculiar to water contaminated with sewage, and secondly, the germs from which they originate are present in all waters which have been even momentarily in contact with the air."

He then explained a series of very interesting experiments from which he concludes as follows :—"It is thus evident that the addition of minute traces of a phosphate, either as sodic phosphate, white of egg, or animal charcoal, at once determines these fungoid growths in saccharine water, which before exhibited no tendency to develop them." It was the consideration of Dr. Frankland's experiments, together with the knowledge that this method of examining waters was considerably practised, that led me to undertake the following experiments :—

My first experiments consisted in simply following out this test with waters from shallow and deep wells, and I had the good, or perhaps I ought to say the bad, fortune to have the water from several sewage-contaminated wells to experiment upon, and several samples of waters from wells which there was good reason to believe were directly connected with cases of fever—as an example, one shallow well-water (marked 18) yielded in two days a vigorous fermentation and strong odour of sulphuretted hydrogen, which on the third day was hidden by the disgusting odour usually accompanying butyric acid ; a considerable accumulation of flocculent masses of zoogl∞ated bacilli proved to be almost entirely clostridium butyricum, or, according to Van Tieghem, bacillus amylobacter. As this organism is of considerable interest in connection with these experiments, the following will not be out of place :—In a paper on "Glycerin Ferment," in the *Ber. Deut. Chem. Ges.*, Fitz thus describes what he names "butyl bacillus" : "They are cylindrical cells which increase by elongation and fission ; at one end of the cell a bright spot is formed, which is surrounded by a membrane constantly becoming more indistinct ; the rest of the mother cell grows paler and paler, and finally disappears entirely, only the short cylindrical resting spores with broad dim outlines and shining contents remain. It is two micro-millimeters in diameter and five or six long, and forms almost pure butyric alcohol when grown in glycerine. The contents of the cells are partly coloured by iodine of a violet approaching black, either the whole contents or single isolated patches of it (two or three), or sometimes only one small spot." I might add that this reaction with iodine does not take place at all stages of the growth of this organism. It depends also, to a great extent, upon the nourishing medium.

The results of these experiments will be seen on reference to Table I. on next page, in which I have given a few estimations of some waters experimented upon and the reactions of these waters when submitted to this test. It will be at once seen that the majority of these waters are very seriously contaminated. I would more especially ask you to follow the lines marked P_2O_5, and butyric fermentation, and see how far I am justified in saying the results corroborate Dr. Frankland's.

In the first place, I have a very hard Burton water taken from a tube 150ft. deep in the marl marked D.B., side by side with a fairly soft one, S.W., which is the South Staffordshire Water Works Company's supply to Burton, and in each case the P_2O_5 occurs only in traces and the butyric fermentation is absent. Under the head shallow wells are a number of samples mostly of Burton waters. The water marked N_2 is from a Burton shallow well carefully made, drawing water only from the surface of the impervious strata. The two columns A and B are analyses at different dates showing a very considerable variation and increased contamination in the latter sample marked A ; here we find the butyric fermentation and amount of phosphoric acid agreeing. L is a somewhat similar sample, though in this case as in the next two samples N, A and B, the wells were not carefully constructed, as they collected water at various points throughout their depth, and the well from which these two latter samples were taken was known to be contaminated by sewage.

The next two columns, 18, are samples of the contaminated shallow-well water before referred to, and it will be noted that there is a considerable variation in the analyses at different dates as regards the contamination. No. 274 is a deep well at an old country house, and the quantity of chlorine indicates a very extraordinary amount of contamination ; here, as in the other cases, the phosphoric acid and butyric fermentation agree together. The next three samples are from Burton shallow wells all seriously contaminated, but containing only traces of phosphoric acid. They exhibit no butyric fermentation.

In connection with the analysis 280, I would draw attention to a note on the free ammonia.

Four weeks after taking this sample, which was quite bright and clear, the free ammonia was reduced to less than 0·1, and nitrites before absent were present in considerable quantity. Two months later the free ammonia was 0·05, nitric acid 23·5, and nitrites entirely absent, proving the presence of the nitrifying organism or organisms in full activity in a sample which remained quite bright.

ON THE GROWTH OF THE BUTYRIC FERMENT.

EXPERIMENT VI.

(Three Quarter-Litre Bottles of Deep Bore Water, D.B.)

Date. 16–2–'78	A.	B.	C.
16–2	+ 1·3grms. cane sugar. + 0·2grm. $POHONaO_2$ —	+ 1·3grms. cane sugar. + 0·2grm. $POHONaO_2$ + 0·5grm. NO_2KO	+ 1·3grms. cane sugar. + 0·1grm. $P_2O_2NH_4O_2$ + 0·5grm. NO_2KO
19–2	Gas evolved, acid smell active M. Aceti.	Acid smell. Short rod bacteria.	Acid smell, very active B. Subtilis. Long wavy leptothryx forms.
20–2	Butyric fermentation chains of oval cells.	—	M. Aceti in single cells. Irregular large Sacc. Pastorianus.
21–2	Chains of nucleated cells Clos. Butyricum.	—	No B. Subtilis forms, but a few Clos. Butyricum.
26–2	Large number of nuclei alone.	Jointed bacteria.	Large amount of nucleated S. Minor. A few cells of Clos. Butyricum.
4–3	Masses and rows of bright nuclei.	Thick granular bacteria.	Granular Sacc. Minor. A few bacilli forms.
7–3	Chains of nuclei. Groups of empty sacs, very transparent.	A few bright nuclei. Leptothryx forms of bacilli.	Healthy Sacc. Minor. [Grew well as a bottom ferment in beer wort. Exp. XII.]

EXPERIMENT VII.

(Two 100cc. Pasteur flasks with distilled water. 0·5grm. Cane Sugar and 0·1 $POHONaO_2$ sterilised.)

21–2–'78	1.	2.
21–2	+ 2 drops of solution, A, Exp. VI.	+ 2 drops of a putrid beer containing thick deposit of "chain vibrios."
26–2	Active butyric fermentation, healthy growth of Clos. Butyricum. NOTE 6.	No sign of Clos. Butyricum.

22–2–'78

EXPERIMENT VIII.

Deposit from A, Exp. VI., placed in two small Pasteur flasks containing 1 beer, 2 wort, examined at intervals during the following month. No butyric fermentation, all cells of Clos. Butyricum dead.

EXPERIMENT IX.

23–2–'78.	I.	I.*a*
23–2	250cc. bottle + water No. 18 + 1·3grms. cane sugar + 0·2grm. salicylic acid.	100cc. bottle + water No. 18 + 0·5grm. sugar.
25–2	—	Slight deposit.
4–3	—	Healthy growth; Clos. Butyricum 10% nucleated; free nuclei SH_2 and butyric fermentation.
8–3	—	Fermentation very active; 70% cells nucleated.
11–3	Slight dimness.	No further activity; cells less regular, all nucleated, lengthy and bent.
18–3	Milky; no smell.	—
30–3	Poured off liquid and added 1% solution of glycerin.	—
10–4	No growth of Clos. Butyricum.	—

6–3–78

EXPERIMENT X.

(A Quarter Litre Bottle of Water, D.B. + 1·3grm. Cane Sugar + 2cc. liquid, and deposit from A, VI.)

8–3 Gas evolved. Growth of Clos. Butyricum.

11–3 Butyric fermentation over, SH_2 in bottle. Full of shrunken zooglœated Clos. Butyricum. Added 0·5grm. $POHONaO_2$. Little further activity.

NOTE 6.

6-3-'78. EXPERIMENT XI. NOTE 6.

6-3 A 100cc. Pasteur flask, with 50cc. distilled water, 0·5grm. of cane sugar and 3cc. of solution and deposit 1.*a*, Exp. IX.

8-3 Cells of Clos. Butyricum spores, etc.; large number of irregular-sized circular nucleated cells.

11-3 Zooglœa of short thick bacteria; spores of Clos. Butyricum. Added 0·5grm. $POHONao_2$ + 1grm. sugar.

11-3 Further growth chiefly nucleated circular cells = saccharomyces.

EXPERIMENT XV.

(Three Quarter-Litre Bottles.)

26-3-'78	3.	2.	1.
26-3	Water No. 18 + 1·2grms. cane sugar. Kept neutralised with lime water.	Distilled water + 0·2grm. fused $P_2O_5Amo_2$, boiled and added 1grm. sugar.	Distilled water + 0·2 $POHONao_2$, fused, boiled and added 1grm. sugar.
27-3	Dim.	—	—
28-3	Cloudy, film on surface and at bottom consisting of zoogleated masses of short bacteria, bright spores and minute transparent sacs.	—	—
30-3	Active butyric fermentation. Thick deposit of short, straight bacilli, 70 per cent. nucleated indistinct cells, turned blue with iodine not the nuclei. Neutralised.	Slight dimness and deposit of small circular (Sacc. minor) and oval cells.	Clear.
1-4	Active butyric fermentation, worn crystals, long nucleated cells coloured by iodine. Neutralised.	Zooglæa of Clos. Butyricum non-nucleated, and not coloured by iodine, granular saccharomyces; acid.	Clear.
3-4	Nuclei more distinct.	—	—
5-4	Cell walls fading; nuclei very bright. Faded cells not acted on by iodine.	S. minor in quantity, budding. Zooglæa of bacilli; no reaction with iodine.	Clear. NOTE 6.

TABLE III.

Of 40 samples of water taken by the Rural Sanitary Inspector (Burton-on-Trent) from wells used at houses in which fever or some other zymotic disease had been prevalent, when submitted to the sugar test:—

6 Remained unchanged.

8 Became dim within six days, but underwent no further change.

5 " " with some peculiar woody, sweet or sour smell.

5 Became dim on the second day, and turbid or milky, with a sour smell on the fourth or fifth day.

3 Became dim on the second day, with butyric smell.

7 Dim within 24 hours, and butyric smell and gas on fourth or fifth day.

6 Dim within 24 hours, and butyric smell and gas on second day.

I much regret having been unable at the time to isolate the organism and submit it to further investigation.

I failed to detect any organism with a microscope magnifying 400 diameters.

I might observe that these three wells are, in all probability, contaminated by garden drainage, and draw a large amount of their supply from an old river course, largely filled by peaty matter and partly built over.

53 is a somewhat similar sample, but from a locality nearer the old river course above referred to, and contaminated by surface drainage. The amounts of chlorine and nitric acid in this sample are both excessive.

60 is a mixed sample of deep and shallow well waters; the amount of chlorine is considerable.

162 is a tube drawing water only from the surface of the impervious marly strata, and, therefore, not likely to be contaminated by *fresh* surface drainage, though evidently seriously contaminated.

My second series of experiments was on the action of various mineral salts on the growth of different bacteria, and more especially on clostridium butyricum. The results will be found in Table I. on the line below the one marked butyric fermentation,—from which it will be seen that the simple addition of phosphate of soda to almost any quality of well water set up active butyric fermentation,—in Notes 2, 4 and 5 on the same table, and in the tables of experiments.

NOTE 6.—The difference of the reaction in the cases (Experiments 7, 10 and 11) from that quoted in Note 5 and Experiment 15, I attribute to the fact that in these cases the cells of the butyric ferment were added in a state of full activity, whereas in the latter cases only the dry spores would probably gain access; though possibly the amount of the liquid added (2 drops, 2cc. and 3cc) may have been sufficient to alter the composition of the whole and enable the organism to grow.

A third series of experiments on waters thought to be impure by the Rural Sanitary Inspector of Burton, is also added as throwing some light on this subject. (See Table III.)

I have no doubt that the last four classes, including 21 out of the 40 samples, were very bad; and in some cases, in the two last classes, subsequent investigation proved the direct contamination of the wells by closet drainage.

All these experiments are entirely in accord with Dr. Frankland's, and my only reason for bringing them forward is, that being applied to potable waters, they are of some interest as indicating how far this test may be looked upon for information as regards the purity of such waters; on this head my experiments would lead me to conclude that—

(1.) Any water undergoing butyric fermentation when simply treated with cane sugar and kept at a temperature of about 80° F., may be at once condemned as unfit for domestic use.

(2.) The single fact of a water not undergoing butyric fermentation is no proof of its purity.

(3.) A water which remains *clear* under this treatment would be certainly less likely to be contaminated by sewage than one which became milky, and I doubt the possibility of unoxidised sewage matter being in a water which remained quite clear.

(4.) The butyric ferment is not perceptibly influenced by the presence of abnormal amounts of chlorine, free ammonia, albuminoid ammonia, sulphates and nitrates in a water, but is a very accurate indicator of the presence of phosphoric acid.

ON THE SEPARATION OF ZINC FROM NICKEL AND MANGANESE, AND THE ESTIMATION OF NICKEL.

BY THOMAS BAYLEY.

A good separation of zinc from nickel and from manganese may be made in a hot solution containing free phosphoric acid. The liquid is mixed with ammonia till a precipitate forms, and a fairly large excess of di-sodium hydrogen phosphate is then added. The solution is next cleared with hydrochloric acid added in drops, saturated with sulphuretted hydrogen, and allowed to stand a considerable time, the gas still passing through it. Zinc sulphide falls as a heavy granular powder and the mixture filters very rapidly. Manganese and nickel appear to be perfectly separated, and no trace of the former can be detected by fusion with oxidising flux. Cobalt has a tendency to go down in small quantity, and if zinc sulphide so contaminated be burnt directly to oxide, the cobalt imparts a green tint to the roasted product. In this way cobalt betrays its presence in many samples of German silver, not only in the phosphate separation, but in cases where the zinc is separated from nickel by precipitation in presence of a large excess of acetic acid. The co-precipitated sulphide of cobalt imparts a pale yellow tint to the sulphide of zinc in the method by phosphoric acid, a dark tint in the other case. Iron is partially precipitated by sulphuretted hydrogen in presence of phosphoric acid. In order to precipitate nickel from solutions (containing phosphoric acid or otherwise), I have found it advantageous to add ammonium sulphide till the last drop renders the liquid alkaline ; this is followed by ammonium benzoate and afterwards by a few drops of hydrochloric acid. In this solution (acidulated with a *feeble* acid) the nickel is completely precipitated. A constant current of sulphuretted hydrogen should be passed through the boiling liquid, and filtration should take place at the same temperature as nearly as possible. In one experiment where boracic acid replaced the benzoic acid a good result was obtained. The precipitated sulphide of nickel may be brought down to Ni_2S by prolonged ignition for an hour with sulphur in a closed crucible, the sulphur being replenished from time to time. But a better plan is to roast the precipitate in a porcelain dish, dissolve it in nitric acid, evaporate, ignite, and weigh as sulphate. The ignition should be effected at very low redness and the dish allowed to cool. The sulphate is then remoisted with sulphuric acid and submitted to a further *short* ignition. Success would appear to depend upon the shortness of the second ignition. Heating to a lower temperature for a longer time, and in the absence of free sulphuric acid has been said to yield a basic sulphate of nickel. This method of weighing nickel has been successfully employed by other chemists.

ON A REACTION OF IRON WITH NITRIC OXIDE.

BY THOMAS BAYLEY.

When an assay of "nitre" in vitriol is made in the nitrometer, an error is caused by absorption of nitric oxide when the vitriol contains iron. The absorption is due to the well-known reaction of ferrous salts with nitric oxide, but the result is the same whether the iron be originally present in the ferrous, or, as is more usual, in the ferric condition. Nitric oxide shaken with mercury and pure sulphuric acid, suffers no absorption, nor does mercury pass into solution in the acid. If, however, a little ferric sulphate be contained in the vitriol, mercury becomes dissolved and the iron is reduced to the form of a proto-salt. Upon copiously diluting the vitriol by admission of air-free water, and subsequently adding a solution of a ferricyanide to the cooled acid liquid, the blue reaction can easily be obtained. That the colouration is not caused by any action of nitric oxide upon the ferricyanide may be demonstrated by boiling off the gas (with suitable precautions) before applying the test. The mercury appears to take no part in the reduction of ferric salt, since the results can be equally well obtained if pure nitric oxide (prepared from $FeSO_4$ and HNO_3) be passed through a set of Geissler bulbs, charged with sulphuric acid containing ferric sulphate. The sulphuric acid in this case, as in the nitrometer experiment, assumes a purple or "raspberry" tint, which is characteristic of the reaction when it takes place in the acid, but not in the aqueous solution. Care must of course be taken to remove air from the apparatus by a current of carbon dioxide. The experiment may also be made in the absence of mercury by means of a nitrometer slightly modified as in Fig. 1.

Fig. 1.

Fig. 2.

The instrument is filled with mercury, and sufficient sulphuric acid admitted to depress the mercury below the lower tap. A little acid containing iron is next passed in, and this is followed by nitric oxide. The lower tap is turned off, and the nitrometer shaken, when the purple tint immediately appears. Even for ordinary experiments the second tap is useful, but it must then be placed at the bottom of the measuring tube, Fig. 2. By turning it, the pressure of the mercury in the ungraduated limb is cut off, and the three-way tap can be manipulated without any danger of drawing in air through the axial channel. The formation of the purple solution referred to above was demonstrated at the meeting by passing NO through bulbs containing sulphuric acid in which a little pure ferric hydrate had recently been dissolved.

DISCUSSION ON MR. TERVET'S PAPER ON "AN IMPROVED APPARATUS FOR THE MANUFACTURE OF REFINED PARAFFIN WAX" (THIS JOURNAL, VI. 355).

MR. GRAY asked if Mr. Tervet considered it an advantage to use the apparatus two or three storeys high, as in the ordinary method of refining paraffin scale it was considered advisable to re-melt and cool the scale between each operation, thereby ensuring better crystallisation of the scale or semi-refined wax. By this means also better sweating was obtained, and the impurities bled out more freely; whereas by Mr. Tervet's apparatus it was simply dropped from one chamber to the other without re-crystallising.

Mr. TERVET, replying, said from the construction of his apparatus it was intended to complete the operation of refining with one crystallisation. As had been explained, the present method was divided into two or three stages. The several cells in this apparatus represented those stages, and it only required that the heat should be properly regulated to obtain a result in all respects equal in quality, and with greatly increased quantity, at a single crystallising. So far as he had been able to find, there was no advantage of re-crystallising at two or three successive stages, as paraffin, long before it reached the "sweating" temperature, lost its crystalline structure, and assumed a fibrous nature which greatly favoured the process of sweating. From the diagrams in the Journal it would be seen that in making refined wax a certain quantity of intermediate paraffin had to be added before the last crystallising. With this apparatus those fractions originally present in the paraffin scale were retained until the material reached the lowest cell of the apparatus, or the point at which the refined article is produced.

◆

DISCUSSION ON MR. DAVIDSON'S PAPER ON "THE ESTIMATION OF IRON IN CHARS" (THIS JOURNAL, VI. 421).

DR. MILNE said he was glad to find that Mr. Davidson had gone into this matter, as, to the sugar refiner, the exact amount of char was a matter of the first importance, and of course a correct method was a *desideratum.* Twenty years ago he had large practice in the analysis of animal charcoals, pan even then the permanganate and bi-chromate processes were rather discarded as being unfitted for the determination of minute quantities of iron. At that time the stannous chloride process was also used, and his own impression was that for the determination of small quantities of iron it was everything that could be desired. He was also glad to find that Mr. Davidson had adopted an extremely classical method of oxidising by means of peroxide of hydrogen, as this was, in his opinion, one of the most elegant oxidising agents that could be wished for, and perhaps the oxidising agent of the future.

Mr. TERVET asked in what condition did the iron exist in chars? He had understood, from a correspondence which appeared in the *Chemical News* some years ago, that a certain proportion of the iron was supposed to exist in the form of sulphide, FeS. But the proportions found were so small, and the interest in the question so great, he should be pleased to know what action the sulphides had upon the sugar or upon the operations of the refinery.

Mr. DAVIDSON, in reply, said that so far as his knowledge went the "tin" process was discredited by some, and he knew of several in the trade who preferred either the "permanganate" or "bichrome" processes to the above-mentioned. Tucker also spoke only of the permanganate process in his book, which was almost the only one in English on sugar analysis. With reference to Mr. Tervet's remarks as to the existence of iron sulphide in chars, he believed it would be difficult to demonstrate its presence. The sulphur was assumed to be in combination with calcium, which was a more likely thing. The objection to the presence of iron in chars was that it passed into the sugars, thus deteriorating infusions of tea with which they would be used.

Journal and Patent[*] Literature.

I.—GENERAL PLANT, APPARATUS AND MACHINERY.

Invention to Purify Water for Steam Boilers by Filtering the same under pressure of Steam through Mineral, Vegetable, or Animal Charcoal. W. Cotton, London. Eng. Pat. 5963, May 3, 1886. 8d.

THE water is forced by a steam injector into the lower part of a vertical cylindrical vessel, where it deposits the carbonates precipitated by the heat. A diaphragm in the upper part of the cylinder carries a filtering material —*e.g.*, coke—through which it passes on its way to the boiler. An escape for steam is provided at the highest part of the vessel.—C. C. H.

Improvements in Filtration. J. G. Lorrain, London. Eng. Pat. 6813, May 20, 1886. 8d.

THE improved filter consists of a number of spherical balls of an elastic substance, such as rubber, and preferably hollow, placed in a vessel of suitable shape between two plates. When the plates are pressed together the spaces between the balls are diminished, and thus the degree of fineness of filtration can be adjusted between that attainable when the balls rest on each other without pressure and the complete cessation of the operation when the interstices between the balls completely disappear. Such a filter admits of being cleansed rapidly and completely.—C. C. H.

Improvements in Filters. G. F. Marshall, Battersea. Eng. Pat. 7088, May 26, 1886. 8d.

THE filters to which the improvements are applicable are the domestic water filters of the carbon block type, and the novelty consists in enclosing the carbon filtering block in a case or cover so as to contain air. Each time the water is renewed in the filter, this space is refilled with air, and it is forced through the block along with the filtered water, which is thus thoroughly aerated.
—C. C. H.

Improvements in Means for Softening and Purifying Water. J. S. Sawrey, London. Eng. Pat. 9227, July 15, 1886. 8d.

THE mixture of the hard or impure water with the reagents, used either in a solid or liquid form, is thoroughly agitated by means of a mechanical agitator, steam or compressed air; in some cases it may be found convenient to combine certain or all of these methods of agitating.—C. C. H.

Improvements in Filter-presses. A. W. Anderson, London. Eng. Pat. 11,244, Sept. 4, 1886. 8d.

THE improvements specified relate to the older form of wooden filter-presses. They consist of (1) forming the cloth like a sack or bag, which covers entirely the filter plate; (2) the combination of this form of cloth with a ribbed filter plate; (3) the use of a screw clip nut of the ordinary form securing the cloth round the central orifice which serves as a passage between the chambers.
—C. C. H.

Improvements in Filter Presses. H. E. Newton, London. From W. Baur, Brooklyn, U.S.A. Eng. Pat. 4425, March 24, 1887. 8d.

THE improvements make provision for the use in a filter-press of such materials as sawdust, animal charcoal or other granular material, as a filtering medium. The chambers are constructed, in the well-known manner, by means of ribbed plates and distance frames. Hoppers are formed on the upper part of the distance frame, for the introduction of the filtering material, and similar provision is made for its removal from the lower part of the frame.—C. C. H.

II.—FUEL, GAS AND LIGHT.

The Influence of the Length of the Photometer on the Resulting Measurements. D. Coglievina. Journ. f. Gasbel. u. Wasservers. **30**, 88.

THE author agrees with Krüss (*Chem. Zeit. Rep.* **10**, 265) that the length of the photometer influences the results, but points out the necessity of taking into consideration the varying quality of the gas in different parts of the same circuit, due to minute and unavoidable leakages. He recommends a round burner in place of a fish-tail flame and the use of a long photometer.
—C. A. K.

Improvements in the Methods and Appliances for obtaining and Cleansing Gas from Coal. T. Nicholson, Abergele. Eng. Pat. 5727, April 27, 1886. 8d.

THE retorts are made airtight, and dried steam is passed through the charge. This is to hasten the process of gasification and increase the yield of gas. A scrubber is dispensed with by passing the gas through a series of small chambers divided by horizontal partitions into three compartments. The topmost of these compartments has a perforated floor, through which water trickles on to the gas passing below. The lowest chamber is for the tar, etc., deposited with the water. The flow of gas is aided by a steam jet.—A. R. D.

Improvements in and applicable to Gas Producers. W. S. Sutherland, Birmingham. Eng. Pat. 7112, May 27, 1886. 8d.

THESE improvements relate to producers of the type described in Eng. Pat. 1784 of 1874, Eng. Pat. 8053 of 1884, and Eng. Pat. 5915 of 1886. The producer is to be provided with a grate which can be moved both circularly and to and fro by means of a lever. Below the grate is placed a wind chest for the introduction of an air blast, and arrangements are also made for a steam supply if desired. A check-valve prevents the gas from being drawn back into the air mains and passages, while a safety valve, consisting of a canvas-rubber disc secured over the open end of a straight lead in the air supply pipe, relieves the pressure by being easily ruptured in case of an explosion.—A. R. D.

Improvements in the Purification of Coal Gas. C. F. Claus, South Wimbledon. Eng. Pat. 7580, June 5, 1886. 11d.

THESE improvements refer to a process for purifying coal gas in close vessels with ammonia only. The gas, previously freed from tar, is passed through a series of scrubbers, consisting of towers packed with porous material, down which trickles the spent liquor to be mentioned hereafter. When the gas has passed through two of the series of say five scrubbers, a quantity of ammonia gas is introduced into the current sufficient to combine with the impurities that the gas is estimated to contain. As the washing liquor is pumped from scrubber to scrubber in a direction contrary to the flow of the gas, it will be seen that the whole of the ammonia (both introduced and originally present in the

---

[*] Any of these specifications may be obtained by post, by remitting the cost price, *plus* postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.........	½d.
Above 8d., and not exceeding 1s. 6d...	1d.
,, 1s. 6d., ,, ,, 2s. 4d...	1½d.
,, 2s. 4d., ,, ,, 3s. 4d...	2d.

gas) is contained into the liquor flowing from the bottom of the last tower. This liquor is carried away to another series of towers forming an ammonia regenerating plant. Here the liquor is first heated to about 200 F., whereby the carbonic acid and sulphuretted hydrogen are driven off, as is also a little free ammonia. This last is absorbed in a tower fed with spent liquor or dilute sulphuric acid, and the two first-named gases go forward to sulphur recovery plant. After the removal of the carbonic acid and sulphuretted hydrogen the liquor is treated with naked steam, which drives off all free ammonia and that existing as carbonate and sulphide. This ammonia is recovered in a condensing or catch-tower, and is available for re-introduction into the scrubbing system as above described. The residual liquor, charged with fixed salts of ammonia, is partly used for feeding the scrubbers, and is partly removed to be dealt with as ammoniacal liquor in any ordinary way.—A. R. D.

Improvements in the Preparation of Ammonia Compounds from Coal Gas. C. F. Claus, South Wimbledon. Eng. Pat. 7582, June 5, 1886. 8d.

In purifying coal gas by ammonia as described by the inventor in patents 7580 and 7584 (see abstracts) the ammonia contained in the crude gas is constantly withdrawn for sale, whilst a quantity or stock of ammonia is kept in circulation for the purpose of purification. The present invention has for its object the convenient and economical removal of this surplus ammonia. This is effected by converting the same without distillation either into ammonium carbonate or ammonium sulphate. The requisite surplus ammonia equal to that contained in the crude gas may be withdrawn either from one of the heating towers or from the tower next it in the form of nearly pure carbonate, whilst for the purpose of recovering the ammonia as sulphate, the first wash-tower or the equivalent sulphuric acid catch-tower may be replaced by one or more lead-lined towers filled with pebbles or the like, down which a regulated quantity of sulphuric acid trickles, or an acid saturator may be interposed between the second wash-tower and the first acid catch-tower.

—D. B.

Improvements in the Purification of Coal Gas. C. F. Claus, South Wimbledon. Eng. Pat. 7584, June 5, 1886. 11d.

This system of purification resembles, in its main features, that described in Eng. Pat. 7580 (see abstract above). The ammonia vapours produced in the distilling apparatus by the action of naked steam upon the scrubber liquors (from which the sulphuretted hydrogen and carbonic acid have been eliminated by a previous heating) are condensed and used for washing the gas in the scrubbers. The two scrubbers last traversed by the gas are served solely by the spent liquor resulting from the distilling plant. Their special function is to recover the ammonia contained in the gas after it leaves the other three scrubbers. In these latter are used the condensed ammonia liquors above mentioned, together with the liquor coming from the two first-named scrubbers.

—A. R. D.

Improvements in the Purification of Coal Gas. C. F. Claus, South Wimbledon. Eng. Pat. 7585, June 5, 1886. 8d.

At the top of one of the scrubbers described in Patents 7580 and 7584 (see preceding abstracts), a quantity of finely-ground sulphur is introduced, more than can be dissolved by the ammonium sulphide present in the scrubber. The advantage claimed is the elimination of carbon bisulphide from the gas.—A. R. D.

An Improved Vapour Lamp for use with Incandescent Mantles. S. Siemang, Vienna, Austria. Eng. Pat. 8097, June 18, 1886. 8d.

This is a lamp for converting liquid hydrocarbon into gas and burning it as such The hydrocarbon is conveyed from its store receptacle by a wick to a gasifying chamber, where it is heated by the combustion of a small quantity of the gas made in the apparatus, and from which it passes in the gaseous form to the burner. Air is allowed to mix with the gas before it reaches the burner. For details the specification must be consulted.—A. R. D.

Improvements relating to the Purification of Gas and the Impregnation of the same with Hydrocarbon or other Vapour, and to Apparatus therefor. G. Symes, Limehouse Eng. Pat. 8484, June 28, 1886. 8d.

The apparatus consists of a casing divided into two chambers by a vertical partition. In the one is placed a series of oxidised iron plates, supported by pivots or trunnions resting in bearings formed in the casing. In the other chamber, perforated iron plates are arranged one above the other, and the spaces between filled with cotton waste or other absorbent material. Upon the topmost plate is situated a perforated receptacle for camphor or other suitable volatile disinfectant. At the top of the casing is a dome with a self-acting valve for regulating the passage of the gas through the apparatus. The gas passes downwards through the first-named chamber, and is freed from sulphur compounds by contact with the oxidised iron surfaces. It is then purified from ammonia, etc., by passing upwards through the cotton waste in the second chamber, at the top of which it mingles with the vapours given off by the camphor in the perforated receptacle.—A. R. D.

An Improvement in Apparatus for Enriching Gas by Admixture of Hydrocarbon Vapour. J. Livesey, London; and W. Whitehouse, Birmingham. Eng. Pat. 9473, July 21, 1886. 8d.

The carburetter is a vessel partly filled with naphthalene and heated by radiation from the burner in the usual way. The aperture by which the naphthalene is charged is closed by a seating carrying a plug. The gas passage from the service pipe lies through this seating, and the plug is so perforated that when in one position the gas passes directly to the burner without entering the carburetter, while, when the plug is in another position, the gas passes through the carburetter. Intermediate positions allow the gas to go both ways in such proportions as may be desired.—A. R. D.

Improvements in Apparatus for Carburetting Air. J. H. Johnson, London. From E. D. Debouteville and L. P. C. Malandin, Fontaine-le-Bourg, France. Eng. Pat. 9598, July 24, 1886. 8d.

The leading feature here is the simultaneous introduction of a jet of hydrocarbon and a thin stream of hot water. The two play upon a dividing surface which distributes the liquid in a thin film over a helical brush, which completes the mixing and assists the evaporation. This introduction of hot water prevents the excessive cooling otherwise produced by the evaporation of the hydrocarbon, and causes the retention of much solid matter, which would otherwise go forward with the gas and limit its field of application.—A. R. D.

An Atmospheric Gas Burner. O. Imray, London. From C. A. von Welsbach, Vienna, Austria. Eng. Pat. 9755, July 28, 1886. 8d.

This burner consists of a tube having its lower portion constructed like that of a Bunsen burner, whilst its upper end spreads out into a chamber of hemispherical form. This chamber is provided with a cover that does not quite extend to the periphery, so that an annular slit is left for the passage of the mixture of air and gas, which forms, when burning, an annular flame. The hemispherical shell is connected with the cover by a number of tubes. These are open at both ends and admit a further supply of air to the interior of the annular flame. As this burner affords very little luminosity but an intense heat, the flame is particularly suitable for an incandescence system of lighting.—A. R. D.

Improvements connected with the Manufacture of Water Gas and other Gases for Lighting, Heating and Manufacturing Purposes, and in Apparatus therefor. S. Levy, London. From G. H. Kohn, Denver, U.S.A. Eng. Pat. 927, Jan. 20, 1887. 8d.

THE apparatus consists mainly of three cylinders. An air blast is forced through fuel contained in the middle one of these, the generator; and the products of combustion are used to heat the other two, which are packed with brickwork. When these are sufficiently heated, steam is forced into one of them, and passes superheated through the still incandescent fuel in the generator. The gas on leaving here may be mixed with a spray of oil, the whole being fixed and rendered homogeneous in the third cylinder.—A. R. D.

Improvements in the Manufacture of Steam and Oil Gas for Fuel and for Illuminating Purposes. A. J. Boult, London. From H. W. Brooks, Philadelphia, U.S.A. Eng. Pat. 2749, Feb. 22, 1887. 8d.

A MIXTURE of steam and oil is injected into a series of retorts built in sections of such shape as to form a serpentine passage. These retorts are provided at intervals with disintegrators consisting of cylinders with perforated sides, having the end opposite to the steam and oil inlet closed. By this means the stream of gas or mixture of oil and steam, passing along the retort is constantly broken up and made to impinge upon the sides of the retort, the result being a fixed gas of great purity and uniform quality.—A. R. D.

Improvements in Apparatus for Enriching Gas. H. J. Siebel, jun., Reading, Penn., U.S.A. Eng. Pat. 2752, Feb. 22, 1887. 6d.

THE gas supply-pipe passes upwards through a box of sheet metal which is partly filled with sticks of naphthalene. The upper portion of this pipe is enclosed within another pipe with an enlarged head, and the burners are placed so near that this is heated by the flames. The gas passes upwards through the supply pipe into the enlarged head of the outer pipe, where it is heated to such a degree that, passing down through the annular space between the two pipes into the carburetting chamber, it causes the disengagement of naphthalene vapours and passes away, mingled with these, by any suitable outlet to the burners.—A. R. D.

Improvements in the Purification of Coal Gas and Apparatus therefor. C. W. Watts, London. Eng. Pat. 3267, March 3, 1887 8d.

IN Eng. Pat. 7585 of 1886 (see abstract, p. 502), C. F. Claus proposes to eliminate carbon bisulphide from coal gas by scrubbing with ammoniacal liquor that has been in contact with solid sulphur. The present invention provides for such sulphurisation of ammoniacal liquor by allowing it to percolate through a mass of sulphur on its way to the scrubber. The sulphur is contained in a tank, and the liquor may be drawn off at various depths, the height at which it stands in the tank determining the sulphur surface exposed and hence, the degree of sulphurisation. —A. R. D.

Improvements in Apparatus for Vaporising and Burning Liquid Hydrocarbons. W. G. Bussey, New York, U.S.A. Eng. Pat. 5026, April 5, 1887. 8d.

THE vaporising chamber, preferably of not less than 25 cubic inches capacity, is made of any suitable metal and is provided with an inlet pipe for the admission of liquid hydrocarbon. Pipes from the upper part of this chamber conduct the vapours to mixing tubes so disposed that the flames proceeding from the tube tops impinge upon the chamber walls. These mixing tubes are simply pipes in which the hydrocarbon vapours mix with air admitted by an aperture in the side or bottom. They may be provided with gauze caps to prevent the return of the flame. When starting the apparatus, oil is admitted to the vaporising chamber, which is then heated by any suitable means. The vapours evolved burn at the tops of the mixing tubes and, besides heating the vaporising chamber, give off heat available for other purposes. The high tension of the gases in the vaporising chambers makes it essential that the hydrocarbon be admitted under pressure.—A. R. D.

Improvements in the Purifying of Hydrocarbon Oils. A. J. Boult, London. From D. M. Kennedy, Petrolia, Canada. Eng. Pat. 6018, April 25, 1887. 4d.

ONE POUND of sulphate of copper, one pound of caustic soda and one pound of common salt are dissolved in two gallons of water and added to forty gallons of the oil to be treated. The mixture is then kept at the boiling temperature in a still for about an hour. By this treatment the oil is rendered pure and free from sulphur, so that it neither encrusts a wick nor gives an offensive smell when burning.—A. R. D.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Decolorisation of Carbolic Acid S. Demant. Zeits. österr. Apoth. Ver. **25**, 150.

CARBOLIC ACID which has turned red may be decolorised by mixing it, after melting, with alcohol in the proportion of 89 parts to 11 of alcohol. The mixture is then crystallised and the red liquid drained from the colourless crystals.—C. A. K.

Influence of Mineral Substances, especially of Lime, on the Dry Distillation of Coal. Knublauch. Journ. für Gas. u. Wasservers, **30**, 55 and 96.

GAS COAL was mixed with 2½ per cent., 5 per cent. and 10 per cent. of ordinary powdered and burnt lime, and in one case with 5 per cent. of silica. The table below shows the difference in yield of the various products per 1000kilos. of coal burnt :—

1000kilos. Coal yielded:		Lime added.			Silica added.
		2·5 p.c.	5 p.c.	10 p.c.	5 p.c.
Gas	cc. more	14·7	20·1	35·3	21·5
Coke	kilos. more	16·8	18·2	17·5	27·4
Tar	„ less	5·2	7·9	9·0	11·8
Ammonia	„ more	0·483	0·608	0·929	0·15
Sulphate	„ more	2·02	2·53	3·88	0·67
Sulphuretted hydrogen.	„ less	1·42	1·58	1·81	0·21

The yields of the various products do not appear to bear any proportion to the amount of admixed substance. The increase in the yield of coke being greater than the decrease in that of tar, it is clear that the gas will contain less carbon, and therefore possess less illuminating power, than when the coal is distilled alone. With 2½ per cent. of lime added, the yield of gas is increased 5 per cent., but its illuminating power diminished 5 per cent. Further, although the yield of coke is increased, it still contains the lime or silica mixed with it, which considerably lessens its value. An increase in the amount of carbon dioxide in the crude gas and a slight decrease in the quantity of cyanogen compounds was observed. The advisability of the addition of lime or silica in the distillation of coal can only be determined by the relative values of the products obtained. —C. A. K.

Preparation of Light Hydrocarbons from Heavy, Dark Residual Oils. F. Redl. Chem. Zeit. **11**, 347.

RIEBECK'S method (this Journal, 1887, 282) for preparing light hydrocarbons from heavy oils consists in the distillation of the latter under pressure. The same result is obtained, without employing pressure, by using a dephlegmator. This is connected with the exit tube of the still and is provided with a tube at its lowest point which leads back to the bottom of the still. By repeated rectification mixtures of liquid hydrocarbons can be separated by this means into light and heavy oils. The draught in the dephlegmator must be adjusted to the surface of evaporation of the still. The yield of light oils is good; the medium oils, for instance, which are too heavy for lighting purposes, being thus completely decomposed into light oils. Paraffin free from oil is not decomposed. The results are greatly influenced by the temperatures and the duration of the distillation.—C. A. K.

New Method for Refining Mineral Oils, Paraffin, Ozokerite and allied Hydrocarbons. F. Redl. Chem. Zeit. **11**, 415—416.

THE oils obtained by the fractionation of crude Russian petroleum are brought into an agitator, where they are well mixed by mechanical means (an air blast cannot be employed) and treated with 20—40 per cent. of petroleum naphtha, of sp. gr. 0·670—0·690. The whole is agitated until thoroughly mixed, when sulphuric acid is added and the agitation continued. The acid separates completely and quickly, and the impurities are readily removed, while no emulsion is formed with the oil, whereby the loss is considerably less than when the old method of purifying by means of acid is used. The oil, after twenty minutes' standing, is then neutralised, in a second mixing apparatus connected with a cooling worm, with caustic soda at 25°, whence it is pumped into a still and the petroleum naphtha distilled off by direct and indirect steam. The last portions of light oil are got rid of by distilling with superheated steam at 180° in a shallow still. The petroleum naphtha used must not consist of a mixture of oils of low and high boiling points, but must be taken from a constant fraction, while the quantity employed depends upon the degree of the purity of the oils treated. The greater the proportion of the naphtha added the less acid is required. Fuming sulphuric acid gives the best results, of which 4 to 7 per cent. is added, at a temperature of 18—24° C. The loss of naphtha is 3½ per cent., but is greater when it consists of several fractions. Oils thus purified can be further decolourised far more readily than when the old method is used, lubricating oils and vaseline being bleached with less loss and by only a fraction of the quantity of the decolouriser generally necessary. The products obtained by this process, which has been tried with crude oils of various kinds, as well as with resins, are purer and lighter coloured than can be obtained by the old method. The purification of ozokerite is effected similarly. It is previously heated, however, to 120°, to remove water and light oils, and after cooling to 75° is treated with 50 per cent. naphtha of sp. gr. 0·700—0·720. The mixture is gently agitated and then the sulphuric acid added. With 10 per cent. of fuming acid an almost white product results, which can be completely decolourised by charcoal. The apparatus employed is similar to that already described. The neutralisation with alkali is effected at 70°. The resulting paraffin forms a shining white mass; the yield of pure substance is 83 per cent., against 60 per cent by the old process.—C. A. K.

The Relation of Petroleum to the Hydrocarbons from Lignite and Coal. G. Kraemer and W. Bottcher. Ber. **20**, 595—609.

THE German petroleum, like the petroleum from Pennsylvannia, Russia and Galicia, consists of two classes of bodies, one of which is not acted upon by concentrated H_2SO_4 or HNO_3 in the cold, whereas the other, with the exception of a small quantity which is polymerised or completely destroyed, dissolves with the formation of sulphonic acids and nitro-products. Besides the hydrocarbons, small quantities of organic acids and sulphur compounds are found, but no bodies containing nitrogen. The hydrocarbons unacted on by acids have a comparatively low specific gravity, not exceeding 0·850 for fractions boiling up to 300°. These form the chief portion of the petroleum and until recently were considered to be paraffins. Later experimenters have shown that, in addition to these, hexahydrides of benzene hydrocarbons occur. To these Markownikow has given the name naphthenes. The authors have found that German petroleum also contains naphthenes. Several of these have been analysed, but with some difficulty, as the bodies readily split off acetylene, which is not oxidised with red-hot copper oxide. The naphthenes, unlike the olefines, do not absorb bromine nor dissolve in concentrated H_2SO_4. Of the existence of these naphthenes the authors cite several proofs. The occurrence of petrolic acid, which is isomeric with the oleic acids, must be regarded as the carboxylic acid of naphthene. This body has the formula $C_{15}H_{28}O_2$. A whole series of homologues of these acids containing smaller or larger quantities of hydrogen occur. On heating the lime salt with soda lime, and distilling under diminished pressure, a hydrocarbon is obtained, boiling at 180° to 230°. It has the formula $C_{14}H_{26}$, and absorbs bromine readily; it is, therefore, no naphthene, but an olefine. From the fact that Perkin's tetramethylenecarboxylic acid yields, under similar conditions, ethylene, it appears to indicate that the latter acid is a lower homologue of petrolic acid.

With regard to the second class of hydrocarbons, the action of sulphuric acid upon them gives a means of separating them quantitatively from the other hydrocarbons. In the oils from Tegern See, 8·7 per cent.; from Pechelbronn, 7·64 per cent.; from Oelheim, 9·37 per cent. of these hydrocarbons were found. The presence of naphthalene was also identified. In the higher boiling fractions, in addition to naphthalene, hydrocarbons with the formula $C_{10}H_{10}$, $C_{11}H_{12}$ and $C_{12}H_{14}$ were isolated by Markownikow. Although apparently related to naphthalene, they cannot be oxidised without undergoing complete decomposition. On reviewing the series of hydrocarbons which occur in petroleum, it is a curious fact that exactly the same are constituents of coal tar, although in different proportions; whereas, in the fraction of petroleum boiling up to 150° only 8 per cent. are dissolved by concentrated H_2SO_4, nearly the whole of the same fraction dissolves in the case of coal tar. Although the indifferent hydrocarbons found in coal-tar cumene are stated by Jacobsen to be paraffins, this class of compounds in coal tar requires further investigation. There is little doubt however, that they are similar to those occurring in certain petroleums. Of the higher boiling hydrocarbons occurring in coal tar—viz., naphthalene, acenaphthene, fluorene, anthracene, phenanthrene, etc., only naphthalene has been found in petroleum. A hydrocarbon, with the formula $C_{10}H_{10}$, supposed to be dihydronaphthalene and its homologues, have been found by Berthelot in coal tar. In the oil obtained by the distillation of lignite, the same series of bodies has been found, although in different proportions to those occurring in petroleum and coal tar, the proportion of the different constituents standing about midway between the two. In view of the fact that the tar from lignite is obtained at a much lower temperature than that from coal, the high percentage of naphthene in certain petroleums might probably be due to the high temperature at which they are formed. Experiment has not confirmed this. In the first place, hydrocarbons soluble in acids can be obtained by heating the insoluble hydrocarbons in closed tubes under pressure, so that the presence of the former may be ascribed to subsequent rise in temperature. But it is otherwise with naphthene. By passing petroleum from Tegern See through a red-hot tube a distillate is obtained which, after absorbing the soluble hydrocarbons by acids, possesses the same composition as previously to heating, so that naphthene was not formed from the paraffin. The authors regard the hydrocarbons absorbed by acids as derived from naphthalene, much in the same way as naphthalene, anthracene, etc., are built up from the benzene nucleus, the latter being obtained by heating the paraffin under pressure.—J. B. C.

Improvements in Apparatus for the Distillation of Coal Shale and other Materials. O. Rose, London. Eng. Pat. 9550, July 23, 1886. 8d.

In this apparatus the description, which does not admit of useful abridgment without the drawings which accompany the specification, (1) the volatile products are removed in accordance with the varying temperatures that the substances to be treated are subjected to; (2) the material is first broken up into convenient and somewhat uniform sizes before it passes into the retort, and that during the time it is being propelled through the retort it is continuously broken up so as to prevent as much as possible its being carried forward in a caked mass; and (3) the objection found, that the receptacle and the gas-tight door as generally used are inconvenient, and, where the machine is automatic in its action, difficult to keep gas and air tight, is removed.—D. B.

Improvements in obtaining Hydrocarbons from Gases. F. Friedländer, Gleivitz; and G. Quaglio, Berlin, Germany. Eng. Pat. 4888, April 1, 1887. 4d.

These consist in an improved mode of recovering the benzene, toluene and naphthalene contained in the gases from the destructive distillation of fossil-coal, shale, petroleum and tar oils and residues. The gases are conducted through thin or very liquid tar in a scrubber, the tar being used for washing until it is completely saturated with hydrocarbons. The absorbed oils are then distilled off, the residual tar being used for painting or roofing purposes, whilst fresh tar is used for washing the gas.—D. B.

Purification of Crude Anthracene. A. A. Vale, London. From the Chemische Fabriks Actien Gesellschaft, Hamburg, Germany. Eng. Pat. 5785, April 20, 1887. 4d.

This invention is based upon the fact, hitherto unknown, that the impurities of crude anthracene, including carbazol, are much more readily soluble in pyridine, quinoline and aniline bases than anthracene. The power of these bases to "enrich" anthracene is so great that they may be used in conjunction with the solvents ordinarily employed for the purification of crude anthracene. Thus, in using a mixture of equal parts of naphtha and tar bases in the proportion of 1 part of anthracene to 2 parts of this solvent, anthracene of about 80 per cent. purity is said to be obtained.—D. B.

IV.—COLOURING MATTERS AND DYES.

Thiophen Green. L. E. Levi. Ber. **20**, 513—517.

Tetramethyldiamidodiphenylthienylmethane $C_4SH_3.CH:[C_6H_4N(CH_3)_2]_2$.—This body is obtained in a similar manner to leucomalachite green by heating 1 part thiophenaldehyde, 2 parts dimethylaniline with a little alcohol, and 3—4 parts $ZnCl_2$, for six hours. The $ZnCl_2$ is added gradually, and if the mass becomes thick, water is added. When the smell of the aldehyde has disappeared, the mass is made alkaline with caustic soda. The product is treated with steam, extracted with ether, and the ethereal solution evaporated. The crystalline residue is recrystallised from alcohol. It combines with HCl, and forms a double salt with $PtCl_4$. The leuco-base combines with picric acid. On oxidation with MnO_2 and dilute H_2SO_4, the leuco-base changes to green. The colouring matter is extracted with hot water, filtered from MnO_2, precipitated with NH_4Cl and NH_3, and the precipitate extracted with ether. This compound is the basis of the colouring matter thiophen green and is a "carbinol" compound of the formula $C_4SH_3COH[C_6H_4N(CH_3)_2]_2$.

Like malachite green, it forms a double salt with $ZnCl_2$. The author has also prepared and analysed the picrate, sulphate and oxalate.—J. B. C.

Mono- and Ditolylamine. V. Merz and P. Müller. Ber. **20**, 544—550.

By the action of zinc bromide, ammonia and ammonium bromide upon *p*-cresol, the authors obtain mono- and di-*p*-tolylamine. Ammoniacal zinc chloride and NH_4Cl serve equally well. Paracresol was heated with three times the weight of ammoniacal zinc bromide, and an equal weight of ammonium bromide, for three hours to 300—310°. The product was repeatedly extracted with dilute HCl, the residue with ether, and finally with water acidified with HCl. The ethereal extract consisted of *p*-toluidine and di-*p*-tolylamine.

The following determinations were made with 20grms. of *p*-cresol, in I. and II. with 60grms. of ammoniacal zinc bromide and 20grms. of NH_4Br, and in the IV. and V. with 80grms. of ammoniacal zinc chloride, and 20grms. of NH_4Cl. The temperature in the case of I. and II. was 300—310°, and in other cases 330—340°; duration of experiment 40 hours.

	I.	II.	III.	IV.	V.
p-Toluidine	25	25	24·5	45	41·5 per cent.
Di-*p*-tolylamine	40	37·5	41	31·5	30 „
Carbonaceous matter	2·5	3	5·5	6	8 „
Unchanged *p*-cresol..	27·5	30	22	11	10·5 „

By similar treatment of *o*-cresol, the following results were obtained. (Temperature of I. 300—310°; II. 315—320°; III. and IV. 330—340°):—

	I.	II.	III.	IV.
o-Toluidine	28	50·3	48	55 per cent.
Di-*o*-tolylamine	2·5	10	7	7·5 „
Carbonaceous matter	2·5	3	6·5	5 „
Unchanged o-cresol......	61	27	32	30 „

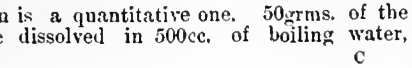
With *m*-cresol the following table is given. (Temperature of I. and II. 300—320°; III. 330—340°);—

	I.	II.	III.
m-Toluidine	29	27	25 per cent.
Di-*m*-tolylamine	53	51	47·5 „
Carbonaceous matter	2·5	4	5 „
Unchanged *m*-cresol	10·5	10	16 „

A quicker method for extracting the bases from the sealed tubes is to bring the product directly into a distilling flask and heat to 180—200° in ammoniacal steam. Primary and secondary bases, as well as the unchanged cresol, distil over.—J. B. C.

A New Method for the Preparation of the Azines. O. N. Witt. Ber. **20**, 571—577.

The author finds that certain azo derivatives of naphthylamine, obtained by the action of diazobenzene and diazotoluene-sulphonic acids on phenyl-, tolyl- and xylyl-β-naphthylamine, when heated with mineral acids, split up into the phenazine derivatives of naphthalene and the amido-sulphonic acid, phenyl-β-naphthylamineazobenzene sulphonic acid yields sulphanilic acid and naphthophenazine—$SO_3H.C_6H_4.N:N.C_{10}H_6.NH.C_6H_5$ ($SO_2H:N$ and $N:NH = 1:4$ and $1:2$)



$$= C_6H_4.NH_2.SO_3H + C_{16}H_6\left<\begin{matrix}N\\|\\N\end{matrix}\right>C_6H_4.$$

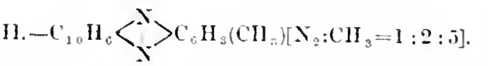
The reaction is a quantitative one. 50grms. of the azo-colour are dissolved in 500cc. of boiling water, and 125cc. of concentrated H_2SO_4 are added drop by drop and well shaken. The free acid at first separates as a tarry mass, but re-dissolves gradually, and the sulphate of the azo base crystallises from the orange coloured liquid in cinnabar-red needles. On boiling the product with water, the free azine is obtained in the form of white crystals (m.p. 142·5°). Naphthophenazine forms well crystallised salts with mineral acids, which are dimorphous.

The author thinks that the dimorphism is due to the existence of two different salts, and that both nitrogen atoms are pentavalent, and combine with acids. Concentrated HNO_3 forms a nitroderivative. In order to determine the constitution of naphthophenazine, the same compound was prepared from β-naphthoquinone and *o*-phenylenediamine, and by the oxidation of a mixture of *o*-phenylenediamine and β-naphthol. This new method for preparing azine compounds indicates in the first place that with suitable re-agents there is a strong tendency to form the azine group, so that it is produced even when the para position is free.—J. B. C.

On the Isomeric Tolunaphthazines and the Black Dye for Wool. O. N. Witt. Ber. **20**, 577–581.

ACCORDING to theory, two α-β-tolunaphthazines are possible with the formulæ I. and II.:—

$$\text{I.}—C_{10}H_6<\overset{N}{\underset{N}{|}}>C_6H_3(CH_3).[N_2:CH_3=1:2:4];$$



$$\text{II.}—C_{10}H_6<\overset{N}{\underset{N}{|}}>C_6H_3(CH_3)[N_2:CH_3=1:2:5].$$

The nitrogen atoms are situated in the 3 : 4 position as regards the naphthalene nucleus.

In order to determine the constitution of Hinsberg's tolunaphthazine obtained from toluylenediamine and β-naphthoquinone, the author prepared an azine compound from paratolyl-β-naphthylamine according to the method given in the previous abstract, and obtained a naphthazine differing in its properties from that of Hinsberg. By the action of mineral acids upon the black dye for wool, which is prepared by the action of diazo-azobenzenedisulphonic acid on paratolyl-β-naphthylamine, a tolunaphthazine is obtained, which is distinct from the other two. The author shows further that Hinsberg's compound is a molecular mixture of the two other isomeric tolunaphthazines. According to this, the compound prepared from paratolyl-β-naphthylamine has formula I. that from the black dye formula II.—J. B. C.

Acenaphthene. F. Quincke. Ber. **20**, 609–611.

THE author, by nitrating acenaphthene with concentrated HNO_3 in glacial acetic acid, obtained a mononitro derivative, which on reduction yields an amido-compound.—J. B. C.

β-α-Azonaphthalene. R. Nietzki and J. Göttig. Ber. **20**, 612–613.

β-α-AMIDOAZONAPHTHALENE is first obtained as follows: A solution of β-diazonaphthalene is prepared from 1mol. β-naphthylamine, 5mols. HCl, and 1mol. $NaNO_2$. As soon as the naphthylamine is dissolved, 1mol. α-naphthylamine hydrochloride dissolved in water is added. After 12 hours, β-α-amidoazonaphthalene separates out as the violet-brown hydrochloride. The corresponding azonaphthalene is obtained by dissolving 1 part of the amidoazo-compound in 50 parts of alcohol, to which 3 parts of concentrated H_2SO_4 are added. Then a sufficient quantity of a concentrated solution of $NaNO_2$ is added, until the violet colour of the liquid changes to a yellow-brown. The mass is boiled for a time, and in case the violet colour reappears, more nitrite is added. The crude azonaphthalene is precipitated with water, and crystallised from glacial acetic acid. It is a dark-brown crystalline body, with a steel blue lustre. It melts at 136°, much lower than the α-compounds (190°). It has the formula :—$C_{10}H_7\overset{\beta}{N}:\overset{\alpha}{N}.C_{10}H_7$.—J. B. C.

Derivatives of Diphenylethane. K. Heumann and J. Wiernik. Ber. **20**, 909–915.

THE authors point out that in order to produce a colouring matter, it is necessary, in the case of methane, that at least two amido-phenyl groups should be attached to the methane carbon atom. Diamidodibenzyl, prepared according to Fittig and Stelling's method, gives no colouring matter on oxidation, and is therefore not a leuco-base. Tetramethyldiamidodiphenylethane, contrary to Schoop's statement, gives no pure colouring matter on oxidation. It follows then that the introduction of two symmetrical methylamidophenyl groups into the ethane molecule gives, on oxidation, no colouring matter; whereas, in the case of methane, with two groups attached to the same carbon atom, colouring matters are produced. The same result is obtained if the amido group is replaced by hydroxyl—*i.e.*, if two phenol groups are introduced symmetrically into the ethane molecule. Wislicenus has shown that ethane containing three phenol groups, or triphenolethane $C_6H_4(OH).CH_2.CH:(C_6H_4OH)_2$, on oxidation gives a colour which dyes wool.—J. B. C.

Monomethylorange and Monoethylorange—their Conversion into Dimethyl- and Diethylthionin. A. Bernthsen and A. Goske. Ber. **20**, 924–934.

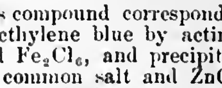
Monomethylorange is prepared as follows :—220grms. of sodium sulphanilate, 74grms. of $NaNO_2$, and 100grms. of concentrated H_2SO_4, in about 1½ litres of water, are mixed together. The resulting diazobenzene sulphonic acid is filtered and added to 80grms. of pure monomethylaniline, 80grms. of concentrated HCl and 300cc. of water, and heated to 30°. The mass becomes thick from separation of needles of the azo-acid. It is filtered and converted, by the addition of caustic soda, into the sodium salt, which crystallises in orange-red tablets. It may be distinguished from helianthin by its somewhat redder shade. The free azo-compound has the formula $C_6H_4(SO_3H).N_2.C_6H_4NH(CH_3)$, and consists of violet, needle-shaped crystals. The isomeric diazo-compound, $C_6H_4(SO_3H)N:N.N(CH_3)C_6H_5$, is often formed at the same time. It may be separated by treating the product with $(NH_4)_2S$, which decomposes the azo compound, but leaves the diazo-compound unaltered. With dilute acids it is converted into monomethylorange, while with strong HCl it is split up into methylaniline and *p*-phenolsulphonic acid.

Monoethylorange is obtained, though less rapidly, under the same conditions as described for methylorange. It is better to use the diazobenzene sulphonic acid in solution, and to neutralise the free acid formed by gradually adding NaOH so that the sodium salt separates out. This compound has the formula $C_6H_4(SO_3Na).N:N.C_6H_4NH(C_2H_6)$.

Monomethyl-p-phenylenediamine.—Methylorange is split up with warm $(NH_4)_2S$ into sulphanilic acid and methylphenylenediamine. The latter is extracted with ether, the base dissolved out with the calculated quantity of H_2SO_4 (1 : 4), which separates out, on digesting with alcohol, as a voluminous crystalline mass. Solutions of its salts are coloured deep red with Fe_2Cl_6 or Br. Acidified with HCl the solution is decolourised, but changes to blue on the addition of H_2S.

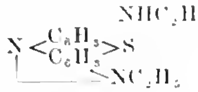
Monoethyl-p-phenylenediamine.—Ethylorange is decomposed with $(NH_4)_2S$ similarly to the methyl compound, ethylphenylenediamine being formed.

Dimethylthionin



—The production of this compound corresponds exactly to the formation of methylene blue by acting on the diamine with H_2S and Fe_2Cl_6, and precipitating the colouring matter with common salt and $ZnCl_2$. The hydrochloride dissolves readily in water with a blue colour and reddish-brown fluorescence. The neutral solution is precipitated by mineral acids. Like thionin, it exchanges one imido group for oxygen, and forms methylthionoline, and by further replacing the amido group by hydroxyl gives thionol.

Diethylthionin



$$N<\begin{matrix}C_6H_3\\C_6H_3\end{matrix}>S \quad NHC_2H_5 \quad NC_2H_5$$

—This body is formed in the same manner as the methyl compound, which it closely resembles in appearance and properties.—J. B. C.

Action of Carbonic Acid on Ultramarine Blue. Dr. E. Büchner. Chem. Zeit. 11, 314.

If carbonic acid is allowed to act on ultramarine blue suspended in water, a liberation of sulphuretted hydrogen takes place. If the reaction continue till the evolution of H_2S ceases, the water, frequently changed and decanted, is found to contain an appreciable amount of sodium carbonate. The explanation of this reaction is that the carbonic acid decomposes the Na_2S of the ultramarine blue. The presence of Na_2S, however, cannot be shown by the nitro-prusside test. If well-washed ultramarine be used, the same reaction takes place. The disengagement of H_2S also takes place if carbonic acid be led over dry lump ultramarine, and in larger quantity if the pieces are somewhat moistened. If ultramarine, treated as above, be dried and compared with the normal ultramarine, it is found that the blue has become quite dull and reddish, owing to the loss of Na_2S.

Prepared ultramarine blue shows similar reactions, but these are not so strongly marked.—J. F. C. S.

New Green Colouring Matter. W. Krause. Internat. Monatsschr. f. Anat. u. Physiol, 4, 2.

The zinc double salt of thiophen green (see page 505), tetramethyldiamidodiphenylthiënylcarbinol, is well adapted for staining sections, etc., especially as a complementary colour to carmine. It dissolves readily in water, alcohol and chloroform, but is insoluble in benzene.—C. A. K.

Indian Yellow and Glycuronic Acid. E. Külz. Zeit. für Biol. 33, 475—485.

Euxanthic acid is, according to Spiegel, decomposed by hydrochloric acid into glycuronic acid and euxanthone. The author, in order to prove the animal origin of euxanthic acid, gave euxanthone to rabbits and dogs, and was able to detect euxanthic acid in the urine. Like that obtained from *purree* (a combination of euxanthic acid and magnesia), it rotated polarised light to the left. While the experiments show that Indian yellow may be of animal origin, they in no way disprove that it may also be produced by the action of plants. The author's experiments did not corroborate Schmid's statement that mangostin (obtained from *Garcinia mangostana*) is similarly converted into euxanthic acid by animals.
—C. A. K.

Improvements in and relating to the Manufacture of Colouring Matters. H. H. Lake, London. From Wirth & Co., for A. Leonhardt & Co., Mühlheim, Germany. Eng. Pat. 4387, March 29, 1886. 6d.

Paranitrotoluene is sulphonated by being heated with one part of sulphuric acid (66° B.) and two parts of fuming acid containing 35 per cent. of anhydride. The heating is continued for 12—24 hours at 120° C., and the nitro-sulphonic acid treated with caustic soda and zinc dust, or, preferably, first with soda and then afterwards reduced in alkaline solution with zinc dust. The resulting compound is said not to be tolidinedisulphonic acid, but a "new amidosulpho-acid," which yields tetrazo-salts, from which secondary azo-colours can be prepared. A list of the amines, phenols, sulphonic and carboxylic acids is given in the specification, the three following examples being illustrative of the manufacture of the azo-colours:—(1.) The sodium salt of the new amidosulphonic acid is diazotised by sodium nitrite and hydrochloric acid in the usual way, and then combined with two molecules of β-naphthylaminemonosulphonic acid (Brönner's). The colour thus produced is a red dyestuff. (2.) A yellow colour is formed by the action of the tetrazo-salt upon salicylic acid in alkaline solution. (3.) A violet colour is produced by the action of the tetrazo-salt upon α-naphthol in alkaline solution.—R. M.

Improvements in the Production of Indole Derivatives from the Compounds of the Aromatic Hydrazines with the Ketones and Aldehydes. C. D. Abel, London. From the "Farbwerke vorm. Meister Lucius & Brüning," Hoechst a Main, Germany. Eng. Pat. 7137, May 27, 1886. 6d.

The process described in the present specification depends upon the formation of condensation products between primary or secondary hydrazines and ketones or aldehydes, and the treatment of these products with anhydrous acids or with metallic chlorides, by which means ammonia is withdrawn and the indole derivative synthetised. The following typical equations illustrate the method:—

$$C_6H_5.N_2H_3+CH_3.CO.CH_3=C_6H_5.N_2H{:}C(CH_3)_2+H_2O.$$

$$C_6H_5.N(CH_3).NH_2+CH_3.CO.CH_3=C_6H_5.N(CH_3).N{:}C(CH_3)_2+H_2O.$$

$$C_6H_5.N_2H_3+OCH.C_2H_5=C_6H_5.N_2H{:}CH.C_2H_5+H_2O.$$

Ammonia can be withdrawn from the condensation products by heating with sulphuric or hydrochloric acids, but the best results are obtained by the use of solid zinc chloride—

$$C_6H_5.N_2H{:}C(CH_3)_2=NH_3+C_6H_4<\begin{matrix}CH\\NH\end{matrix}>C.CH_3$$

(Methylketole.)

In the preceding case the condensation product is heated to 170—180° C. with 4—5 times its weight of solid zinc chloride, the reaction being complete in a few minutes and the yield of methylketole over 60 per cent. of the theoretical quantity. By a similar process acetonemethylphenylhydrazine yields dimethylindole—

$$C_6H_4<\begin{matrix}CH\\N(CH_3)\end{matrix}>C.CH_3$$

With propylidenephenylhydrazine the reaction sometimes sets in spontaneously with an equal weight of zinc chloride, the product being skatole. Aromatic derivatives are similarly obtained from the condensation products of hydrazines with aromatic ketones and aldehydes. Thus the following compounds are given as examples:—

(1.)

$$C_6H_4<\begin{matrix}CH\\NH\end{matrix}>C.C_6H_5$$

(Phenylindole from acetophenonephenylhydrazine.)

(2.)

$$C_6H_4<\begin{matrix}CH\\N(CH_3)\end{matrix}>C.C_6H_5$$

(Methylphenylindole from acetophenonemethylphenylhydrazine.)

(3.)

$$C_6H_4<\begin{matrix}C.(C_6H_5)\\NH\end{matrix}>C(C_6H_5)$$

(Diphenylindole from "de-oxybenzoinphenylhydrazine.")

(4.)

$$C_{10}H_6<\begin{matrix}CH\\NH\end{matrix}>C.CH_3$$

(Methyl-β-naphthyiindole from acetone-β-naphthylhydrazine.)

Examples are also given in which the carboxylic acids of aldehydes and ketones are first employed to form condensation products with the hydrazines. The indole derivatives, obtained according to the processes described in the specification, are intended to be employed for the preparation of colouring matters and as antiseptics.
—R. M.

Improvements in the Production of Green Colouring Matters or Dyestuffs. C. D. Abel, London. From the "Farbwerke vorm. Meister Lucius & Brüning," Hoechst a/Main, Germany. Eng. Pat. 8992, July 9, 1886. 4d.

These colouring matters are prepared by the action of nitrous acid upon an acid solution of methylene or ethylene blue or other alkyl thionines. The solution of the colouring matter in water is acidified by sulphuric acid and sodium nitrite (eight parts to ten of methylene blue) added by degrees. The mixture is allowed to stand for several days and the green colouring matter salted out. The mother-liquor contains a compound which is precipitated by zinc chloride and reduced again to methylene blue.—R. M.

Improvements relating to Substances chiefly designed for use in the Preparation of Colouring Matters, and to the Manufacture of Colouring Matters therefrom. A. Kern, Basle, Switzerland. Eng. Pat. 12,022, Sept. 21, 1886. 6d.

The reagent employed by the author is carbon sulphodichloride $CSCl_2$. The compounds obtained are derivatives of thiobenzoic acid and thiobenzophenone, and are classified as follows:—(1.) Alkylised amido derivatives of the chloride of thiobenzoic acid and derivatives of this acid by the action of the reagent upon tertiary aromatic amines. (2.) Alkylised amido derivatives of thiobenzophenone by the action of alkylised amido derivatives of the chloride of thiobenzoic acid or by the direct action of the reagent upon tertiary aromatic amines. (3.) The formation of colouring matters by the condensation of the new compounds produced in the two preceding groups with amido-compounds or phenols. (4.) The formation of colouring matters by the action of the reagent upon tertiary aromatic amines. Seven examples illustrative of the manufacturing processes are given:—(1.) Dimethylaniline diluted with CS_2 and cooled to 0° C. is gradually mixed with the necessary quantity of the reagent, also diluted with CS_2. The product is dimethylamidothiobenzoic acid, $C_6H_4.CSOH.N(CH_3)_2$. (2.) By using the above materials in the correct proportions, and finishing the reaction at 35° C., tetramethyldiamidothiobenzophenone is produced. (3.) A yellow colouring matter is prepared by passing ammonia gas into a solution of tetramethyldiamidothiobenzophenone in naphthalene at 150° C. (4.) An orange colouring matter is formed by heating the thiophenone with aniline as long as SH_2 is evolved. (5.) To prepare a blue colouring matter the thiophenone is heated with phenyl-α-naphthylamine, toluene and carbon sulphodichloride. (6.) A violet colouring matter is obtained by mixing the thiophenone with dimethylaniline and the reagent. The reaction is completed at 100° C. (7.) The violet dye can be prepared directly by the action of carbon sulphodichloride upon dimethylaniline in the presence of dry zinc chloride at 25—30° C., and finishing at 100° C. as in the last example.—R. M.

VI.—DYEING, CALICO PRINTING, PAPER STAINING AND BLEACHING.

A Process of Treating Woven and other Fabrics, Yarns, Ropes and Cordage for the Purpose of rendering the same Non-Putrefactive and Antiseptic. A. M. Clark, London. From L. P. Audouard, France. Eng. Pat. 7927, June 12, 1886. 6d.

The method consists in exposing the materials to wood smoke.—E. J. B.

Improvements in Dyeing Blue, especially adapted for Wool. C. Lohmann, Cologne, Prussia. Eng. Pat. 8065, June 17, 1886. 4d.

This invention consists in dyeing wool or other animal fibrous materials in a bath containing azo-diphenyl blue, extract of logwood, sulphate of copper, sulphate of iron, an alkaline bisulphate and oxalic acid.—E. J. B.

Improvements in Dyeing Tissue and other Papers, and in Apparatus therefor. J. Fletcher, Stoneclough. Eng. Pat. 13,598, Oct. 25, 1886. 6d. (Amended Specification.)

The amendment consists in the deletion of the third claim—viz., "the endless felt or cloth for supporting the dyed paper in its wet state and carrying it through the machine." (See this Journal, 1887, 139.)—H. A. R.

Improvements relating to the Drying, Bleaching and Disinfecting of Wool, Cotton, Paper Pulp or other Textile or Fibrous Materials and to Apparatus therefor. J. H. Lorimer, Philadelphia, U.S.A. Eng. Pat. 16,765, Dec. 21, 1886. 8d.

The operation is conducted in a chamber of special construction, and the bleaching or disinfecting compound (bleaching liquor, sulphurous acid, etc.) is applied in the form of a fine spray. The drying is effected in the same chamber.—E. J. B.

Improvements relating to the Treatment of Wool, Cotton, Paper Pulp or other Textile or Fibrous Materials for effecting the Bleaching, Colouring, Disinfecting and Drying or other Operations, and to Apparatus therefor. J. H. Lorimer, Philadelphia, U.S.A. Eng. Pat. 16,780, Dec. 21, 1886. 8d.

This patent relates to certain slight improvements in the apparatus described in Eng. Pat. 16,765.—E. J. B.

An Improved Compound for producing Designs upon Textile Fabrics and for similar Purposes. H. H. Lake, London. From L. Whitefield, Reading, Mass., U.S.A. Eng. Pat. 2123, Feb. 10, 1887. 4d.

The improved compound consists of a mixture of benzene, naphtha or turpentine and a suitable pigment of any desired colour, such, for example, as chrome yellow or Chinese blue, with a little bronze powder and kerosene oil. It is used for transferring patterns to fabrics, the former being perforated and acting as a stencil.—E. J. B.

Improvements in Apparatus for Dyeing Loose or Spun Cotton and other Fibres. E. Booth, Manchester. From W. A. Fourness, Brussels, Belgium. Eng. Pat. 4365, March 23, 1887. 6d.

The apparatus consists of a strong copper or iron vessel, which can be hermetically sealed. It is in connection with an arrangement for producing a vacuum. The inventor claims the use of the vessel for the purpose of dyeing materials with any other colour but black, a similar apparatus having been previously patented for dyeing that colour.—E. J. B.

An Improved Mode of and Apparatus for Mordanting, Dyeing and Bleaching Raw Cotton. G. Jagenburg, Rydboholm, Sweden. Eng. Pat. 4764, March 30, 1887. 8d.

The inventor conducts the operations, usually bleaching, dyeing and mordanting operations, either in the cold or at low temperatures in vacuo. Drawings of the necessary apparatus are given in the specification.—E. J. B.

VII.—ACIDS, ALKALIS AND SALTS.

On the Determination of some High-melting and Decomposition Temperatures. H. Le Chatelier. Bull. Soc. Chim. **47**, 300.

In his investigations the author made use of the electric pyrometer described by him, which permits of the quick and exact determination of high temperatures. The following melting points were ascertained:—KCl 740°, NaCl 775°, $CaCl_2$ 755°, $BaCl_2$ 847°, $SnCl_2$ 840°, Na_2CO_3 810°, $BaCO_3$ 795°, K_2CO_3 885°, Na_2SO_4 867°, $Ba(NO_3)_2$ 592°, K_2SO_4 1015°, $K_2Cr_2O_4$ 975°, $Na_4P_2O_7$ 957°, $KClO_3$ 37°0, Cu_2S 1100°, very pure white pig-iron 1135°, grey cast-iron 1240°, nickel 1420°. The temperatures of decomposition of the following salts were ascertained:—$MgCO_3$ 680°, $CaCO_3$ 890°, $FeSO_4$ 700°, $MnSO_4$ 990°, $MgSO_4$ 1160°. The oxides of Al, Cr, and Fe, as is commonly known, by gradual heating are subjected to a change which is accompanied by a considerable production of heat, and in consequence of which they become insoluble in acids. These precise temperatures are:—Al_2O_3 850°, Cr_2O_3 900°, Fe_2O_3 950°. The method of observation followed consisted in placing the salt to be studied in a little platinum cone 5mm. in diameter, and covering it with an envelope of magnesia and refractory earth. The whole was heated in a Forquignon's furnace, which was fed by a blast pipe. This arrangement was for the purpose of assuring as complete a uniformity of temperature as possible throughout the mass of the salt experimented on. The progress of heating of the thermocouple placed in the middle of the salt was registered by the photographic method by means of induction sparks, which passed from second to second. At the moment of fusion there was a momentary arrest in the heating, which manifested itself in the approach and superposition of the images of the slit in front of which the spark played.—W. R.

A New Hydrate of Caustic Soda. C. Göltig. Ber. **20**, 543—544.

On carefully heating a concentrated solution of caustic soda in strong alcohol a slow separation of fine crystals occurs, the amount of which, on continued heating, increases. These crystals, which disappear on cooling the alcoholic solution, are very unstable and difficult to isolate. If the alcoholic solution is further heated the crystals redissolve, but after a time, as the alcohol evaporates, aggregated masses of crystals appear, which have the formula $NaOH + 2H_2O$. This compound is not very hygroscopic, but readily absorbs CO_2 from the air. Part of the water of crystallisation evaporates over $CaCl_2$ in a desiccator.—J. B. C.

General Method for the Preparation of Manganites from Permanganates. G. Rousseau. Compt. Rend. **104**, 785.

Potassium permanganate heated to 240° yields potassium manganate, manganese dioxide and oxygen, but if the heating be continued the dioxide disappears and manganites are formed, and these the more readily the higher the temperature. A pentamanganite $K_2Mn_5O_{11}$, and a heptamanganite $K_2Mn_7O_{15}$ are obtained. The latter is also formed when potassium permanganate is heated to 800° in a bath of potassium chloride. The author suggests that the formation of manganites is due to the action of the manganese dioxide on the manganate formed, whereby a further liberation of manganese dioxide takes place, and this combines with free alkali present, forming a manganite:—$MnO_2 + 3K_2MnO_4 = 2KMnO_4 + 2MnO_2 + 2K_2O$. This action accounts for the loss experienced in preparing potassium manganate from the permanganate when too high a temperature is employed. The permanganates of barium and strontium also yield polymanganites on heating to 350°, while calcium permanganate behaves similarly at 200°.
—C. A. K.

Antimony Tartrate. Guntz. Compt. Rend. **104**, 850.

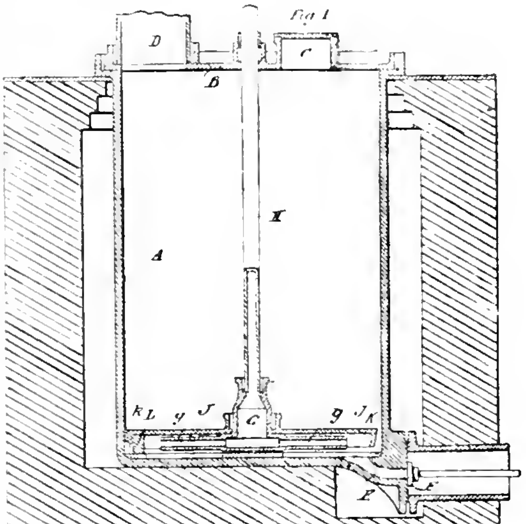
Peligot's method for obtaining acid antimony tartrate by precipitating a solution of antimony oxide in tartaric acid with alcohol, yields an amorphous product which contains varying amounts of antimony, according to the method of precipitation. The acid antimony tartrate ($C_4H_5O_6.SbO$) may be obtained in a pure state by boiling a solution of tartaric acid with an excess of antimony oxide for several hours and concentrating the solution obtained on the water-bath, when a crystalline precipitate is obtained, which is purified by washing with absolute alcohol.—C. A. K.

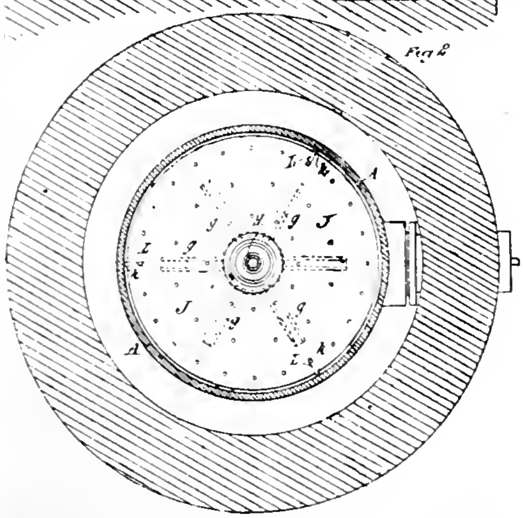
An Improved Apparatus for the Manufacture or Production of Carbonic Acid and other Gases. P. Farinaux Lille, France. Eng. Pat. 8312, June 23, 1886. 8d.

This invention relates to an apparatus for regularly producing, in proportion as they are consumed, carbonic acid or other gases resulting from chemical decomposition. The apparatus also discharges the gases at a constant pressure. The gas liberated by the action of an acid on the solid material passes through a purifier and subsequently leaves the apparatus through a loaded valve.—S. H.

Improvements in Apparatus for Producing Ammonia from Sulphate of Ammonia. H. W. Deacon and F. Hurter, Widnes. Eng. Pat. 9208, July 15, 1886. 8d.

This invention relates to apparatus for carrying out th,' process described in Eng. Pat. 2118, 1884 (this Journa 1885, 281), which consists in heating to a high temperature in an atmosphere of steam, a mixture of ammonium and sodium sulphates. A cylindrical cast-iron pot A (Figs. 1 and 2) is provided with a closely-fitting lid B, having a charging hole C and an outlet pipe D for the escape of gaseous ammonia and steam. An aperture E, closed by a plug F near the bottom, allows of the withdrawal of the contents when the operation is completed. Close to the bottom there is a small central chamber G provided with a number of radiating pipes g which serve for the distribution of superheated steam supplied thereto by the pipe H. Immediately over the pipes g a false





bottom J is placed, the perforations of which distribute the steam equally throughout the charge. The false bottom J, which is of less diameter than the pot A, is also fitted with a downward flange K having several projections L by which it rests on the bottom of the pot. The false bottom thus forms a shallow vessel surrounding the steam chamber. When the charge is first introduced it blocks up the perforations of the false bottom, and the steam is therefore compelled to pass through the annular space between the flange and the interior of the pot, at which part it is first required, as the charge first fuses at these places. Gradually the fusion proceeds through the whole mass, freeing the perforations and allowing the steam to issue through the false bottom, as the liquid formed lutes the space at the circumference near the flange. The pot is set in brickwork and provided with a fireplace and flues, so that it may be heated from the outside.—S. H.

New or Improved Process for the Simultaneous Manufacture of Assimilable Phosphates and of Sulphate of Ammonia. E. Solvay, Brussels, Belgium. Eng. Pat. 8723, July 3, 1886. 6d.

If phosphate of lime be treated with sulphuric acid, almost insoluble calcium sulphate and soluble monobasic calcium phosphate are produced. The object of this invention is to economise a portion of the acid employed by combining the manufacture of superphosphates with that of ammoniacal salts. Ammonia is allowed to act on monobasic calcium phosphate, thereby forming dibasic calcium phosphate and ammonium phosphate, both of which have a high agricultural value. If it be preferred to obtain all the phosphoric acid as ammonium phosphate, the dibasic calcium phosphate is treated over again with sulphuric acid. Even more ammonia may be fixed in the finished article, as calcium sulphate effects double decomposition with ammonium carbonate, yielding ammonium sulphate and calcium carbonate.

—S. H.

VIII.—GLASS, POTTERY AND EARTHENWARE.

An Improved Potter's Filter-press. J. Critchlow, T. Forrester, W. Forrester, H. Forrester and L. Forrester, Hanton. Eng. Pat. 1941, Feb. 8, 1887. 8d.

The filtering cloths usually employed are replaced by porous drainage tiles fixed on the surfaces of the ribbed or corrugated plates.—C. C. H.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

An Improved Compound for Plastering and for Preventing the Radiation and Transmission of Heat. R. W. Hitchins, Stoke Newington. Eng. Pat. 6804, May 20, 1886. 6d.

About equal proportions of slag-wool and plaster of Paris or cement in a dry state are mixed intimately together. The product obtained is lighter than ordinary plaster, more porous and capable of resisting a greater amount of heat.—E. G. C.

Treatment of Slate, Schist and Waste thereof for the Production of Material applicable for Structures, Vessels and other Uses. J. B. F. Frédureau, Paris. Eng. Pat. 7285, May 31, 1886. 6d.

Powdered schist or slate is made up into a paste with a solution of silicate of potash or of soda, the paste is moulded into the desired forms, and the moulded pieces are dried, preferably with the aid of a little heat. The material so made ("Ardoisite") is at once applicable for structural purposes, or for making tanks, vessels, pipes, etc.; it is readily worked by saws, planes or other tools, and is especially useful in laboratories and chemical works, as it is not subject to corrosion by acids. If impregnated with paraffin, tar, petroleum, etc., the material can be used as an electrical insulator. If dried "ardoisite" be gradually heated up to a white heat, it is brought into the condition of a refractory stone of great durability, particularly applicable for furnaces or furnace vessels.—E. G. C.

Improvements in the Manufacture of Portland Cement. S. Lowden, London. Eng. Pat. 8120, June 18, 1886. 6d.

The inventor manufactures what may be termed the "nucleus" of the cement, by thoroughly mixing, drying and kilning one part by weight of Medway blue clay, in its natural state, and five parts of chalk or limestone. The material so prepared is fit for transport to any part where chalk or limestone abounds and where the finished product is intended to be employed. To complete the manufacture, chalk or limestone is pulverised, dried at about 210° F. and mixed with the prepared "nucleus" in the proportion of one part by weight of the chalk or limestone to three parts of the "nucleus"—an excellent Portland cement being thus obtained.

—E. G. C.

Method of and Apparatus for Desiccating Wood and other Porous Substances. A. Flamache and E. Picard, Brussels, Belgium. Eng. Pat. 10,595, Aug. 1886. 8d.

The object of the patentees is to effect the desiccation of wood simultaneously throughout the whole mass, instead of its commencement at the exterior and its gradual progress inwards. They effect this by placing the material in an air-tight vessel, in which a partial vacuum is formed, the air thus expelled from the pores of the wood carrying with it moisture; this is followed by the admission of dry atmospheric air either heated or cooled, which takes up a further quantity of moisture and is again expelled as before. In some cases, instead of a reduction of pressure below that of the atmosphere, air at atmospheric pressure and compressed air alternately operate; the effect is practically the same. Hot air may be employed and the interior of the vessel heated, dependent upon the nature of the material operated on.

—C. C. H.

Improvements in the Manufacture of Building Materials from Glass and in the Application of the same. S. Pitt, Sutton, Surrey. From G. Falconnier, Nyon, Switzerland. Eng. Pat. 5723, April 19, 1887. 6d.

The patentee claims the employment of bricks formed from blown glass of various shapes and secured in the manner shown in the drawing attached to the specification, for use in building. Such hollow bricks may be employed in almost every instance in which ordinary bricks or tiles are used. The interior of the glass brick may be decorated or painted with any devices.

—C. C. H.

A Novel Artificial Cement. W. E. Gedge, London. From J. Thorrand, V. Nicolet and A. Bonnet, Grenoble, France. Eng. Pat. 979, Jan. 21, 1887. 4d.

This cement consists of "an intimate mixture, in contact with water, of dried and pulverised chloride of magnesium, with or without the addition of inert matters or calcareous powder, with magnesia also pulverised and mixed with calcareous powder or inert matters." This product is white like plaster and is capable of receiving various tints by the addition of coloured earths.

—E. G. C.

X.—METALLURGY, Etc.

On Certain Metals. V. Meyer. Ber. **20**, 497—500.

The Melting Point of Magnesium is usually given in the text-books as about 500° C. Experiments have shown that the melting point lies above that of sodium bromide (700°), and just below that of sodium carbonate (800°).

The Purification of Mercury may be very readily performed by repeated distillation. All impurities are left behind in the retort. After twelve successive distillations the author found that no residue remained on heating, and that the metal was chemically pure. A quicker method is that usually adopted—viz., recrystallisation of mercurous nitrite.

Volatility of Germanium.—The author finds that germanium does not volatilise sensibly when heated to 1350° C. in an atmosphere of hydrogen or nitrogen. This agrees with Nilson and Petterson's observations, who heated germanium to 1300° with a similar result. The author attempted, without success, to determine the vapour density of magnesium. He intends shortly to determine that of antimony.—J. B. C.

An Improved Manufacture of Alloy or Alloys of Nickel, Copper and Aluminium. J. Y. Johnson, London. From La Société Anonyme Le Ferro-Nickel, Paris, France. Eng. Pat. 5832, April 29, 1886. 6d.

To the melted nickel the charge of copper is stirred in, and subsequently, at a somewhat higher temperature, a proportion of aluminium varying, according to the percentage of nickel, from 1·75 of aluminium per 1000 of the mixture in the case of an alloy with 10 per cent. of nickel, down to 0·5 of aluminium per 1000 for one with 40 per cent. of that metal. The fused mass is then raised almost to its boiling point, and poured rapidly and regularly. Malleable nickel may in part be substituted for aluminium but with less satisfactory result.

—W. G. M.

Improvements relating to the Extraction or Separation of Gold, Silver and Platinum from Ores and other Substances or Products containing such Metals. J. Noad, East Ham. Eng. Pat. 6810, May 10, 1886. 6d.

See page 516.

Process and Apparatus for the Treatment of Iron Ores for the Manufacture of Steel. A. M. Clark, London. From La Société Anonyme des Produits Chimiques de St. Denis, France. Eng. Pat. 6747, May 19, 1886. 8d.

This is a process for treating iron oxides in pulverulent condition, and is especially applicable to the spent pyrites of the vitriol maker. The reduction is effected in an upright furnace with nine or more superposed hearths. Running axially through the furnace is a vertical water-cooled rotating shaft, carrying rakes for stirring the ore on each hearth. The ore is fed on to the uppermost hearth and is gradually discharged (by the action of the rake) through channels in the bed, sloping inwards so as to deliver the ore into the centre of the next; thence it passes to the next hearth, in a like manner, and is then conducted to the next and so on, until it is finally discharged directly on to the bed of a regenerative melting furnace. Since the complete removal of sulphur previous to reduction is essential to success, the charcoal is not added to the charge at first, but is introduced at about the sixth stage. Moreover the atmosphere, which is of a reducing character on the lower hearths, is rendered oxidising in the upper portion in order to roast the ore more fully; this is accomplished by passing into the lowest hearth, producer gas which is thence led upwards by channels in the walls in a zig-zag direction over the higher stages until, nearer to the top, an excess of air from the regenerator of the melting furnace is mixed with it, the gases ultimately passing into a dust chamber. The pyrophoric iron dust falls into a space on the hearth of the melting furnace, where it is protected from oxidation by an inner perforated wall of refractory material. The furnace is heated by gas, which passes direct from a producer and mingles in a combustion chamber with the air from the regenerator and thence, before entering the furnace, passes over a screen of charcoal lumps to guard effectually against the presence of free oxygen or carbonic acid. When copper is present, the removal of the sulphur must be effected in a separate chamber; the residue being then freed from copper by extraction with acid and by subsequent washing, is reduced and melted as described.

—W. G. M.

Improvements in the Method of and Apparatus employed in Galvanising (Coating with Spelter) Sheet Metal. J. Thomas, Bradley; H. Lewis, Handsworth; and E. W. Lewis, Compton. Eng. Pat. 6786, May 20, 1886. 8d.

To obviate the necessity of straightening the galvanised plates, which are usually delivered from the rollers more or less curved, and to ensure uniformity of coating on both sides of the sheet, they are brought out from the zinc bath in a vertical position. The trough is rectangular in shape and has, working within it, two pairs of horizontal rollers geared outside the trough, one pair being placed immediately above the other with the upper pair at a slight distance beneath the surface of the molten metal. In the same horizontal plane with the lower pair is a third roller taking its motion only by contact with that which is next to it. Through a flux-box the plate to be coated is pressed between the loose roller and the adjacent roller of the lower pair, and by the motion of the latter is drawn down to a cradle beneath where, kept in position by a series of fingers, it is brought by means of a lever beneath the two geared rollers, and through them is carried upwards and finally delivered above.—W. G. M.

An Improved Process for the Separation of Metallic Tin from Tinned Plates or from Alloys or Salts of Tin. E. Edwards, London. From M. Ramos-Garcia, Paris, France. Eng. Pat. 6803, May 20, 1886. 6d.

If tinned iron be the substance treated, it must be stripped by agitation in a bath of hydrochloric acid with a small proportion of nitric acid or of ferric chloride and heated by steam. From the solution of the tin salt obtained the metal is precipitated on tin cathodes by galvanic batteries.—W. G. M.

Manufacture of Ferro-manganese, Silico-spiegel, Spiegeleisen and Chrome Iron. C. J. Sandahl, Trimsaran, South Wales; G. Bargate, Barrow-in-Furness; and C. B. Phillips, Chester. Eng. Pat. 6977, May 25, 1886. 6d.

In order to avoid the great loss of manganese or chromium owing to the large amount of slag formed in the manufacture of the above alloys, pig or scrap iron is substituted for iron ore in the furnace charge, so that the quantity of slag is much reduced. The charge, therefore, consists of broken pig or scrap-iron, fuel, manganese (or chrome) ores and the flux necessary for them.—W. G. M.

Improvements relating to the Extraction of Gold, Silver and Copper from Ores and other Substances or Products containing such Metals. J. Noad, East Ham. Eng. Pat. 8130, June 18, 1886. 6d.

The ore in a finely divided condition is allowed to remain in contact for 24 hours and afterwards roasted at a blood-red heat with a mixture of sodium chloride and sulphuric acid. The product is then ground and washed. The insoluble lead and silver chlorides are placed in a depositing tank with a suitable solution and electrolysed. The solution in the case of silver would be saturated with potassium cyanide containing ammonium carbonate and boric acid; for gold it would be ferrous sulphate; and for copper, cupric sulphate. The bath, after precipitation, is again available for the same purpose.—W. G. M.

Improvements in and connected with Refractory Linings particularly adapted for Metallurgical Furnaces, but applicable also for other Purposes. T. Twynam, London. Eng. Pat. 8359, June 24, 1886. 6d.

To render chrome-lining less susceptible of mechanical abrasion the chrome-iron ore, which must not be too silicious, is mixed with from 1 to 5 per cent. of an alkaline salt according as it will be required to withstand an intense or only a moderately high temperature. The salt should be dissolved in just sufficient water to

thoroughly moisten the ore, and the mixture may then be used directly as a lining, or it may be moulded into bricks, tuyères or the like, and be well burnt before use.
—W. G. M.

Improvements in Apparatus used for Coating Sheet Iron with Zinc or Alloys of Zinc or other Coating Metal or Alloy. R. Heathfield, Birmingham. Eng. Pat. 8390, June 25, 1886. 8d.

FROM the horizontal rolls of the galvaniser's bath, or by preference from the additional half-immersed rolls described in Eng. Pat. 2243, of 1877, the coated plate is passed between a pair of revolving brushes and finally through a pair of finishing rolls placed above the bath. The brushes are slightly longer than the length or breadth of the plate under treatment and may have a slight reciprocating motion in addition to rotation; the distance between them may also be regulated by suitable mechanism.—W. G. M.

Improvements in and connected with the Manufacture of Aluminium, and other Light Metals. F. J. Leaver, London. From Dr. E. C. Kleiner-Fiertz, Zurich, Switzerland. Eng. Pat. 8531, June 29, 1886. 8d.

SEE page 517.

Improvements relating to the Production of Aluminium and Alloys thereof. L. Grabau, Hanover, Germany. Eng. Pat. 9486, July 22, 1886. 6d.

IN order to economise the sodium or potassium, which is to a large extent volatilised when used for the reduction of aluminium chloride, and to prevent contamination of the reduced metal by contact with the walls of the heating vessel, the reduction is effected in a carbon crucible contained within a hermetically-closed chamber. The crucible, if small, is fashioned in one piece, or if large may be built up of carbon blocks cemented by tar; the cover is also lined with carbon and is joined by a magnesia lute, which is not attacked, at the temperature employed, by the alkali metal. The whole arrangement is heated to dull redness; when partial volatilisation of the sodium occurs, a most intimate mixture is produced, reduction commences attended by a copious evolution of heat and the reaction is finally completed with practically the theoretical quantity of sodium. The finely-divided aluminium is fused together with suitable flux in carbon crucibles. If alloys are required they may be made by mixing the alloying metal with the original charge or by introducing it during the subsequent fusion; or they may be made by forming the reducing crucible of the alloy metal, and melting together both crucible and contents with the requisite fluxes.—W. G. M.

Improvements in the Treatment of Ores containing Sulphide of Antimony for the Purpose of obtaining the said Sulphide in a Concentrated Form with any Gold or Silver that may be present. E. W. Parnell, Chester; and J. Simpson, Liverpool. Eng. Pat. 9919, August 3, 1886. 6d.

THE object of this invention is the concentration of sulphide of antimony in poor sulphide ores. It is effected by treating the finely-divided ore with a solution of sodium monosulphide, by which means the antimony becomes converted into a light red sulphide which remains for the most part in suspension in the sodium sulphide solution, the latter being practically unaltered. This solution is drawn off from the heavier gangue and the suspended sulphide allowed to settle, the solution being then available for treating a further quantity of raw ore. The gangue, from which the liquid has been drawn off, is washed free from any red sulphide intermixed with it and is available for the extraction of any gold and silver it may contain. Or it may be treated according to Eng. Pats. 11,828 and 13,074 of 1884 (this Journal, 1885, 352).—W. G. M.

Improvements in Linings of Copper, Lead and other Similar Furnaces, as well as Steel or Siemens Furnaces and Steel Converters. A. E. Tucker, Smethwick. Eng. Pat. 11,600, Sept. 13, 1886. 4d.

IN carrying out Eng. Pats. 7571 and 14,507 of 1885 (this Journal, 1886, 329), the inventor finds that basic slag, whether from the converter (by preference) or from the open hearth furnace, may be advantageously used either in the form of bricks for the sides and bottom, or by ramming for the latter. Cast slag bricks are made by melting the slag in a cupola or furnace with basic or neutral lining.—W. G. M.

Improvements in the Method of and Apparatus for the Smelting or Refining of Copper. D. McKechnie, St. Helens. Eng. Pat. 12,053, Sept. 22, 1886. 8d.

THROUGH the sides of a reverberatory (copper) furnace, a series of steam injectors cause a current of air and steam—if necessary mixed with powdered nitre—to be blown into or over the molten matter on the hearth, thereby greatly facilitating the removal of foreign substances from the metal.—W. G. M.

Improvements in Extracting Gold and other Precious Metals from their Ores, and Apparatus therefor. C. D. Abel, London. From E. Fischer and M. W. Weber, Berlin, Germany. Eng. Pat. 921, Jan. 20, 1887. 8d.

THE finely-crushed ore is charged together with six or eight times its volume of water and if necessary, sodium chloride or other chlorine or bromine compound and potassium permanganate, into a vat, the sides of which are partially lined with an amalgamated metal, and the bottom covered with mercury, both being connected with the negative pole of an electric generator. Here it is agitated for 2—2½ hours by a stirring apparatus, with shovels of amalgamated metal connected with the positive pole of the generator, which is maintained in operation for the whole period. When, by the action of the chlorides, the precious metals have been rendered soluble and have been deposited by the current, and taken up by the mercury, the whole charge is drawn off by a cock and run into an iron trough, in which a series of grooved wooden rollers, carrying carbons in the grooves as anodes, rotate at different speeds above the mercury, which is made the cathode, and retains any amalgam particles remaining in the water and sand. The tailings are discharged by means of india-rubber plates attached radially to the last roller.
—W. G. M.

An Improved Process for the Extraction of Gold, Silver, and other Metals from Ferriferous Ores containing the same. M. Constable and J. R. Bingle, Sydney, N.S.W. Eng. Pat. 2740, Feb. 22, 1887. 4d.

THE ore is wet crushed, if necessary first roasted, the mud treated with sulphuric acid and boiled; metallic iron or zinc is added to commence the reaction and the heating prolonged until solution of iron compounds is complete. The residue contains the precious metals, which may be extracted by any known method. The solution is evaporated and roasted, the acid vapours evolved being used to treat a fresh portion of raw material; the residue from this calcination consists of valuable oxides.—W. G. M.

Improvements in the Construction and Manufacture of Zincs for Galvanic Batteries. W. E. Heys, Manchester. From J. Beattie, jun., Westport, Mass., U.S.A. Eng. Pat. 4571, March 28, 1887. 4d.

SEE page 519.

Process for Extracting Aluminium from Alumina. D. G. Reillon and S. C. Montagne, Nantes; and O. L. B. L. Bourgerel, Paris, France. Eng. Pat. 4576, March 28, 1887. 4d.

ALUMINIUM sulphide is obtained by mixing alumina into a paste with tar or with charcoal (40 per cent.) and oil, heating the mixture to a red heat in a closed vessel and treating with carbon bisulphide vapour thus :—

$$2Al_2O_3 + 3C + 3CS_2 = 2Al_2S_3 + 6CO.$$

The sulphide is then heated in a current of a gaseous hydrocarbon, whereby the sulphur is removed and pure aluminium is left.—W. G. M.

Improvements relating to the Galvanising or Tinning of Wire Cloth, Wire Netting, or other Articles or Materials, and to Apparatus therefor. H. H. Lake, London. From C. Swinscoe, Clinton, U.S.A. Eng. Pat. 6042, April 25, 1887. 8d.

INSTEAD of using sand or asbestos as a scrubber, after the metal to be tinned has passed through the bath of molten metal, the inventor uses a layer of coke placed upon the surface of the bath.—B. T.

XII.—PAINTS, VARNISHES AND RESINS.

Improvements in Anti-fouling Compositions for Ships. J. Cameron, Renfrew. Eng. Pat. 7497, June 4, 1886. 4d.

CARBOLATES of mercury, copper, iron or zinc, alone or mixed with one another or with the carbolate of an alkaline earth, such as carbolate of barium, are combined with the ordinary dry pigment or material used in forming the paint or composition for coating ships' bottoms. —E. G. C.

Improvements in Gutta-percha Compounds and in the Manufacture thereof. R. Dick, Glasgow. Eng. Pat. 7524, June 4, 1886. 8d.

THE principal constituents used in the manufacture of these compounds are the several kinds of gutta-percha, or "crumb"—ground good old vulcanised indiarubber—ground veneer dust, sulphur, zinc oxide, French chalk, flocking, or the cut fibre of cotton textile fabrics, and ground alum.—E. G. C.

Improvements in the Process for preserving Iron and Steel Structures from Oxidation. W. Briggs, Arbroath. Eng. Pat. 7777, June 10, 1886. 4d.

THE surface to be preserved is first cleansed and then coated with a varnish composed of about 11lb. of coal-tar pitch, 4lb. of tar oil and 8½lb. of coal-tar naphtha. Before the varnish is quite dry, a coating of coal-tar pitch is applied with a brush.—E. G. C.

Improvements in the Manufacture of Pigments. J. M. Bennett, Ruchill, N.B. Eng. Pat. 8725, July 3, 1886. 8d.

IN place of crushing or grinding the pigments in pan mills, burr mills, edge runners, or the like, the inventor adopts a process which consists in breaking, disintegrating or compacting; the particles of the substances being treated in the dry state by a series of sudden impacts or shocks, in one or a series of breakers, disintegrators or compacters, enclosed within a chamber or chambers through which currents of dried or heated air may be passed.—E. G. C.

An Improved Process for Preparing a Metallic Covering for giving a Non-oxidising or only slightly oxidising Coating to Wood and other Materials or Objects. E. Schröder and H. Perner, Berlin, Germany. Eng. Pat. 10,127. August 7, 1886. 6d.

FOILS of any required shape and of extreme tenuity are made by depositing electrolytically a thin metallic coat upon a slightly varnished metal or other electrode of suitable form, from which they may be withdrawn, alone or strengthened by a backing material, and may then be glued upon the wood or object to be decorated. —W. G. M.

A Process for Preserving the Surface of Copper or its Alloys. E. de Pass, London. From La Société Industrielle et Commerciale des Metaux, Paris. Eng. Pat. 16,935, Dec. 24, 1886. 6d.

THE copper or brass to be protected is coated with cuprous sulpho-cyanate or cyanate, or rhodanide, either by dipping it into an ammoniacal solution of the salt, by electrolytic means, by incorporating the dried salt with lacquer or varnish, or by any other suitable method. —W. G. M.

A Novel Transparent Protective Enamel or Varnish. F. Garton, London. Eng. Pat. 3794, March 12, 1887. 4d.

THIS enamel is produced by the incorporation of the following ingredients :—10 parts of transparent "grains" mastic (*Pistacia Lentiscus*), seven parts camphor, 16 parts sandarach, 5 parts genuine elemi, together with Canada balsam and spirits of turpentine in equal parts. The whole is dissolved in alcohol, filtered and kept in a closed vessel until required for use.—E. G. C.

Improvements in the Preparation of Pigments, and in the Manufacture and Treatment of By-Products therefrom. T. Kenyon, Manchester. Eng. Pat. 4334, March 23, 1887. 4d.

THE inventor claims "(1.) The oxidation of iron and other impurities in zinc solutions (either containing ammonia salts or not) by means of air blown through the said solutions, either with or without steam at the ordinary pressure, or in closed boilers, which can be submitted to greater pressure. (2.) The precipitation of sulphate of barium by means of sulphate of ammonia, either from the liquors left after precipitation of the sulphide of zinc by means of sulphide of barium, or at the same time as the sulphide of zinc is precipitated, and together with it ; in either case producing a solution of chloride of ammonium of greater relative value than the sulphate of ammonia used. (3.) The combination of the ammonium sulphide produced by the distillation of the recovered ammonium chloride with vat waste from alkali works, for the preparation of sulphide of zinc from zinc solutions as described. (4.) The combination with the furnace in which the sulphide of zinc pigment is roasted, of an iron, brick or other condenser, for the purpose of recovering any chloride of ammonium which may be left adhering to it and which would otherwise be lost." —E. G. C.

XIII.—TANNING, LEATHER, GLUE AND SIZE.

Improvements in Manufacturing Leather from Seal Splits. R. and W. Baker, Bermondsey. Eng. Pat. 6438, May 13, 1886. 4d.

THE invention consists in the joint combination of the following processes :—The shaved and scoured skin is (1) "set" on a table and a composition made up of one-third French chalk and two-thirds Irish moss, starch or other similar body is worked on the skin to produce a face; (2) "strained nailed" on boards ; (3) dyed ; (4) softened by stoning ; (5) grained ; (6) a solution of moss or size, etc., applied to the surface ; and (7) polished by friction with suitable pads.—R. L. W.

An Improvement in Tanning. E. P. Nesbit, London. Eng. Pat. 7744, June 9, 1886. 4d.

THE patentee proposes to remove lime from unhaired hides or skins by placing them in a closed vessel with water and forcing carbonic acid gas into the water whilst keeping the hides agitated. The excess of the gas dissolves out the lime.—R. L. W.

Improvements in Tanning. A. J. Boult, London. From Count Vitold de Nydprück, Brussels, Belgium. Eng. Pat. 8582, June 30, 1886. 4d.

THE hides are tanned in a liquor made by boiling 1kilo. of catechu and 25grms. of tallow or other grease in a small quantity of water and diluting to 100 litres. The strength of this liquor is gradually increased during the tanning process till the tanning is complete. The colour of the hides is improved by finishing them in a bath made by boiling together 25grms. of divi-divi and 10grms. of grease and diluting to 100 litres. Other tanning matters may replace the catechu or divi-divi.—R. L. W.

An Improved Method of Tanning Hides and Skins. J. W. Abom and J. Landin, Stockholm, Sweden. Eng. Pat. 14,683, Nov. 12, 1886. 4d.

The patentees claim to hasten the tanning process by placing the hides or skins in tanning solutions through which an electric current is passed alternately in opposite directions.—R. L. W.

An Improved Method of Making Leather Waterproof or Flexible. E. and A. Dunkley, Northampton. Eng. Pat. 1562, Feb. 1, 1887. 6d.

The fat from twelve parts of mutton suet is heated to 100° C. with eight parts of wax, four parts of vinegar and one part of turpentine, and the leather is caused by suitable machinery to revolve slowly in the mixture. After this it is thoroughly kneaded till it is flexible and waterproof.—R. L. W.

XIV.—AGRICULTURE, MANURE, Etc.

Crude Phosphates of North Carolina. W. B. Phillips. Chem. Zeit. **11**, 417.

The form in which the phosphoric acid, amounting on the average to 20 per cent., is combined does not prevent their use in the manufacture of superphosphate, as the material is readily decomposed. The cost of extraction and transport is, however, so great that these deposits will only very slowly be brought into use.

—C. A. K.

Manufacture of Phospho Guano. L. A. Chevalet, Paris, France. Eng. Pat. 9636, July 26, 1886. 6d.

Instead of mixing sulphate of ammonia with superphosphate, as hitherto practised, the inventor uses carbonate of ammonia, either in the solid form or in the form of strong solutions, containing 24 or 25 per cent. of NH_3, and prepared according to his previous patent (Eng. Pat. 8819, 1886). The mixing is performed in any suitable manner, and the resulting manure, even when prepared from very acid and moist superphosphates, is neutral, dry and easily pulverised.—J. M. H. M.

Erratum.—In the June issue, p. 443, line 12 from foot of second column, *for* "2—3," *read* "2·3."

XV.—SUGAR, GUMS, STARCHES, Etc.

Improvements in the Manufacture of Sugar by Electrolysis. E. Fahrig, Eccles. Eng. Pat. 3556, March 13, 1886. 8d.

By means of a high-tension dynamo, electric sparks are passed through the raw sugar, the ozone thus formed bleaching the sugar and also loosening all base and mineral matters contained in it. Low-tension currents are then sent through the bleached mass and these produce a deposition of the impurities, which may be washed away by a stream of water.—B. T.

XVI.—BREWING, WINES, SPIRITS, Etc.

Removal of Fusel Oil from Crude Spirit. E. Pfeiffer. Chem Zeit. **11**, 347.

Potassium permanganate was tried in 1869 for the purpose of removing fusel oil from crude spirit. As the result of one experiment only, the yield of pure spirit seemed to be greater than with charcoal filters, but the use of the latter was considered more practical.

—C. A. K.

Improvements in the Manufacture of Yeast. W. S. Squire, London. Eng. Pat. 8082, June 17, 1886. 4d.

This is a modification of former patents by the same inventor. (Compare this Journal, 1886, 542, and 1887, 297.) It consists in sparging the solid substance from a malt mash with the spent wash from a previous operation, instead of adding the wash direct to the strong worts.—G. H. M.

Improvements in Means or Apparatus Employed in the Preparation of Finings for the Use of Brewers and Others. A. W. Gillman and S. Spencer, Southwark. Eng. Pat. 9090, July 12, 1886. 8d.

This consists of an apparatus by means of which the operation of passing finings through a sieve is greatly facilitated. The most important part of the apparatus is a brush which has both a rotary, as well as a rising and falling, motion.—G. H. M.

XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, Etc.

(A) CHEMISTRY OF FOODS.

Improvements in the Manufacture of Articles of Food made from the Kernels of Almonds and other Fruits. E. R. Allen and W. C. Allen, London. Eng. Pat. 9712, July 27, 1886. 4d.

The kernels are decorticated, crushed and the oil expressed, the last traces of the essential oil being removed by prolonged boiling or distillation. The dried meal so obtained is made into biscuits in the usual way.—C. C. H.

Improvements in Treating Milk for Preserving it. A. Brin, Paris, France. Eng. Pat. 9738, July 28, 1886. 6d.

The milk is saturated with pure oxygen under pressure, and bottled in a manner similar to the preparation of ordinary aërated waters.—C. C. H.

(B) SANITARY CHEMISTRY.

The Physiological Action of Sulphuretted Hydrogen and the Alkaline Sulphides. J. Pohl. Arch. f. Exper. Pathol. u. Pharm. **22**, 1.

The author considers that the poisonous effects produced by sulphuretted hydrogen are not due to its reducing the oxyhæmoglobin of the blood, for, according to his experiments, death can ensue before any reduction has taken place, but to the formation of alkaline sulphides with the alkaline salts of the blood. The alkaline sulphides possess specific poisonous properties.—C. A. K.

The Purification of Waste Water by Means of Iron Salts. Dingl. Polyt. J. **263**, 484—485.

In November, 1886, G. Wolff made a communication to the *Verein Deutscher Ingenieure* regarding the special advantages of employing iron salts in the purification of waste water; a method which until now has been impracticable on account of the expense. Puddle slag, with as much as 54 per cent. of iron, and mill furnace slag, containing 48 per cent. of iron, when ground with acids yield bodies which contain about 30 per cent. of iron, a small amount of silicic acid, a variable quantity of phosphoric acid and a deposit of mud, which, in combination with chalk, serve as a substitute for expensive purifying agents. Waste water when mixed with this prepared slag gives a dense precipitate, which quickly settles and leaves a perfectly clear water, which does not putrefy even after several months storage in open or closed vessels. If the water is alkaline or contains earthy alkaline carbonates, an addition of lime is often necessary, and even in drainage water which is slightly acid (through presence of organic acids), when phosphoric acid is present it is unnecessary to add lime on account of the insolubility of phosphate of iron solutions of organic acids. To make the precipitate more useful for agricultural purposes, prepared Thomas slag is used along with either of the above-mentioned slags. If it is necessary to reduce the amount of lime, the Thomas slag is treated with sulphuric acid, when the lime separates out as gypsum. The gypsum mud, which still contains some phosphoric acid, can, after the purification of the water, be added to the deposited mud, and so made useful. The presence of the iron does not, of course, detract from its employment as manure. Wolff states that for one cubic metre of waste water (*e.g.*, from paper works) a few grms. of iron in the form of prepared slag is sufficient.—W. M. G.

Improvements in the Disinfection of Sewage, Waste Liquors, and the like. F. Petre, Berlin, Germany. Eng. Pat. 4512, March 31, 1886. 6d.

This process for the purification of sewage and other such liquids consists in treating the liquid with caustic lime and subsequently with magnesium or barium salts, or both. The effluent from this defecation is further purified by filtration through gravel, charcoal, sawdust and tan or any material containing tannic acid. The process may be made more effective by treating the effluent with an alkaline phosphate and chloride of magnesium prior to the filtration.—C. C. H.

An Improved Means of Purifying, Precipitating, and Filtering Sewage, Drainage, and the like matters. J. Fenton, Batley. Eng. Pat. 7333, June 1, 1886. 6d.

The sewage is passed through a box or tank containing alum and admitted into settling tanks, the effluent passing therefrom being filtered through a series of strainers composed of straw or reeds.—C. C. H.

The Employment of Certain Substances for Antiseptic Purposes. W. Thomson, Manchester. Eng. Pat. 6819, May 21, 1886. 4d.

The patentee claims the employment of the neutral and acid fluorides and silico-fluorides of the alkalis, either alone or mixed with the free acids as general antiseptic. In some cases the proportion used may be as low as one part of the salt or salts to 1000 of the substance to be preserved and in others as high as two parts to 100.
—C. C. H.

Improvement in Disinfectants. A. Boake and F. G. Roberts, Stratford. Eng. Pat. 8509, June 29, 1886. 4d.

The patentees claim the employment of acid sulphite of zinc as a disinfectant; also a mixture of any of the following dry salts:—Calcium, magnesium, sodium, potassium and zinc sulphites or sodium and potassium bisulphites, with dry anhydrous sodium bisulphate sufficient in quantity that when wetted its free acid will decompose the sulphite with which it is mixed.—C. C. H.

Improvements in the Manufacture of Depurating and Decolourising Charcoal for Purifying Sewage and other Foul Liquids, and for Decolourising Syrups. W. Burns, Leith. Eng. Pat. 9569, July 24, 1886. 8d.

Sixteen parts of dried chalk and 6 parts of clay are ground to a fine powder with 12 parts of coal; 20 parts of wood sawdust are also added. The finely powdered mixture is then well incorporated with 40 parts of animal dung, 4 parts of blood and 2 parts of iron borings; the whole is moulded into bricks and these are calcined in a closed retort at a low temperature and at about 2lb. per square inch air pressure; a second stage of calcining at a high temperature and a lower pressure follows. Hydrochloric acid gas is then injected into the retort, afterwards superheated steam to absorb the acid, and finally after cooling, the charred mass is ground fine. The substitution of blood for the iron borings, and one half of the chalk and clay by ground bones, and proceeding as before, yields a carbon having a high decolourising as well as depurating effect. The specification gives drawings of the apparatus in which the calcination is effected.—C. C. H.

Improvements in Compositions for Treating Matters having an Offensive Smell. A. D. Hunter, Melbourne. Eng. Pat. 6037, April 25, 1887. 4d.

The object of the patentee is the production of a deodorant which shall not impair the valuable fertilising properties of any offensive matter to which it is added. The mixture described consists of 1 ton of dry lignite dust, 6 bushels of dried powdered leaves of the gum tree, 1cwt. of sulphate of iron, ¼cwt. of salt and 2 gallons of kerosene.—C. C. H.

XVIII.—ELECTRO-CHEMISTRY.

Pocket Form of Daniell's Dry Cell. Edelmann. Centralbl. f. Electrotech, **9**, 145.

Two plates of copper and two of zinc are separated from one another by sheets of filter paper. The paper is soaked in a hot mixture of gelatine and powdered copper sulphate on one side, and gelatine and powdered zinc sulphate on the other. Before fitting up the battery the sheets thus prepared are soaked in water and the plates are held together by indiarubber bands. With a resistance of 1 ohm, the battery has an electro-motive force of 2·04 volts, and the strength of the current, which is sufficiently constant, is 0·5 ampère.—C. A. K.

Crystals from Leclanché Cells. H. Thoms, Pharm. Zeit. **32**, 171.

Rhombic crystals of the formula $ZnCl_2.2NH_3$ were found in a Leclanché battery. They are insoluble in water but on boiling, ammonia is evolved. They can be obtained by dissolving freshly precipitated zinc hydroxide in a solution of ammonium chloride and evaporating till the solution commences to crystallise.
—C. A. K.

Improvements relating to the Application and Utilisation of Magnetism or Electro-Magnetism for the Separation of Metals and for other purposes, and to Apparatus therefor. H. S. Maxim, London. Eng. Pat. 4751, April 5, 1886. 1s. 1d.

This invention relates to the separation of non-magnetic metals from non-metallic substances, the separation being effected by allowing the mixture to fall between the poles of rapidly revolving magnets, the polarity of which is subject to continual reversals. The metals move in the direction of rotation of the magnets, and can be collected in a suitable chute, while the non-metallic substances fall straight down between the poles. This apparatus can also be used for assaying, by weighing ores in an ordinary balance and also when suspended between the magnet poles. The quantity of salts, saccharine matter, or acids in a solution can be ascertained by the same method. The larger the quantity of salts the greater the deflection.—B. T.

The Regeneration or Production of Chromic Acid from Exhausted Battery and other Solutions. D. G. Fitzgerald, London. Eng. Pat. 5542, April 21, 1886. 6d.

In batteries in which chromic acid or an acid solution of a chromate or bichromate is used, there is generally left a chromic salt and some sulphate of zinc. For convenience, this solution is poured into a tank, and the oxides of zinc and chromium are precipitated by lime or other base. The precipitate can then be easily transported to the regenerating works. Here it is redissolved by a dilute mineral acid or other suitable solvent and placed in a vessel, in which it is separated by a porous partition from a solution of zinc sulphate or of oxide of zinc in ammonia-alum. Into these two compartments dip electrodes that are not acted on by the solution. A current is then passed through, which liberates the acid of the chromium salt and oxidises its oxide of chromium into chromic acid. Zinc is deposited in the cathode compartments and may be separated by fusion from the oxide of chromium deposited with it.—E. T.

Improvements in Galvanic Batteries. S. F. Walker, Cardiff. Eng. Pat. 5817, April 29, 1886. 4d.

THE inventor proposes to use sulphur instead of manganese dioxide in a Leclanche cell. In the action which he believes takes place, the exciting liquid used at one stage of the action is renewed at another. The battery gives notice when nearly worked out by the liberation of sulphuretted hydrogen into the air.—E. T.

Improved Galvanic Battery. F. W. Branson, Leeds. Eng. Pat. 5855, April 30, 1886. 6d.

PLATES of carbon, which are placed generally in the outer vessel of the battery and surround the porous cell, are immersed in a solution, of which the essential components are chromic acid, sulphuric or nitric acid, and water. The zinc electrode is immersed in a solution of dilute sulphuric acid and any soluble mercury salt, but preferably sulphate of mercury.—E. T.

Improvements in the Mode of Vulcanising the Insulating Covering of Electrical Conductors. B. J. B. Mills, London. From J. J. C. Smith, New Jersey, U.S.A. Eng. Pat. 5828, May 12, 1885. 6d. (Amended Specification.)

IN the process of vulcanisation it is found of great importance to protect the wires from moisture and at the same time to subject them to pressure. This is at present done by packing in soapstone, or covering them with a tape impervious to moisture, and then subjecting them to the heat and pressure of steam. By this vulcanising process, however, the insulation resistance is found to be lowered and to fall farther when immersed in water. The inventor, therefore, covers the insulating material with tinfoil, thus completely protecting from moisture, and then subjects the cable to the direct action of high-pressure steam. Experiments show that by this process of vulcanisation the resistance is very much increased and is not affected by a long immersion in water.—E. T.

Improvements relating to the Extraction or Separation of Gold, Silver, and Platinum from Ores and other Substances or Products containing such Metals. J. Noad, East Ham. Eng. Pat. 6810, May 20, 1886. 6d.

THE finely pulverised material is allowed to subside in a bath consisting of a mixture of a saturated solution of any suitable iron salt with one of tungstate of iron. Into the deposit a cathode is introduced, the iron anode being in the solution and out of contact with the precipitate, and an electric current is passed, with the object of coating the particles of noble metals with iron, when they may be extracted from the residual matter by a magnetic separator. The iron may be subsequently removed by acid or by roasting.—W. G. M.

Improvements in the Transformation of Heat into Electricity, and in Apparatus for that Purpose. C. Clamond, Paris, France. Eng. Pat. 6869, May 21, 1886. 11d.

THE inventor connects an alloy of antimony and zinc with a substance such as galena or sulphide of lead by "intercontacts" of copper or other suitable metal. If one of these intercontacts connects the substances at one part and another at another part, then, when one intercontact is heated and the other cooled, a current of electricity is produced in the circuit. This principle is made use of in the improved apparatus.—B. T.

Improvements in obtaining Copper from Solutions of its Salts. E. Hunt, Glasgow. From G. Thomson, New Jersey, U.S.A. Eng. Pat. 6974, May 25, 1886. 4d.

COPPER PLATES, to serve as the positive electrode, and carbon contained in a porous vessel, to serve as the negative electrode, are immersed in the copper solutions. A current of electricity is passed through the cell until 90 per cent. of the copper has been deposited on the copper plates. The solution is then agitated with sulphide of iron, and afterwards allowed to settle; the clear liquor remaining is strongly acid, and may be used to dissolve fresh copper from oxides, etc.—B. T.

Improvements in Primary Voltaic Batteries. J. E. Pearce, Maidenhead. Eng. Pat. 7189, May 28, 1886. 8d.

THIS improvement relates to a battery similar to that described in Eng. Pat. 7461 of 1885, in which a current of chlorine gas is used as the excitant. A slab of carbon corrugated, or otherwise, and placed horizontally, serves as a porous partition and also as one of the electrodes; below and parallel with it is a slab of zinc immersed in zinc chloride. The whole is covered in by an earthenware cover or by the carbon element used as a cover, suitable passages being provided for the entrance and exit of the chlorine.—B. T.

Improvements in the Manufacture of Carbon Filaments or other Conductors for Incandescent Electric Lamps. W. Maxwell, London. Eng. Pat. 7251, May 31, 1886. 6d.

IN the usual methods of flashing, the hydrocarbon begins to decompose before the filament has become very hot and before the occluded gases have been expelled; the rate of deposit is also rapid and not easily controlled. The deposits are, on this account, only slightly adherent and not homogeneous. The inventor therefore encloses the filaments in a vessel through which a stream of neutral gas, such as nitrogen or hydrogen, is passing and heats them electrically as a preliminary purifying process. A continual stream of hydrocarbon gas or vapour, diluted with nitrogen or hydrogen in such proportions as will give the required rate of deposit, is then passed through and the flashing operation carried on at a much higher temperature than is usual. The gas is preferred at a low temperature and pressure. As the condition of the atmosphere round the filament remains practically constant, a very homogeneous deposit is obtained.—E. T.

Improvements in Galvanic Batteries. P. R. de F. d'Humy, London. Eng. Pat. 7353, June 1, 1886. 11d.

BY means of a lever the electrodes can be raised completely or only partially out of the liquid, according to the current required. The vessels containing the exciting fluid are arranged in trays, so as to be easily removed for renewing the liquid; each cell contains a porous vessel filled with the electrolyte, which gradually passes through the pores to renovate the liquid in the outer vessel.—B. T.

A New or Improved Electro-chemical Etching Process. H. E. P. Dorn, Leipzig, Germany. Eng. Pat. 7463, June 3, 1886. 4d.

THE parts of the metal plate which are to remain elevated are coated with a thin layer of some insulating substance; the plate is then connected by a wire to the positive pole of a battery and immersed in a bath of dilute acid sufficiently strong to chemically attack the metal of the plate; opposite to it is placed a plate of carbon or some negative metal connected to the negative pole of the battery.—B. T.

An Improvement in the Construction of Elements for Secondary Batteries or Accumulators. J. Pitkin, London. Eng. Pat. 7596, June 5, 1886. 8d.

THE frame of lead is cast with a flange along all four sides, and with studs at suitable intervals over both faces of the plate; these studs are cast taper, but are afterwards burred over by hammering so as to hold the active material of the plate; for the same purpose the flanges are either bent inwards or are undercut.—B. T.

Improvements in Secondary Batteries. C. Smith, London. Eng. Pat. 7848, June 11, 1886. 11d.

The electrodes are made of shallow leaden trays, divided by partitions into numerous compartments. Into these are packed strips of thin lead, alternated with either strips of asbestos paper or of some such substance as peroxide of lead. These plates are packed in a suitable containing vessel, with a thin plate of perforated vulcanite or such material between each pair and supported in such a way as not to touch either of the plates when the cell is in good order: this prevents any chance of a short circuit by buckling.—E. T.

An Improved Process for Producing Metallic Drawings or Designs, and Ornaments of all kinds on Metallic Surfaces. H. J. Haddan, London. From Johann von Chelmicki, Warsaw, Russia. Eng. Pat. 8078, June 17, 1886. 6d.

On the metallic surface to be treated, the parts to be left unaffected are painted over with an insulating ink or mass and then whatever metal is desired is electrodeposited on the exposed part of the metal surface. To produce a design in three metals—*e.g.*, gold, silver and nickel—the surface is first gilded, then nickeled, painted to the required design and silvered on the parts left exposed. The paint is removed from those parts that are to appear in gold and the nickel dissolved by a suitable acid.—E. T.

Improvements relating to the Extraction of Gold, Silver and Copper from Ores and other Substances or Products containing such Metals. J. Noad, East Ham. Eng. Pat. 8130, June 18, 1886. 6d.

See page 511.

Improvements in Secondary Batteries or Accumulators. A. M. Clark, London. From A. E. Peyrusson, Paris, France. Eng. Pat. 8226, June 22, 1886. 8d.

An electrode is employed, consisting of a block of peroxide of lead with vanes or wires of lead distributed through it and all connected to a central vertical lead rod. This electrode is placed in a porous vessel, the opposite electrode of lead or other suitable metal being placed round it, containing a solution made up of water, sulphuric acid and sulphate of tin or cadmium. When charging, either tin or cadmium is deposited on the lead plate; when discharging, this deposit is redissolved. For this electrode are claimed, great storage capacity, freedom from local action and the preliminary operation of "forming," and the possibility of seeing by the deposit of metal whether the accumulator is charged or run down. For the whole battery are claimed, freedom from short-circuiting, greater durability and an unusually high electromotive force and discharge current.—E. T.

Improvements in the Process of Pickling or Cleaning the Surface of Iron or other Metal previous to Coating such Surface with Tin or other Metal. A. Gutensohn and J. M. James, London. Eng. Pat. 8324, July 23, 1886. 6d.

A wooden bath is made of suitable form and size and lined with sheet iron; it is filled with an acid or alkaline solution, according to convenience. In it the metal sheets to be cleaned are suspended, and a current is passed from them through the liquid to the iron lining. The sheets become beautifully clean, while the iron which is removed, is deposited on the metal lining or, if the current be very strong, is deposited as oxide and may in either case be made use of. The "pickling" solution may be used for a long time and, being cold, gives off no noxious fumes. The inventor claims greater economy by this process.—E. T.

Improvements in Secondary Batteries or Electrical Accumulators. A. Reckenzaun, London. Eng. Pat. 8379, June 25, 1886. 6d.

In the usual forms of accumulator plates the active material is liable to be detached. The inventor therefore pours melted lead into a heated shallow tray, and distributes equally, by a continuous vibration or other suitable means, small pieces of active material of any chosen shape, placing a cover over to prevent them floating. By its contraction the lead binds them closely, decreases the above-mentioned defects and moreover gives great mechanical strength.—E. T.

Improvements in Incandescent Electric Lamps. J. G. Lorrain, London. Eng. Pat. 8413, June 25, 1886. 6d.

To overcome the well-known objections to thick leading-in wires in low-resistance lamps, the inventor substitutes several smaller wires, each wire being fused separately in the glass and joined together inside and outside for each of the larger ones.—E. T.

Improvements in the Manufacture of Carbon Filaments or other Conductors for Incandescent Electric Lamps. W. Maxwell, London. Eng. Pat. 8513, June 29, 1886. 6d.

The inventor "flashes" his filaments in the manner described in Eng. Pat. 7251, of 1886 (see abstract). The extent of the deposit is determined by the strength of current required to produce standard incandescence, and for the purpose of easily comparing the light with a standard, it is obscured by suitable means. The point at which the desired strength of current has been reached, may be indicated by a glow lamp placed in series, which then assumes a certain state of incandescence or just begins to glow; at this point, if desired, the current may be broken automatically by a "cut-out." To make lamps that will glow equally, whether in series or in parallel, filaments are chosen of exactly similar quality and size and, after flashing as above, are cut to the same length and mounted.—E. T.

Improvements in and connected with the Manufacture of Aluminium, and other Light Metals. F. J. R. Seaver, London. From Dr. E. C. Kleiner-Fiertz, Zurich, Switzerland. Eng. Pat. 8531, June 29, 1886. 8d.

Dry powdered cryolite is packed around and between carbon electrodes in a bauxite-lined furnace; on passing the current from a dynamo-electric machine, the heat of the arc formed between the carbons causes the fusion and simultaneously, the decomposition of the cryolite. The evolved fluorine, by attacking the bauxite, maintains the aluminium percentage in the electrolyte constant. When sufficient metal has collected, in the form of fused balls, around the lower or negative carbons, the circuit is broken and, after cooling, the aluminium is collected. Other light metals, such as magnesium or sodium, may be similarly reduced, but since they float upon the bath, the furnace must be closed by a tight-fitting bell cover to exclude oxygen. The form of furnace recommended is rectangular with symmetrically arranged cavities, the bottoms of which are pierced by the negative carbon; the positive electrodes are formed by groups of carbons in order to expose larger surfaces for contact. The various systems in each furnace are arranged in multiple arc and the positions of either sets of carbons may be regulated at will.
—W. G. M.

A Novel Saline Preparation applicable for use in Galvanic Batteries, and the Process for the Manufacture of the same. A. Schanschieff, London. Eng. Pat. 8832, July 6, 1886. 6d.

This preparation is composed of mercury and sulphuric acid, forming "a salt so freely soluble in water that 2lb. of metallic mercury may be held in solution in a gallon of water." Two methods of preparation are described.—B. T.

Improvements in Galvanic Batteries, and in the Application of the same to Electric Lighting and other uses. A. R. Upward and C. W. Pridham, London. Eng. Pat. 9082, July 12, 1886. 1s. 1d.

These are improvements on the gas batteries described in Eng. Pat. 15,567, of 1884, and Eng. Pats. 7461 and 9302, of 1885 (this Journal, 1886, 247 and 331). The inventors now employ extremely large circular cells, containing five cylindrical porous pots and two carbon plates between each pair of pots, all the remaining space being filled with broken carbon. The whole is sealed with marine glue. The porous cells contain the zincs and a solution of chloride of zinc. The gas generator has three openings—one connected to an acid vessel, provided with a gauge-glass to allow measured quantities of acid to be run into the generator; one to deliver the gas; and the third for emptying. The second tube has also a pipe with a tap jointed on, leading to a water reservoir, for cleaning out the generator. The gas when being made, passes first through the cells and then into the gas reservoir, consisting of four or more upright columns of drain pipes, the superior density of chlorine being taken advantage of. When the generator is not working, gas is sucked into the battery from these columns. The gas pipes that enter at the bottom of the cells may be connected with a trap to the drain, so as to get rid of any accumulation of liquid. For electric lighting two or more cells are employed, according to the size of the installation. A battery of accumulators is connected in series to the external circuit, and by means of a clock and a mercury switch-board, one, two or more cells, according to the size of the gas battery, can be connected to the latter in turn for regular intervals of time.—E. T.

Improvements in the Process for Treating Auriferous Substances by Electrolysis. H. Liepmann, London. Eng. Pat. 9432, July 20, 1886. 8d.

These improvements have reference to the apparatus described in Eng. Pat. 3873, 1883 (this Journal, 1884, 322) and consist in the addition of a dense porous diaphragm, which can be placed over the more porous partition, so as to prevent the diffusion of the cathode liquors into the anode compartment. Means are provided for putting this diaphragm either into or out of action.—B. T.

Improvements in Galvanic Batteries. E. H. Desolu, Paris, France. Eng. Pat. 9514, July 22, 1886. 8d.

To obtain great constancy, two porous pots are employed, an inner one containing the zinc, and an outer one; the space between the two is filled with a store of acid to replenish the weakened liquids of the active cells. Each vessel is provided with a special tap to enable liquid to be run in or withdrawn. Sometimes a third porous cell is employed, outside the above-mentioned two, containing a second zinc cylinder. This is then joined to the carbon of the next battery, as in the ordinary series arrangement. All the inner zincs are, however, joined together to the negative pole of the battery. It is stated that by this means a double electromotive force may be obtained.—E. T.

Improvements in the Deposition of Platinum by Electricity. W. A. Thoms, London. Eng. Pat. 10,477, Aug. 16, 1886. 6d.

To a solution of platinum chloride is added a weak solution of sodium phosphate and then one of ammonium phosphate. The mixture is boiled for several hours, some sodium chloride solution being added. Through the bath thus prepared a strong current of electricity is passed, and the bath is better if used warm. It must be kept up to strength by the addition of fresh platinum and sodium solutions.—E. T.

Improvements in Electrical Fuses. G. Smith, Polmont, N.B. Eng. Pat. 14,249, Nov. 5, 1886. 4d.

The inventor makes the fuse composition for blasting purposes into a paste by combining it with collodion, or a solution of rubber or shellac; the ends of the conducting wires are then coated with this material, which may be covered with sheep-gut and afterwards treated with shellac varnish.—B. T.

Improvements in and connected with the Manufacture of Aluminium and other Light Metals. E. C. Kleiner-Fiertz, Zurich, Switzerland. Eng. Pat. 15,322, Nov. 24, 1886. 8d.

The object of these improvements is to prevent the rapid destruction of the carbon anode immediately above the bath of melted cryolite, which occurs in the use of the arrangement described in Eng. Pat. 8531, of 1886 (see abstract, p. 517). To effect this, the anodes are moulded into segments, which are so placed as to form a carbon ring, and above this is placed a layer of oxide of aluminium to prevent access of air to the carbon. The bottom of the vessel is made concave, so that the metallic aluminium which is deposited may collect there and not form a short circuit between the carbons. The carbon rings have wings or connections, which extend beyond the furnace, to lead the current from the main circuit. The arc may be started initially by means of a carbon rod.

—W. G. M.

Improvements in Extracting Gold and other Precious Metals from their Ores, and Apparatus therefor. C. D. Abel, London. From E. Fischer and M. W. Weber, Berlin, Germany. Eng. Pat. 921, Jan. 20, 1887. 8d.

See page 512.

Improvements in Galvanic Cells. N. W. Perry, Norwood, Ohio, U.S.A. Eng. Pat. 1337, Jan. 27, 1887. 8d.

The conducting electrode consists of a plate of carbon perforated with small holes and floated horizontally with its upper surface above the level of the battery fluid, and also coated with paraffin or some similar substance. The occluded oxygen of the carbon acts as the depolariser. The zinc electrode passes through a hole in the centre of the carbon and dips in the battery liquid, which may consist of a solution of ammonium chloride.—B. T.

Improvements in Electric Batteries. C. G. Curtis, F. B. Crocker and S. S. Wheeler, New York, U.S.A. Eng. Pat. 2721, Feb. 22, 1887. 8d.

With this battery a mechanical device is provided, whereby the electrodes may be immersed to any required depth or be raised completely out of the battery solution.—B. T.

Improvements relating to Electric Batteries and to means for putting the same into and out of Action. G. V. Lagarde, Paris, France. Eng. Pat. 2835, Feb. 23, 1887. 11d.

By means of mechanism actuated by clockwork, the exciting fluid is constantly circulated, and the carbon electrodes rotated. The current also may be controlled at a distance from the battery.—B. T.

Certain New and Useful Improvements in Accumulators of Electricity or other Primary or Secondary Galvanic Batteries. C. Desmazures, Paris, France. Eng. Pat. 4219, March 21, 1887. 8d.

When a metallic precipitate or powder is subjected to very great pressure, it becomes agglomerated and has then the power of absorbing oxygen and hydrogen to a very large extent. The inventor employs a plate of metal, such as copper or iron prepared in the above way, as one electrode, enclosing it in a parchment envelope. The other electrode is of tinned iron, with tinned iron wire or gauze wrapped round it to give large surface. The electrolyte is a solution of chlorate of soda and zincate of soda or potash. In charging, water is decomposed and the oxygen absorbed by the porous plate; the hydrogen decomposes the zincate and zinc is deposited on the iron. On discharging, the zinc returns to solution by the help of the oxygen of the other electrode. It is claimed that the electromotive force and resistance are very constant, the efficiency is high and that no buckling takes place.—E. T.

Improvements in Electrodes applicable for Use in Primary or Secondary Batteries. L. Epstein, Martinikenfelde, Prussia. Eng. Pat. 4527, March 26, 1887. 8d.

THE inventor's object is to avoid short-circuiting by disintegration or buckling of the electrodes. He therefore employs strips of lead with the active material attached thereto in any of the well-known ways. These are fixed by one or both ends to a stiff lead frame, so that the whole electrode looks like a grid or railing. The distance between each strip is small, so as to prevent the active material if dislodged from falling between two opposite electrodes. In another method the inventor covers a cake of finely-divided "lead compound" with lead, and after varnishing the plate thus formed with some such material as Chatterton's compound, cuts slits or holes to expose the active material. Great capacity, mechanical strength and rate of charge and discharge are claimed for these electrodes, which may be constructed of other metals than lead.—E. T.

Improvements in the Construction and Manufacture of Zincs for Galvanic Batteries. W. E. Heys, Manchester. From J. Beattie, jun., Westport, Mass., U.S.A. Eng. Pat. 4571, March 28, 1887. 4d.

THE object of this invention is to cause mercury to amalgamate with zinc throughout its mass. For this purpose a metal, such as lead, containing a little arsenic, is placed in mercury just hot enough to dissolve it, a little carbonate of soda added and the amalgam poured into moulds and allowed to cool. This lead amalgam is then placed in a pair of perforated tongs, which completely encloses it, and moved vigorously about in molten zinc, or in zinc sufficiently hot to take the form of powder. By this means a thorough amalgamation is obtained, the arsenic helping the union of lead and zinc, and the sodium that of zinc and mercury.—E. T.

Improvements in Means for Supporting or Suspending Elements in Electric Batteries. H. I. Harris, London. Eng. Pat. 4744, March 30, 1887. 6d.

THE zinc or other elements are suspended by hooks passing through holes in their centres, the hooks consisting of either amalgamated copper or some metal similar to that of which the element is composed.—E. T.

XIX.—PAPER, PASTEBOARD, Etc.

A Process and Apparatus for rendering all kinds of Paper Impermeable and Transparent, said Apparatus being likewise applicable for rendering Cotton or other Fabrics Impermeable. E. de Pass, London. From La Société de Lafarge Lèbre et Compagnie, Paris, France. Eng. Pat. 7530, June 4, 1886. 8d.

IN Eng. Pat. 5242 of 1883 and Eng. Pat 15,075 of 1884 (this Journal, 1884, 443), certain processes are described for rendering fabrics, leather, skins, cork and other substances in general, impermeable. The substance used for this purpose is composed as follows :—

Turpentine paste	6kilos.
Tallow	1·5 ,,
Wax	0·5 ,,
Styrax (necessary and not optional)	0·2 ,,

The inventor has since found that a homogeneous substance is obtained. He now proposes to apply this mixture to all kinds of paper in order to make them transparent and impermeable to air or moisture. This transparent material is called styroleum and hydrofage cotton. The apparatus consists of two parts—viz., a sheet iron cistern for containing the above-named substance and a calendering apparatus.—H. A. R.

A New and Improved Process and Apparatus for Manufacturing Sulphite Cellulose in Beton Boilers. L. A. Groth, London. From H. Schnurmann and G. Close, Würtemburg, Germany. Eng. Pat. 7633, June 7, 1886. 8d.

THE object of this invention is to manufacture sulphite cellulose in a quicker, cheaper and more effectual manner in beton boilers by the indirect application of steam for heating in a specially arranged heater. The beton boiler is a fixed vertical cylinder composed of acid-proof masonry and cement enclosed in a leaden mantle and a thick coating of beton, the whole being bound together by iron bands and screws, connecting a crown and base-plate of sheet iron, each being provided with a cast-iron man-hole.

The heater consists of three double copper cylinders with cast-iron lead-lined covers, placed horizontally one above the other. Connecting pipes permit the circulation of the boiling liquid upwards into the boilers containing the material to be acted upon. Steam from a separate boiler circulates round these cylinders by means of outer jackets, which communicate by short tubes, or instead of double cylinders the steam may pass by a series of copper tubes through the heater.

In this way the wood will be entirely disintegrated, and becomes soft and tender, offering greater facility to felt. This kind of boiler has the advantage that loss of heat is reduced to a minimum, and the sulphurous acid cannot act on the iron parts in any way.

By means of the special heater rapid circulation of the boiling liquid will be effected, by which alone it is possible to produce throughout the whole of the boiler a homogeneous product. The heater can also be applied to horizontal boilers, and figures are given showing the same applied to a "Mitscherlich" boiler in which the direction of circulation can be reversed.—H. A. R.

A New or Improved Rotating Vat, principally for the Boiling of Cellulose. H. J. Haddan, London. From W. Woern, Gothenburg, Sweden. Eng. Pat. 8486, June 28, 1886. 6d.

THIS invention relates to rotating "vats," and is principally intended to be applied to those used for the boiling of cellulose. It consists in making the "vat" an elongated oval shape, "by which it is rendered much stronger and adapted to be more completely emptied than a cylindrical vat."—H. A. R.

Improved Method of Treating or Preparing Paper for the Manufacture of Floor and Wall Coverings; applicable also for Wrapping, Packing, and other like uses. John Luke, Denny. Eng. Pat. 8593, June 30, 1886. 4d.

THE inventor prepares a duplex paper by the process described in Eng. Pat. 2409 of 1877, with the addition that before being finished it is passed through a sizing machine in order to give it a coat of size, after which the paper is made waterproof by means of oil, paint, etc., put on by machinery or by hand. The paper may be printed if required and then either air or machine dried.—H. A. R.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

The Fat of the Soja Bean. T. Morawski and J. Stingl. Chem. Zeit. **11**, 82.

THE Soja bean contains 18 per cent. of fat. The oil extracted by ether has a sp. gr. of 0·9270. 0·22 per cent. of the oil does not saponify; when mixed with concentrated sulphuric acid a rise in temperature of 61° is noted. It belongs to the semi-dry oils, and resembles the oil of the pumpkin-kernel in its properties.

The fat of the soja bean contains 95½ per cent. of fatty acids, which in the free state melt at 28° and solidify at 25°.—C. A. K.

The Sugar of the Soja Bean. T. Morawski and J. Stingl. Chem Zeit. **11**, 82.

THE Soja bean contains 12% of sugar, partly saccharose and partly a non-crystallisable sugar. The latter gives mucic acid on oxidation, its specific rotatory power is greater than that of cane sugar and it is more difficult to invert.—C. A. K.

Raiz Pipi, a New Drug. Chem. Zeit. **11**, 348.

RAIZ PIPI is the seed of *Petiveria hexaglochin*, a plant belonging to the order *Phytolacca*, and found in Brazil. The Petiveriæ occur in the south of North America, South America and the West Indies in bare places, meadows, etc., as small bushy plants with clusters of white blossoms and pale green oval leaves. The fruit is of an oval shape and broader at the top than at the bottom. The whole plant, and especially the roots, have a strong garlic-like smell. This is not noticeable in the dried roots but appears again when they are moistened. Little is known either of the chemical or medicinal properties of these roots. They are used to a considerable extent, however, by the natives in the districts where they are found as a febrifuge, as a sudorific and as a remedy for gonorrhœa and toothache; also for washing wounds. One variety, *P. alliacea*, is employed by the Indians of Calderão (Brazil) in the preparation of curare. It is not poisonous.—C. A. K.

The Action of Croton Oil. Kobert. Chem. Zeit. **11**, 416.

THE author considers, in opposition to Senier's views (*Pharm. J. and Trans.*, 1883, 446), that there are two active principles in croton oil, one of which attacks the skin, while the other acts as an aperient: that both these effects are due to crotonolic acid (not to be confounded with crotonic acid), which was discovered by Buchheim in croton oil in 1873. It exists in the oil partly in the free state and partly as a glyceride. Senier also states that croton oil can be separated by means of alcohol into two fractions. This the author also denies, his experiments showing that the solubility of the oil in alcohol depends mainly upon its age. Some varieties are soluble in all proportions; while crotonolic acid itself is readily soluble in alcohol, the solubility of the oil bears no relation to the quantity of free crotonolic acid present. To separate this acid the oil is treated with an excess of a hot saturated solution of baryta water, and the precipitated barium salts washed with cold water and extracted with ether, whereby those of oleic and crotonolic acid are obtained in solution. The residue, after distilling off the ether, is exhausted with alcohol, in which the barium crotonolate dissolves, and from this solution the free acid is liberated by sulphuric acid. Crotonolic acid is liable to decomposition by hot baryta water, and this is the chief difficulty in its preparation.

—C. A. K.

Lobelia Inflata. Prof. Lloyd and G. Lloyd. Pharm. Rundschau, **5**, 32.

LOBELIN, the essential principle of *Lobelia inflata*, forms a colourless, amorphous, brittle mass, having a stroeg smell. The smell is due to a mixture of ethereal oils and inflatin, both of which are removed by washing with carbon bisulphide, when the lobelin is both colourless and odourless. Its salts, which could not be obtained in a crystalline form, are all powerful emetics. It is only sparingly soluble in water. Inflatin, which can also be extracted from the seeds of *L. inflata*, is a colourless body, without smell, insoluble in water, but soluble in carbon bisulphide, benzene and chloroform; it melts at 107° and does not combine with either acids or alkalis.—C. A. K.

Liquid Vaselin as a Solvent for Hypodermic Injections. Meunier-Lyon. Archiv. de Pharm. **3**, 97.

IODOFORM, carbon bisulphide, eucalyptol and other substances which act as irritants when injected subcutaneously, lose this objectionable property when dissolved in liquid vaselin. The vaselin used for this purpose must have a perfectly neutral reaction, and a sp. gr. of 0·870—0·895 at 15°. It should not evolve any vapours when heated to 180° and should possess neither taste nor smell. The fluorescence of liquid vaselin is no objection to its use. It acts as a ready solvent for hydrocarbons, but dissolves few oxygenated compounds. Ether, chloroform, fats, volatile oils, menthol, thymol, etc., are soluble in all proportions, as are large quantities of iodine, bromine and iodoform. According to Bocquillon, sulphuretted hydrogen is more soluble in liquid vaselin than in water; vaselin dissolving four times its own volume of the gas.—C. A. K.

Chia Seeds. L. Soubeiran. J. de Pharm. et de Chim. **15**, 260.

CHIA SEEDS are obtained from a species of Salvia. In taste and smell they resemble linseed. Chia oil, which is of a clear yellow colour, is similar to linseed oil, and like the latter possesses drying properties. The Mexicans consider the oil to be of great therapeutic value, while the seeds are used in the preparation of a refreshing beverage.—C. A. K.

Active Principles of the Alant Root (Inula Helenium). Marpmann. Phar. Centr. H. N. F. **8**, 122.

THE author confirms Korab's results as to the antiseptic properties of the constituents of the alant root against tuberculosis bacilli. By distilling the root with water helenin, alantic acid and alantol (alant camphor) are obtained. Alantic acid $C_{15}H_{22}O_3$ crystallises from alcohol in white crystals which melt at 91°, and sublime forming an anhydride $C_{15}H_{20}O_2$. Both the acid and anhydride are insoluble in water, soluble in alcohol and the fatty oils, and form easily soluble salts with the alkalis. Alantol is an aromatic liquid boiling at 200°. The author concludes from numerous experiments made on both man and animals that neither alantic acid nor alantol have any injurious action on the system.

—C. A. K.

Berberine. E. Schmidt. Arch. Pharm. **25**, 141.

THE author ascribes the formula $C_{20}H_{17}NO_4$ to berberine. It is obtained from the fluid extract of both *Hydrastis canadensis* and of *Berberis aquifolium* by treating with dilute sulphuric acid, the berberine sulphate obtained being washed with alcohol, then dissolved in hot water, and reprecipitated by dilute sulphuric acid.

Berberine forms a crystalline compound with chloroform, $C_{20}H_{17}NO_4CHCl_3$, which is almost insoluble in alcohol and water. It also combines with yellow ammonium sulphide similarly to strychnine, forming a polysulphide of the formula $(C_{20}H_{17}NO_4)_2H_2S_6$, which crystallises in brown needles.—C. A. K.

Ecgonine. W, Gintl and L. Storch. Monatsh. Chem. **8**, 78.

ECGONINE heated with methyl-iodide yields a methiodide addition product and not a hydriodic acid salt, as stated by Lossen. According to Merck, neither methyl-iodide nor hydriodic acid have any action on ecgonine.

—C. A. K.

Process for the Production of the Ethers of Morphinecarbonic Acid. A. Knoll, Ludwigshafen, Germany. Eng. Pat. 10,281, Aug. 11, 1886. 4d.

THE process is based on the reaction of the ethers of chlorocarbonic acid on morphine, on morphine-alkalis or on the morphine-compounds of the alkaline earths. To produce, for instance, the methyl-ether of morphinecarbonic acid, morphine is dissolved in alcohol. Alcoholic potash or soda is then added and afterwards a slight excess of methylchlorocarbonate. The reaction takes place at once and is attended with considerable development of heat. Subsequently, the mixture is neutralised with sulphuric acid, the alcohol distilled off and the residue dissolved in water. An excess of alkali is added and the methyl-ether of morphinecarbonic acid thus formed is taken up by benzene. The latter is evaporated, when the methylether remains behind as a crystalline mass. Other ethers are obtained in an analogous manner.—S. H.

Process for Producing Methyl-Morphine (Codeine), Ethyl-Morphine and Higher Homologues of Morphine. A. Knoll, Ludwigshafen, Germany. Eng. Pat. 10,387, Aug. 13, 1886. 4d.

If morphine or a compound of morphine and an alkali or earthy alkali be heated with methyl or ethyl-sulphate of potash or soda, the alkyl radicle of the latter enters the morphine-molecule in place of an atom of hydrogen or of metal. To produce, for instance, methyl-morphine (codeïne), morphine is dissolved in 90 % alcohol, to which potash or soda lye has been previously added. An excess of methyl-sulphate of potash is then introduced and the whole heated for two hours with the use of a back flow condenser, whereby codeïne is formed, the liquid becoming brown and turbid The separation of the latter and the recovery of the undecomposed morphine are effected in the usual manner. Other homologues of morphine are obtained in a similar manner.—S. H.

The Physiological Action of Acetphenetidine. O. Hindsberg and A. Kast. Centr. Med. Wissensch. 1887, 145.

Ethylated and acetylated *p*-amido-phenols and *p*-acetphenetidine in quantities of 3grms. acted like strong poisons. Experiments made on feverish persons show that the acetphenetidine is an effective antipyretic in doses of 0·2—0·5grm.—W. R.

XXI.—EXPLOSIVES, MATCHES, Etc.

Improvements in and connected with Explosive Cartridges for Blasting Purposes. T. Macnab, London. Eng. Pat. 6222, May 7, 1886. 11d.

This invention consists in part in the combination of and improvements upon certain features of the inventions described in Eng. Pat. 3150 of 1876, and Eng. Pat. 2143 of 1884, and may be briefly described as a combination of the "water cartridge" with the "ammonia cartridge."

"One form of combination cartridge comprises an outer case, which may be formed of cloth or of the material known as 'Willesden paper' or other suitable flexible material. At the far end of the case—that is to say, the extremity which is to occupy the bottom of the bore-hole—is placed a charge of tonite or other suitable explosive agent. Embedded herein may be a closed vessel or vessels containing liquid ammonia, liquefied carbonic acid gas or other similar acting fluid, the tonite being also furnished with an efficient primer or detonator cap, as hereinafter described, or otherwise, and with appliances for firing same. The remainder of the case is filled with water or is occupied by a tube of flexible material charged with water or other liquid adapted for extinguishing the flame resulting from explosion. The two ends of the cartridge case are closed and rendered water-tight; the extremity of the wire or other means for firing the charge being left projecting from the near end of the cartridge case." Arrangements to facilitate the insertion of the cartridge in the bore-hole, also for firing the charge by a mechanical exploder, are described. The use of an obturator, consisting of a cupped disc of compressed paper adapted to expand with the internal pressure generated by the explosion, and to fit the bore-hole tightly in combination with the cartridge described above, forms the subject of one of the claims. Drawings are given.—W. D. B.

Improvements in Electrical Fuses. G. Smith, Polmont, N.B. Eng. Pat. 14,249, Nov. 5, 1886. 4d.

See page 518.

Improvements in or relating to the Igniting of Explosive Charges and Combustibles. A. J. Boult, London. From L. Bagger, Washington, U.S.A. Eng. Pat. 3920, March 15, 1887. 8d.

In order to obtain certain and ready ignition of the explosive charge in shells or torpedoes by the direct action of water, a primer containing metallic potassium is made use of. Details are given of the plans adopted for the protection of the potassium from premature oxidation, and for ensuring its contact with water when required. The potassium or "water primer" may be combined with a percussion primer of any desired construction or with a time fuse. Drawings are given of such combinations. W. D. B.

Improvements in Explosives and in the Manufacture of the same. P. M. E. Audouin, Paris, France. Eng. Pat. 5899, April 22, 1887. 4d.

In the preparation of this explosive, designated by the inventor "Emilite," the portion of coal-tar oil boiling between 185° and 250° C. and soluble in alkalis, is subjected to the action of nitric acid and then converted into an explosive nitro-compound. It is preferred to extract the suitable portion of the coal-tar oils after removal of phenol, by treatment with alkaline solutions and subsequent decomposition of the alkaline compounds by means of any acid. The mixture thus obtained is subjected to rectification, in order to separate resinous matters, and then nitrated.—W. D. B.

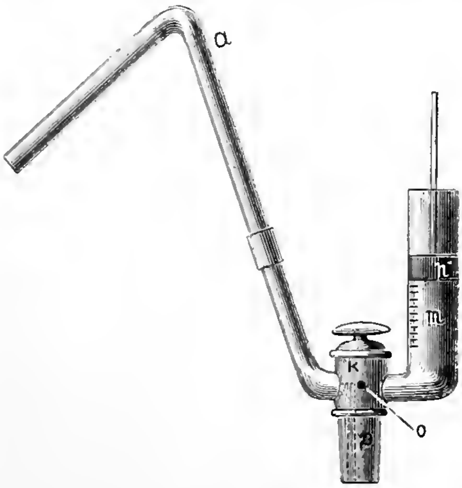
XXII.—GENERAL ANALYTICAL CHEMISTRY.

On a New Pyrometer. J. Mensching and V. Meyer. Ber. **20**, 582—583.

A complete account of this apparatus has appeared in the March number of *Ostwald and van't Hoff's Zeits. f. Phys. Chem.* It allows of the concurrent determination of temperature and vapour density, and has a special piece of apparatus for keeping the pyrometer filled with nitrogen, and excluding all possible traces of air. It is made of platinum. The vapour density of potassium iodide at 1320° was found to be 5·85 instead of the theoretical number 5·75.—J. B. C.

Siphon with a Cock. P. Raikow and N. Prodanow. Chem. Zeit. **11**, 348.

The long leg of an ordinary siphon *a* is connected with the three-way cock *k*, which has a horizontal aperture *o* and a vertical one *p*. To the other side of the cock the cylinder *m* with the piston *n* is fixed. By turning the cock through 90° from the position in the figure, *m* and *a* are connected, and by raising *n* the liquid is drawn through the siphon into the cylinder *m*. If now the cock be turned to its original position *m* is shut off, and the liquid runs out through *p*. To stop the flow the cock is turned through 45°, and thus the liquid can be run off as required. If the cylinder *m* be graduated the volume of liquid run off can be readily measured by first drawing the liquid into *m* by raising the piston and then connecting *p* and *m*, thereby closing the connection with *a*.
—C. A. K.



Improvements in Apparatus for Standardising and Measuring Intensity of Colour in Transparent Bodies. J. W. Lovibond, Salisbury. Eng. Pat. 12,867, Oct. 9, 1886. 8d.

THE principle of this instrument is based on the optical comparison of any liquid with a unit or combination of any number of units of colours of known or established value both viewed under the same conditions by transmitted light. *b* and *c* are two slightly divergent tubes, both viewed through a common eyepiece *d* by means of light transmitted through the ground, opal or darkened glass screen *bl*. The liquid under examination is put into the rectangular clear glass vessel *g* of known thickness in direction g^1g^2. One or more colour units of tinted glass *k* of known depths of shade are put into grooves in the other tube, until the transmitted light on both sides of the field are perfectly even. An exact measure of depth of colour in terms of the colour units can thus be obtained.—C. C. H.

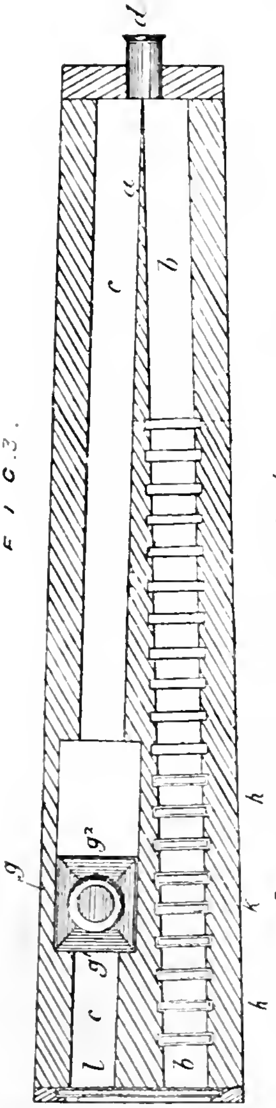


FIG. 3.

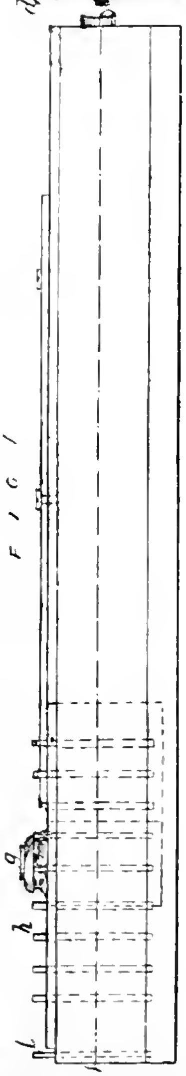

FIG. 1.

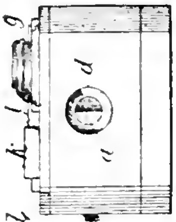

FIG. 2.

An Improved Cream Tester. P. V. P. Berg, Askor, and O. Sörensen, Kolding, Denmark. Eng. Pat. 4480, March 25, 1887. 6d.

TEST GLASSES, containing the milk under examination, are placed in holders, so suspended from the circumference of a rotating disc that, as soon as a high speed of rotation has been attained, the holders with the tubes become horizontal; and thus, by centrifugal action, the cream is rapidly separated from the milk, and their respective volumes are measurable. In the apparatus described, as many as 162 samples may be tested at once. —W. G. M.

Arsenic in Matches. E. Pfeiffer. Chem. Zeit. **11**, 416—417.

ARSENIC was detected in matches obtained in Jena by the characteristic smell of arsenic trioxide, which was evident immediately after striking, and before the sulphur began to burn. The match heads had a black covering with a metallic lustre, and contained much lead, partly present as red lead. The quantity of arsenic was, however, so small, that it could not be detected as sulphide, even by treating 50 match heads with hydrochloric acid and distilling, or by fusion with nitre and sodium carbonate. On the other hand, its presence was confirmed by Gutzeit's reaction. Ten matches were burnt at once under a porcelain dish, and the film treated with bromine water (to remove sulphur dioxide), washed into a flask, and reduced with zinc and hydrochloric acid, when the yellow colouration on a piece of filter-paper, moistened with a drop of nitrate of silver, was obtained.—C. A. K.

Arsenic in Ferric Chloride Solution (*Liquor ferri perchloridi fortior, B.P.*) G. Buchner. Chem. Zeit. **11**, 417.

THE author was able to detect arsenic both by Marsh's test and by the silver nitrate test in 10cc. of a supposed pure sample of ferric chloride solution.—C. A. K.

Notes on the Alkaloids. O. de Coninck. Compt. Rend. **104**, 233.

THE alkyl-iodides of sparteine and nicotine give delicate colour reactions when treated with caustic potash, in a similar manner to the corresponding compounds of the quinoline and pyridine bases. (This Journal, 1887, 59.) —C. A. K.

The Oxalate Test for Quinine Salts. L. Schäfer. Pharm. Zeit. **32**, 170.

THE oxalate test can be used for those neutral quinine salts which are not less soluble in boiling water than quinine sulphate. 1grm. of the quinine hydrochloride (2grms. of the sulphate or hydrobromide) are dissolved in 60grms. of boiling water, a solution containing 0·5grm. of neutral potassium oxalate in 5grms. of water added, and the whole made up to 67·5grms. The solution is allowed to cool at 20° for half an hour, and 10cc. of the filtered solution tested with caustic soda. A turbidity or precipitate shows the presence of admixed alkaloids. —C. A. K.

Detection of Aniline Colours. Curtman. Pharm. Rundsch, 1887, 61.

FURTHER TRIALS have established the utility of Hofman's carbamine reaction for the detection of aniline colours. In a test tube, 4cc. of the red wine or raspberry syrup to be tested, two drops of chloroform and 4cc. of a 10% alcoholic potash solution are mixed together, and the mixture warmed slightly for two minutes. The temperature is rapidly raised to the boil. If aniline colours are present the penetrating smell of carbamine is developed, and is evident even in the presence of the various ethereal odours of the wine. If no result is given, as with acid magenta, then add about 4cc. concentrated H_2SO_4, and the smell of carbamine will be at once formed. The presence of sugar retards the reaction. In this case some of the colour is extracted by means of alcohol, ether, or chloroform, and this solution employed for examination. This reaction can be employed without difficulty for testing small pieces of coloured materials. It is simply necessary to treat the pieces with alcohol or other solvent and examine the solution as before.—W. R.

New Method for Determining the Strength of Iodine Solutions. W. Kalmann. Ber. **20**, 568—571.

THE method is based upon the following reaction: $Na_2SO_3 + 2I + H_2O = Na_2SO_4 + 2HI$. A given volume of the iodine solution is mixed with so much sodium sulphite that the liquid is just decolourised. Methyl orange is used as indicator, and the amount of HI determined with decinormal caustic soda. It is essential that the sulphite should be free from bisulphite. The presence of sulphate is not objectionable. The same method may be used for titrating sulphites in presence of thiosulphates. The reactions are expressed as follows: $Na_2SO_3 + I_2 + H_2O = Na_2SO_4 + 2HI$; $2Na_2S_2O_3 + I_2 = Na_2S_4O_6 + 2NaI$. The application of the method is as follows:—Into a measured volume of standard iodine solution the mixed sulphite and thiosulphate is added until the liquid is decolourised. A few drops of methyl orange are added, and the HI titrated with decinormal caustic solution until the colour changes from reddish yellow to pure yellow.—J. B. C.

Determination of Zinc as Pyrophosphate. L. Jawein. Chem. Zeit. **11**, 347.

THIS method, as described by G. Stone (*Amer. Chem. Soc.* 4, 26), was tried with two samples of brass, the results agreeing well with those obtained by weighing the zinc as oxide. The solution is treated with ammonia and sodium phosphate, and the precipitate thus obtained, which is very difficult to filter, dissolved in an excess of ammonia, and this excess then removed by boiling. The precipitate then separates in a finely granular form, and can be readily filtered and washed. The zinc ammonium phosphate is ignited and weighed as zinc pyrophosphate ($Zn_2P_2O_7$). The method carried out in this way works smoothly, but boiling off the excess of ammonia takes a long time, and the precipitate sticks so fast to the sides of the vessel that it must be dissolved in acid, and reprecipitated by cautious neutralisation with ammonia.—C. A. K.

The Determination of Phosphoric Acid. C. Mohr. Chem. Zeit. **11**, 417—418.

THE author recommends the method suggested by Albert for dissolving phosphates and phosphatic slags, in which 2grms. of the substance are triturated in the cold with 100cc. of 2 per cent. sulphuric acid. 10cc. of the solution thus obtained are then treated after filtration with a 1 per cent. solution of potassium ferrocyanide, to precipitate the iron, and titrated with uranium acetate, after the addition of sodium acetate. The blue colour of the solution does not mask the end reaction.—C. A. K.

Determination of Potassium in Ash, Minerals, etc. M. Kretzschmar. Chem. Zeit. **11**, 418.

THIS method is a shortened form of that proposed by Stohmann. A hydrochloric acid solution of the substance is made if possible, the iron oxidised with nitric acid and the sulphuric acid precipitated by barium chloride. The solution is then treated with ammonia and ammonium carbonate in excess, and the whole (solution and precipitate) evaporated to dryness in a porcelain dish, dried at 110°, and extracted with water after addition of a few drops of ammonia. The solution is made up to 500cc., and 50—100cc. taken for the alkali determination. If much magnesium is present the solution must be again evaporated with oxalic acid, the residue gently ignited, and again extracted as before.

—C. A. K.

ERRATA.—In June issue, p. 457, line 36 from top of first column, *for* "Tetrobasic," *read* "Tetrabasic." Same column, line 48, *for* "tubes," *read* "tables;" and in line 59, *for* "grains," *read* "grammes."

New Books.

THE OWENS COLLEGE COURSE OF PRACTICAL ORGANIC CHEMISTRY. By JULIUS B. COHEN, Ph.D., F.C.S., Assistant Lecturer on Chemistry, Owens College, Manchester, etc. London and New York: Macmillan & Co. 1887.

SMALL 8VO VOLUME bound in cloth, with Preface by Sir Henry E. Roscoe and Prof. C. Schorlemmer, and the Author's Preface. In the latter it is clearly stated that "the book is only intended for the use of students who are undergoing or have undergone a substantial course of instruction in the principles of organic chemistry. Its primary purpose is that of a laboratory guide, and its use should be supplemented by reference to some of the large text-books as well as to the original sources of chemical literature mentioned at the head of each preparation. The little work is essentially a select collection of organic preparations, in which principal stress is laid on those details attention to which is likely to lead to the obtaining of a successful result in the shape of as good a yield of the product sought for as possible, in accordance with the method adopted. In each case, besides that purely chemical name of the preparation in question which expresses the composition and to some extent constitution, is given the special name and also the technological name, then the full formula, and following this the "Literature," where the accounts of the scientific work done on the subject can be read and studied. Dr. Cohen has also given special attention to the standard reactions in organic chemistry, and gives details for the correct methods of applying them; the references, too, with additional notes on these reactions, will be found in the Appendix, which consists principally of "Notes on the Preparations," followed by some useful tables. This portion of the little book is certain to be of great value and assistance to the student of organic chemistry. Exclusive of the Appendix, the subject matter occupies 165 pages, in which eighty-two preparations are described, and the text is embellished with thirty wood engravings. After descriptions of the purification of alcohol, ether and benzene, the study of the preparation and properties of a series of aromatic substances is commenced, and this occupies PART I. of the book. PART II. is devoted to a series of preparations taken from the paraffin or "fatty" series of organic substances. Of this arrangement the author says in his Preface: "The usual arrangement of fatty, before aromatic compounds, has been reversed for the reason that those of the latter which have been selected offer fewer difficulties to the beginner." A useful and wise direction to the student is offered by Dr. Cohen before beginning a preparation: "Read first the recent literature on the subject, reference to which will be found at the head of the preparation, and refer to it in your text-book." The work closes with a useful Alphabetical Index.

DIE KÜNSTLICHEN ORGANISCHEN FARBSTOFFE. Unter Zugrundelegung von sechs Vorlesungen von Prof. Dr. E. NOELTING; Bearbeitet von Dr. PAUL JULIUS. Berlin: R. Gaertner's Verlagsbuchhandlung, Hermann Heyfelder, Schönebergerstrasse 26, S.W. London: H. Grevel & Co., 33, King Street, Covent Garden, London, 1887.

8VO VOLUME bound in cloth. Contains Preface, Table of Contents, 224 pages of subject-matter, and an Alphabetical Index. The subject-matter contains useful tables or tabulated lists of the Coal-tar Colours, and is generally sub-divided into fifteen chapters. These chapters may be briefly headed as follows, thus giving a clear notion of the compass of the work:—CHAPTER I. Coal-tar; Constitution of Benzene and its Derivatives; of Naphthalene and its Derivatives, etc. CHAP II. Intermediate Products of the Colour and Dye-manufacturer. CHAP. III. Coloured and un-coloured Carbon Compounds; Dyestuffs; Witt's Chromophoric Groups; Chromogens, etc. Dyestuffs, themselves mordants. CHAP. IV. Nitro-bodies, etc. CHAP. V. Azo-colours, Diazo-compounds, etc. CHAP. VI. Derivatives of Triphenylmethane; History of the Rosaniline Derivatives, Synthesis and Constitution of Rosaniline, etc. CHAP. VII. Phthaleins, their Synthesis, Constitution and Derivatives, etc. CHAP. VIII. Artificial Indigo; Synthesis of Cinnamic Acid, etc. CHAP. IX. Anthracene Colours. CHAP. X. Pyridine and Quinoline Derivatives, etc. CHAP. XI. Indamine and Indophenols, Bindschedler's Green, Toluylene Blue and the simplest Toluylene Blue. CHAP. XII. Azines; Azonium Bases, etc. CHAP. XIII. Indulins and Nigrosins; Azodiphenyl Blue, etc. CHAP. XIV. Aniline Black. CHAP. XV. Appendix: Galloflavine; Cachou de Lavelle; Kanarin; Murexide, etc.

MODERN HIGH FARMING. A Treatise on Soils, Plants, and Manures. By FRANCIS WYATT, Professor of Agricultural Chemistry, Chemical Analyst, etc. New York: C. E. Bartholomew, 22, College Place. 1886.

8VO VOLUME, bound in cloth, containing Index, or rather a Table of Contents, and 94 pages of subject-matter. This matter is sub-divided into fifteen chapters, which may be briefly summed up as follows:—CHAPTER I. General Introductory Remarks; Influence of Climate; Origin of Scientific Agriculture, etc. CHAP. II. Theory of Scientific Agriculture, etc. CHAP. III. Minerals necessary and injurious to Plant Life. CHAP. IV. Phosphates. CHAP. V. Potash; its Action on the Soil, etc. CHAP. VI. How Soils lose their Nitrogen, etc. CHAP. VII. Physically Perfect Soils. CHAP. VIII. Progress of the Manure Trade in the United States, etc. CHAP. IX. The different kinds of Manure, etc. CHAP. X.

Farm-yard Manures, etc. CHAP. XI. Mineral Manures, etc. CHAP. XII. Sulphur: its occurrence in Nature, etc. CHAP. XIII. Sulphuric Acid Manufacture, etc. CHAP. XIV. Superphosphates, uncertainty of their Composition, etc. CHAP. XV. Chemical Analysis, etc.; how to read and understand Chemists' Certificates, etc.

GENEALOGICAL TREE, showing the more important Compounds existing in, and derived from Coal Tar by Distillation, together with those formed by further Chemical Treatment, the Connecting Links being maintained in continuity. Compiled by BENJ. NICKELS, F.C.S., F.I.C. Lawton & Co., Bank Buildings, 3, Manchester Road, Bradford, Yorks., or 109, Rusholme Road, Manchester. Published by Bemrose & Sons, London and Derby.

THIS scheme takes the form of a kind of Chart, mounted on canvas and glazed. It measures about 35 inches in height, by 26 inches in width. It may also be had with the Coal-tar Colours indicated by suitable colouring of the parts of the tree on which the names of the colours are printed. The price is 10s. 6d. plain, or mounted 12s. 6d. The statistics of Coal carbonised in the United Kingdom, Gas, Ammonia and Coal-tar produced are also given. A Chart of this kind might play a useful part in the Chemical Departments of Colleges and Technical Schools, as a kind of graphic index to the Coal-tar Products and Colours.

Trade Report.

(From the Board of Trade Journal.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

RUSSIA.

Recent Customs Decisions.

(*Note.*—Poud = 36lb. avoirdupois. Gold rouble = 3s. 2d.)

Spar or *terra ponderosa*, or sulphate of baryta, in pieces, Section 11. Duty, 4 copecks per poud.

Heavy spar in a pulverised state and sulphate of baryta, a chemical product in the shape of a kneaded mass corresponding with heavy spar, Section 128. Duty, 55 copecks per poud.

BELGIUM.

Modification of Customs Duties on Vinegar and Acetic Acid.

A despatch, dated the 15th June last, has been received from Mr. M. le M. H. Gosselin, Her Majesty's Chargé d'Affaires at Brussels, transmitting a copy and translation of a decree of the Belgian Government, modifying the rates of Customs duty on vinegar and acetic acid. The duties now charged on these articles are as follow:—

Vinegar or liquid acetic acids containing of pure acetic acid, 8 per cent. or less, 15frs. per hectolitre; more than 8 per cent. and less than 40 per cent., 75frs. per hectolitre; 40 per cent. or more, 187·50frs. per hectolitre. Acetic acid, crystallised, 187·50frs. per 100 kilogrammes.

NEW CUSTOMS TARIFF OF MEXICO.

See also pp. 273 to 295 of the December Number of the Journal.

With reference to the notification on p. 550 of the last number of the *Board of Trade Journal*, the following statement has been prepared, from information supplied by Mr. Lionel Carden, Her Majesty's Consul at Mexico, showing the articles in the new Mexican Customs Tariff, which came into force on the 1st July last, on which the duties have been altered, together with the rates of Customs duties hitherto levied on those articles.

In forwarding these particulars, Mr. Carden says that, in order to avoid being misled by apparent reductions, which, perhaps, really imply increased duties, it is necessary to pay great attention to the alterations in the class of weight on which the duty is leviable. For instance, in the case of cotton thread, which previously paid 1·60 dollars per kilog. *net*, the duty has been altered to 1·20 dollars per kilog. *legal*, the effect of which is to considerably increase the duty, in place of reducing it by 25 per cent., as would appear at first sight to be the case.

Note.—By "net weight," must be understood the actual weight of the merchandise; by "legal weight," that which includes, besides the "net weight," that of the interior bottles, boxes, winders, wrappers, etc., in which the articles are imported; and by gross weight, the total weight of the packages. When merchandise which pays according to the "legal weight," has no other covering besides the one which forms the outside package, the actual weight of the merchandise will be considered to be its legal weight.

Kilogramme = 2·204lb. avoirdupois.
Square Metre = 1·196sq. yards. Dollar = 1s. 2d.

UNITED STATES.

Customs Decisions.

Certain so-called partially manufactured Portland cement, which upon investigation was found to consist of partially-manufactured Portland cement, and which upon being ground may be employed as such without any further admixture of chalk or lime, and which in its condition as imported, readily sets upon being mixed with water, is held to be a species of cement, and as such, dutiable at the rate of 20 per cent. *ad valorem*, under the special provision in Section 11, for "cement Roman, Portland, and all others."

Certain "water of Cedar," a medicinal preparation, which upon investigation is found to be composed in part of alcohol, is held to be dutiable at the rate of 50 cents per lb., under the provision in section 118, for "all medicinal preparations * * * and medicated wines, of which alcohol is a component part."

After a thorough investigation, it is held that platinum wire, which has assumed that form merely for convenience in transportation, and which is not adapted for any known use as wire, does not come within the scope of the provision in Section 216, for "manufactures, articles, or wares * * * composed wholly or in part of * * * platinum," but is exempt from duty under the provision in the free list for "platinum, unmanufactured."

The Treasury Department's decision of October 31, 1883, under which unground talc was held to be free of duty as a non-metallic mineral substance, under paragraph 638, and ground talc as a manufactured mineral substance, under paragraph 95, is affirmed.

SWITZERLAND.

Classification of Articles in Customs Tariff.

(*Note.*—Quintal = 220·4lb. avoirdupois. Franc = $9\frac{6}{10}$d.)

The following decisions affecting the classification of articles in the Swiss Customs Tariff have been given by the Swiss Customs authorities during the month of May last:—

Fungivore (mixture of vitriol and flour of sulphur for arresting vine diseases). Category 16, duty 30 centimes per quintal.

Sulphate of nickel. Category 18, duty 2 francs per quintal.

Celluloid and articles of celluloid, except collars, cuffs, etc. (*see* above). Categories 348—352, duties from 4 to 30 francs per quintal.

Asbestos, in sheets or frames, not interwoven with other materials. Category 272, duty 3 francs per quintal.

Asbestos felt for roofing with tissues loosely interwoven. Category 299, duty 1 franc 50 centimes per quintal.

Cords of asbestos are expunged from category 306*a*.

Twine and plaits of asbestos, not interwoven with other materials. Category 307, duty 16 francs per quintal.

Asbestos cloth is included in category 311, to replace asbestos mixed with cloth. Duty 4 francs per quintal.

Proposed Modifications in Customs Tariff.

A Bill has lately been presented to the Federal Assembly for the purpose of revising the present Swiss Customs Tariff. The following is a list of the alterations in the proposed tariff revision.

(*Note.*—Quintal = 220·4lb. avoirdupois. Franc = $9\frac{6}{10}$d.)

No. in Customs Tariff.	Classification of Articles.	Proposed New Duties. Per Quintal.	Conventional Rates of Duty. Per Quintal.
	I.—WASTE MATERIAL AND MANURES.	Fr. Ct.	Fr. Ct.
2	Stable manure; compost; chalk-lime; residue of animal black; ashes (of bone, coal, peat, wood); loam; sweepings; rags and other waste materials intended for the manufacture of manure .... (This category in the existing tariff includes sulphuric acid once used.)	Free.	Free.
	Guano; phosphorites; phosphates; bone powder, etc.:		
3	Not chemically prepared, such as ammoniacal salts (crude), sulphate of ammonia, chloride of potassium, potash manure; sulphuric acid once used................	Free.	Free.
4	Chemically prepared; such as artificial manures .... [The grouping of Categories 3 and 4 has been amended.]	0·20	‡

39*a*	Oil varnish	10·00	7·00

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

SALE OF POISONS IN SWEDEN.

A despatch, dated the 22nd June last, has been received from Mr. E. Corbett, Her Majesty's Minister at Stockholm, on the subject of the regulations relative to the sale of arsenic and poisonous substances now in force in Sweden. Mr. Corbett says:—

"The Royal Decree of the 7th of January, 1876, relative to the sale of poisons, and the Decree of the 26th January, 1883, are still in force; but the Decree of 14th November, 1879, has been replaced by a Decree, dated 10th April, 1885, of which the following is a translation."

Section 20 of the Ordinance dated the 7th January, 1876, shall be altered to the following effect:—

1. Paper-hangings, roller-blinds, Venetian blinds, artificial flowers, and other articles in water-colours (with glue, gum, starch, dextrine, glair, and the like), printed or painted with arsenical colours, shall not be kept or offered for sale if, at a chemical analysis, out of 200 square centimetres (= 22·7 square inches) of the article, or less, metallic arsenic, precipitated as a black or blackish brown, at least partly opaque mirror (arsenic mirror) in a glass tube of 1½ to 2 millimetres (= ½ to ⅔ Swedish line) inner diameter, can be educed, by reduction with cyanide of potash and carbonate of soda, from the sulphuret of arsenic then obtained.

2. The same prohibition shall also be observed with respect to stuffs, woven fabrics, yarn, lamp shades, sealing-wax, wafers, composite candles and other candles containing arsenical colours or other arsenical substances, if metallic arsenic, in the manner and quantity above stated, can be educed from 100 square centimetres (=11·3 Swedish square inches), or less, of stuffs, woven fabrics, and lamp-shades, or from 21grms. (= 5 Swedish orts), or less, of any of the other articles above enumerated.

3. A certificate as to the quality of the article in this respect, and indicating the weight and surface measure of the sample of the article used, containing samples of all the colours of the article, shall be issued by a chemist conversant with the subject. This certificate shall also be accompanied not only by the metallic arsenic educed by the test, enclosed in a glass tube closed up at both ends, but also by as large a sample of the article examined as may be required for its identification or for a new analysis, if needed, but the sample shall not measure less than 500 square centimetres (= 56·7 Swedish square inches); and the glass tube, as well as the sample of the article, shall be securely fastened by a seal either to the certificate or to a paper containing the signature of the analyst, together with the number referred to in the certificate, which, moreover, shall be drawn up in accordance with the form annexed.

Form of Certificate as to the arsenical contents of goods.

At the chemical analysis of square centimetres (square inches, grams, orts) of the wall-paper (cloth, carpet, yarn, etc.) annexed marked number , containing samples of all its colours, made by me at the request of X, I have educed, by reduction with cyanide of potash and carbonate of soda, from the sulphuret of arsenic then obtained, the metallic arsenic which is enclosed in the glass tube attached (I have not found any arsenic present), and I therefore (owing to the nature of this arsenic mirror) declare the said wall-paper (cloth, etc.) prohibited (permitted) for sale or barter, in pursuance of the Royal Decree of the 10th April, 1885. The re-agents employed by me at the analysis have been examined by me and been found free from arsenic, which I hereby certify.

(Place and time.)

MISCELLANEOUS TRADE NOTICES.

DEPOSITS OF MANGANESE ORE IN THE UNITED STATES.

According to *Bradstreet's* for May 28th last, the following facts are given in Mr. Joseph D. Week's report on manganese to the United States Geological Survey:

"Ores containing manganese, described in this report, are divided into two classes—viz., manganese ores and manganiferous iron ores. Difficulty has been experienced in fixing the dividing line between these two ores. The standard of shipments in English chemical works, however, has been adopted—that is, 70 per cent. of bi-oxide, equalling 44·252 parts of the metal per 100. Ores containing less than this percentage of manganese can, however, be used in the manufacture of high manganese spiegel and ferro-manganese, while some ores with an excess of manganese may be used for low spiegels. Manganese is found widely distributed in this country. It is almost as plentiful as the deposits of brown hematite ore. Manganese occurs as a constituent of most of the latter kind of ores. Sometimes so much manganese is found in the ore as to make it a manganiferous iron ore. At other times veins or pockets of manganese are found alongside of iron ore. This is especially true in the case of the ores in the Appalachian ranges, and is particularly so in Virginia. Notwithstanding its wide distribution, only four localities yielded any considerable amount of ore in 1885. The places mentioned were the Crimora and Leete's mines in Virginia; at Cartersville, Georgia, and Batesville, Arkansas. The Crimora mine contributed two-thirds of all the manganese produced in the United States. Two other mines in Virginia produced a small amount of ore in 1885—viz., the Houston mines and those of the Shenandoah Iron Company. The production in 1885 was 26,495 tons, of which 23,258 tons were manganese ores, and 3237 tons were manganiferous ores. The origin of manganese has never yet been authoritatively settled. It is thought to be similar to hematite ore in origin, and to have been deposited from solution. So far as known the most valuable deposits of manganese have been found in pockets, usually imbedded in a tenacious clay requiring washing to remove."

---

* Duty payable under General Tariff, conventional rates being higher, except in the case of nitric acid, which will still pay 60 cents. per quintal.

GERMAN SUGAR BOUNTIES.

In the *Board of Trade Journal* for July will be found an analysis of the German Bill for reforming the sugar tax and bounties.

TRADE BETWEEN SPAIN AND THE UNITED KINGDOM.

RECENT TRADE BLUE BOOKS.

The following memorandum has been prepared in the Department with reference to Parliamentary papers bearing upon trade matters which have recently been circulated:—

1. ***Alkali, etc., Works Regulation Act, 1881. Twenty-third Annual Report on Alkali, etc., Works by the Chief Inspector.***—(C. 5057). *Price, 2s.*

This is the annual report of Mr. Fletcher, the Chief Inspector under the Alkali, etc., Works Act for the year 1886. It contains his reports to the Local Government Board and to the Secretary for Scotland, and is presented to Parliament pursuant to Act 44 & 45 Vict. cap. 37.

The report states that the number of works under inspection during the year was 910, or if Scotland be included, 1,018. This shows an increase of 13 English and 3 Irish works during the year. Of the above total of 910, 118 were alkali works as defined by the Act, and 792 were other works which come within the scope of the Act. In the year 1885 the numbers were 132 and 762 respectively, showing a diminution of 14 in the number of alkali works, and an increase of 30 in that of the other works.

In some of the works several distinct processes are carried on, each of which requires a separate examination on the part of the inspector; these are set forth below as distributed among the districts:—

LIST OF SEPARATE PROCESSES UNDER INSPECTION.

—	District I.—Ireland.	District II.—North of England.	District III.—Cheshire, N. Wales, Part Lancashire.	Sub-Dist.—Widnes.	District IV.—East Lancashire and Yorkshire.	Dist. V.—South Midland.	Dist. VI.—South-West of England.	Dist. VII.—South-East of England.	Total.
Alkali	2	12	17	16	11	3	4	2	67
Hydrochloric acid (cylinder)	—	—	—	—	17	3	—	8	28
Copper (wet process) ..	—	5	2	5	3	2	3	—	20
Cotton carbonising (alkali)	—	—	—	—	9	—	—	—	9
Sulphuric acid	15	24	21	18	43	28	46	32	227
Chemical manure	20	31	15	1	28	45	42	60	215
Gas liquor	—	2	3	—	14	1	—	1	21
Nitric acid	—	2	3	1	40	19	2	15	82
Sulphate and muriate of ammonia	14	27	22	4	48	53	57	66	291
Chlorine and bleaching powder	2	8	9	17	7	2	1	2	48
Salt	10	7	55	1	—	4	—	—	77
Cement	2	14	2	—	6	7	4	58	93
Total	65	135	149	63	226	167	159	244	1,208

During the year 1886 the number of separate operations under inspection was 1208, while in Scotland there was a further number of 187; giving a total for the United Kingdom of 1395. During 1885 the total number was 1368.

TABLE OF AVERAGE AMOUNT OF ACID GASES ESCAPING FOR EACH DISTRICT.

The following tables have been compiled by the General Inspector from the reports of all the examinations sent in by the inspectors on their visits to the works. The total number of visits made in the year was 4090, and the number of separate tests or analyses of gas was 4786:—

	Dist. I.—Ireland.	Dist. II.—North of England.	District III.—Cheshire, N. Wales, Part Lancashire.	Sub-Dist.—Widnes.	District IV.—East Lancashire and Yorkshire.	Dist. V.—South Midland.	Dist. VI.—South-West of England.	Average. 1886	Average. 1885
Hydrochloric acid in chimney gases. Grs. per cubic foot	0·12	0·11	0·07	0·11	0·08	0·09	0·10	0·10	0·10
Hydrochloric acid. Amount escaping compared with that produced, per cent. ..	—	2·40	1·79	2·60	2·18	2·10	2·34	2·13	2·39

The above figures are subject to revision in the Annual Returns.

NOTE.—The figures are those of the "special" imports and exports, except in the case of the United States and British India, where the figures are "general." "Special" means, in the case of imports, imports for home consumption, in the case of exports, exports of domestic produce and manufacture only.

* The aggregate figures are for the financial year commencing 1st April.

CHEMICAL IMPORTS AND EXPORTS FOR PAST HALF-YEAR.

During the past half-year we imported under the head of chemicals, dyestuffs and tanning substances, goods to the value of £1,579,250 as against £1,895,064 during the corresponding period of 1886, a decrease of £315,814. Our imports of Peruvian bark amounted to £116,188 as against £141,056 in the first six months of last year, a diminution of £24,868. Under the head of drugs unenumerated a diminution is also noticeable in comparison with the first half-year of 1886. The figures were £305,193 in 1887 and £357,182 in 1886, thus showing a decrease of £51,989. On the export side the figures came out rather better, although a slight diminution is still shown. The total value of chemicals and chemical and medicinal preparations exported during the half-year was £3,360,124 as against £3,368,265 in the six months ending June 30th, 1886. This is only a diminution of £8141.—*B. and C. D.*, 16th July, 1887.

THE KALI INDUSTRY.

According to the report of the sale convention of Strassfurt chloride of potash manufacturers, the despatchings for the second half of last year amounted to 1,005,028ctr. (879,032ctr. first half), giving an average price, after deduction of all petty charges, of 6501mks. (6552mks. first half) for 80 per cent. chloride of potash. The total despatchings for 1886 amounted to 1,881,060ctr., distributed as follows: Germany 886,960ctr., England 161,500ctr., Scotland 73,700ctr., France 136,700ctr., Belgium and Holland 137,900ctr., Italy 77,000ctr., North America 373,500ctr., Austria, Russia, Switzerland, etc., 79,300ctr. The report regrets that the German agriculturalists are yet very poor consumers.

THE OIL TRADE IN GERMANY.

The oil trade in Germany seems to be in quite as bad a way as is the Scotch trade, to judge by the following paragraph, which we take from *Kuhlow's Review*:—The report of the united Saxon and Thuringian paraffin and solar oil manufacturers for the business year 1886—87 shows that the fall in the prices of products is gradually increasing. The prices of paraffins are dependent upon those of fat goods, among which palm oil is the principal price regulator. Notwithstanding the increasing commerce with tropical countries from which palm oil is obtained, it is improbable that any lasting increase in the price of this oil will take place, and consequently the prospect of any definite improvement in paraffin, the most valuable product of the above company, cannot, at present, be entertained. The state of the market for paraffin oils is more favourable in consequence of the syndicate established last year, by which a decline in prices for the greater portion of the inland business is rendered impossible. Though a considerable percentage of last year's production of these oils remains unsold, and a small percentage at minimum prices has been exported, these facts need not occasion any anxiety, for while on the one hand the home consumption shows indications of increasing, on the other hand, the production was exceptionally high. Solar oil is being hard pressed by American and Russian petroleums. A portion of the year's production remains unsold. The following figures show the average prices per 100kilos. for the more important productions in the last two years:—

	1885—86. mks.	1886—87. mks.
Solar Oil	11·73	11·60
Dark Paraffin Oil	10·91	10·24
Hard Paraffin Oil	107·21	71·03
Soft Paraffin Oil	52·33	43·17
Paraffin Scales	42·77	29·53

The profits did not admit of any dividend being divided among the shareholders. A report which is identical with the above in all important details has been published by the Zeitz paraffin and solar oil manufacturers. In this instance, also, no dividend could be declared. An extraordinary general meeting of the united Saxon and Thuringian paraffin and solar oil manufacturers has decided on an amalgamation with the Zeitz paraffin and solar oil manufactory.

TRADE STATISTICS FOR JUNE.

The Board of Trade Returns for June show the following figures :—

Imports.

	June, 1886.		June, 1887.
Total value....................	£29,101,911	....	£27,555,217

Exports.

	June, 1886.		June, 1887.
British and Irish Produce	£18,536,076	....	£17,320,111
Foreign and Colonial Produce (partly estimated)	1,216,590	....	1,868,505

Below are the details affecting drugs and chemicals :—

DRUG IMPORTS INTO BOMBAY.

The import of drugs into Bombay during 1886 were largely in excess of those of the preceding year, as the following figures show :—

Imports.	1885.	1886.
	Rs.	Rs.
Chemicals	943,709	1,131,965
Drugs and medicines	1,534,778	1,576,550
Dye stuffs	1,490,974	1,585,172
Gums and resins	555,667	565,247
Quicksilver	66,058	118,866
Oils	2,391,196	2,969,288
Colours	608,112	815,274
Perfumery..................	389,066	331,714
Total..............	7,979,560	9,097,106

—*C. and D*, 25th June, 1887.

MISCELLANEOUS.

THE ANILINE TRADE OF GERMANY.

Kuhlow's Review says that the prospect of a slow improvement in the aniline industry has been fulfilled, and, but for the uncertain political situation of Europe which has lately had so damaging effect on all trades and industries, the improvement in question would doubtless have increased. The prices for the most important raw materials which are employed in the above industry reached in 1886 a normally low point. Certain reductions in the price of some of the products are also to be recorded. These, however, were on the whole moderate. The manufacture of fuchsin has just undergone a complete revolution in consequence of the employment of nitro-benzolin and the abandonment of the arsenic acid process. The manufacturers are now prepared to deliver a fuchsin and a blue absolutely free of arsenic compounds. Several modifications have had to be introduced into the machinery.

PROPOSED NEW DUTIES ON DRUGS IMPORTED INTO ITALY.

The duties are to be increased thus:—Acetic acid to pay 50 lire the 100kilos. instead of 10 lire; impure caustic soda raised from 50 centimes to 3·50; salts of quinine from 5 lire to 10 lire per kilo.; oxide of zinc from 2 lire to 5 lire; carbonates of soda and potash from 0·50 to 3·50; calcined magnesia from 20 lire to 50 lire; ordinary soap 8 lire instead of 6 lire; glycerin augmented from 30 to 60 lire; perfumery, alcoholic or otherwise, from 6·00 to 100 lire. On the other hand, mineral oil duties to be reduced from 27 lire to 10 lire; chicory from 20 to 15 lire; common sponges, now paying 20 lire, to enter free, but the duty on trimmed and prepared goods to increase from 20 to 25 lire.—*C. and D.*, 9th July, 1887.

ANTIMONY IN PORTUGAL.

It is not generally known, says the ***Financial News***, that some of the richest antimony mines in the world exist within a few miles of Oporto, in Portugal. For many years these mines have been worked by the natives, and traces of the old Roman workings have been found in nearly all of them. Lately a Portuguese company was formed, with a capital of £100,000, to work one of the mines, and under such management a dividend of 10 per cent was declared last year, and a very substantial sum added to the reserve fund. Immediately adjoining this mine there is a property which has, for some years, been worked by some of the English residents in Oporto, who have succeeded in opening up the mines to a point where the introduction of further capital becomes necessary. They therefore brought the Corgo Mines to the notice of English capitalists, with the result that they have since been purchased, and will shortly be offered to the public. Several hundred tons of the ores have been shipped, and sold to smelters here, the account sales showing an average of 60 per cent. of antimony to the ton. During the process of development a lode has been struck varying from 7in. to 3ft. 3in. in thickness, with a metallisation of pure antimonial lead. Visible gold appears in the quartz and antimonial lead, and assays have been made by several well-known experts, from samples as well as from bulk, and the average shows a mean return of over 22oz. to the ton. There are six distinct lodes in the Corgo Mine, and they have been opened up to a considerable extent. Two shafts have been sunk, one to a depth of 450ft., at which distance they have stopped for the present, and are now running new levels both east and west, where the lode shows itself from 3 yards to 5 yards thick, with abundant metallisation, having veins and pockets of pure antimonial lead from 2in. to 3ft. wide, besides auriferous quartz.

Monthly Patent List.

I.—GENERAL PLANT, APPARATUS AND MACHINERY.

APPLICATIONS.

8768 W. Oliphant, London. Apparatus for promoting combustion. Complete specification. June 17

8796 N. C. Cookson, Newcastle-on-Tyne. Construction of pipes for the conveyance of fluids, fumes, and gases. June 18

8801 R. G. Brooke and T. White, London. Improvements in and pertaining to condensers. June 18

8870 Mill, Comte, and Mabut, London. Freezing machines. June 20

8938 G. Donkin, B. G. Nichol, and H. Macarthy, Newcastle-on-Tyne. Apparatus for the effective circulation of water in steam boilers, and heating of feed water. June 23

8945 S. Smillie, Glasgow. Distilling apparatus for producing fresh water from salt water. Complete specification. June 23

9015 H. H. Lake, London—From A. P. Lighthill, United States. Improvements in atomisers. Complete specification. June 24

9017 O. Bruner and C. G. Rommenhöller, London. Pressure reducing valves for highly compressed gases, especially for carbonic acid. Complete specification. June 25.

9064 J. Orchard, London. Construction of valves for gases under high pressure. June 25

9102 F. W. Dick and J. M. McMurtrie, Glasgow. Apparatus for pumping and compressing fluids and for regulating fluid pressures. June 27

9118 J. H. Cormack, Glasgow. Improvements in and relating to doors for flues, soot boxes, and the like. June 28

9199 A. J. Boult—From J. Fischer, Austria. Apparatus for cooling or heating liquids, gases, vapours, and the like. June 28

9206 J. Howes, Liverpool. Rotary filtering apparatus. June 28

9250 A. M. Clark—From T. D. Williams, South Africa. Amalgamating apparatus. June 29

9410 P. A. Newton—From R. A. Chesebrough, United States. Improvements in hot-air furnaces. Complete specification. July 2

9422 P. Everitt, London. Filters. July 2

9424 A. Tolhurst, Gravesend. Hollow fire-bars for furnaces of boilers, kilns, retort benches, stills, etc.; and smoke consuming apparatus for the same. July 2

9441 L McIntyre, London. Heating feed-water by steam for steam boilers, and extracting impurities from same. July 4

9456 J. Willoughby and A. Gledhill, London. Method and apparatus for consuming smoke in the furnaces of steam and other boilers. July 4

9460 C. E. Hudson, London. Improvements in furnaces and in the method of supplying fuel thereto. July 4

9463 H. Schellhaas, Liverpool. Revolving furnaces for drying, heating, combining, or decomposing substances. July 4

9501 W. P. Thompson—From the Aerated Fuel Company, United States. Furnaces for burning hydro-carbon fuels, and steam generators therefor. July 5

9521 S. H. Johnson and C. C. Hutchinson, London. Construction of filter presses. July 5

9537 R. Hamilton and T. McKillop, Glasgow. Apparatus for promoting combustion, and other furnaces. July 6

9539 W. Davidson, Glasgow. Apparatus for feeding fuel into furnaces. July 6

9606 P. Everitt, London. Filters. July 7

9691 J. Batson, H. Sedgley Batson, and W. G. Causer, Birmingham. Apparatus for charging steam boilers with anti-corrosive liquids, semi-liquid, or other substances. July 11

9746 M. Vinning, London. Apparatus for regulating or controlling the flow of fluids from reservoirs in which such fluids are contained under pressure. July 12

9797 T. Kirkwood, London. Grates for furnaces. Complete specification. July 12

9820 T. T. Edwards, Birmingham. Filtering apparatus for drawing off liquids. July 13

9870 H. Wilson, Stockton-on-Tees. Apparatus for heating, cooling, and condensing fluids, gases, and like elements. July 14

9952 F. Weldon, London. Compressing apparatus. July 15

10023 W. Tapp, Bristol. A water softening apparatus. July 16

*COMPLETE SPECIFICATIONS ACCEPTED.**

1886.

9098 E. Fischer and M. W. Weber. Improvements in amalgamators. July 16

9785 S. Smithson. Method and apparatus for heating furnaces by means of ground coal or coal dust, and for consuming smoke. June 29

10641 D. Rylands, B. Stoner, and R. Potter. Arrangements for feeding melting furnaces. June 29

10978 J. J. Roylo and J. Brown. Apparatus for rapidly heating or cooling liquids. July 13

10983 H. Montgomerie. Collecting and using the waste heat from steam boilers. July 13

11169 J. Williamson. Filter-presses. July 2

11178 J. R. Fothergill. Furnaces or apparatus for effecting combustion of fuel with air under pressure. June 29

11304 C. Hird. Filters for filtering water for manufacturing purposes. July 6

11477 W. P. Singleton. Improvements in valves or cocks. July 6

11589 D. K. Clarke. Filter-presses. July 16

12498 J. Brookbanks. Composition for removing scale or other incrustations from steam boilers. July 13

1887.

2915 J. Critchlow, T. Forester, W. Forester, H. Forester, and L. Forester. Filter-presses. July 9

6807 J. W. Hyatt. Water purifier and filter for steam boilers. July 6

7011 J. Fleischer and C. Muhlich. Valve for liquid carbonic acid. July 6

7515 C. A. Koellver. Filtering and lixiviating press. July 16

7525 H. H. Lake—From U. Cummings. Air compressing apparatus. June 29

7817 J. Kroog. Apparatus for automatically discharging water of condensation from steam pipes, etc. July 9

7830 W. Macnab, sen., W. Macnab, jun., and J. Donald. Apparatus for separating, by subsidence, solid matters from the liquids in which they are suspended. June 29

7901 J. M. Chase. Steam boilers or generators. July 13

8044 H. H. Lake—From H. Ogden. Cocks or faucets. July 6

8180 W. H. Farris. Steam generators. July 9

II.—FUEL, GAS AND LIGHT.

APPLICATIONS.

8890 E. Renshaw, Manchester. Improvements in apparatus for moistening and cooling or heating air in rooms or buildings. June 22

8903 W. P. Thompson—From C. Drevs, Germany. Improvements in machines for crushing colza. June 22

8919 E. J. Palmer, London. A regenerated lamp for illumination and heating. June 23

8953 R. B. Avery, New York. New and useful improvements in method and apparatus for generating gas or gases for illumination, heating, and metallurgical purposes from liquid hydrocarbons and steam, and liquid hydrocarbons and air. Complete specification. June 23

---

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

9077 S. Pitt—From J. R. Knapp, United States. Improved apparatus for producing intense heat and artificial light. Complete specification. June 25

9162 E. O. Eaton—Partly communicated by J. Lancaster, United States. Improvements in fuel cartridges. June 28

9332 F. R. Baker, Birmingham. A new or improved lamp, or system of illumination. July 1

9391 C. S. Ellery and J. Challin, London. Improved means for preventing the choking of pipes between the retort and hydraulic main in gasworks. Complete specification. July 2

9403 C. Rave, Liverpool. Improvements in or relating to the treatment of the acid residuums resulting from the refining of mineral oils by concentrated acids. July 2

9128 W. Patterson. See Class X.

9936 C. H. McEwen—From J. C. Alexander and W. F. Maddox, New South Wales. Improved apparatus for regulating the pressure flow of gas. July 15

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

11287 A. Paget. Manufacture of "mantles" for use in incandescent gas lighting. July 6

11300 A. C. Thomson. Apparatus for treating mineral oils with acids or alkalis. July 6

1887.

1072 A. J. Boult—From E. Hamélius. Gas generators. July 13

3118 J. A. Marsh. Apparatus for producing gas or vapour from hydrocarbons, and for utilising gas or vapour for lighting or heating, and for igniting gas. July 6

7182 R. de Soidenhoff. Means or apparatus employed in the manufacture of coke for the desiccation and incineration of precipitants or solids, resulting from sludge or other substances liable to putrify. June 25

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10957 T. Nikiforoff. Production of benzol, anthracene, napththaline, and other products from naphtha and naphtha residues. June 29

11581 T. Rouet. Construction and arrangement of mechanical retorts for the destructive distillation or revivification of animal, vegetable, and mineral matters. July 13

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

8734 and 8735 R. Hunt. See Class XI.

8932 A. Ewer, P. Pick, and M. Lange, London. Process for the preparation of sulphuretted derivatives from the aromatic oxy compounds. June 22

9191 J. Imray—From La Societé Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, A. F. Poirrier, Z. Roussin, and D. A. Rosenstiehl, France. Manufacture of azoic colouring matters, shading from yellow to orange, and from red to violet. June 28

9257 J. Imray—From the same. Manufacture of new azoic colouring matters. June 29

9299 G. Tall and W. P. Thompson, Liverpool. Improvements in, or relating to, the separation or the manufacture of colouring matter or mordant for dyeing purposes from cotton seed or cotton-seed oil. June 30

9315 J. Imray—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, A. F. Poirrier, and D. A. Rosenstiehl, France. Manufacture of yellow, orange and red azoic colouring matters. June 30

9381 J. Imray—From the same. Manufacture of azoic colouring matters. July 1

9414 J. Imray—From the same. Manufacture of yellow, orange, red and violet azo colouring matters. July 2

9458 T. D. Lichtenstein, London. Improvements in the production or application of matters or media suitable for use for writing, printing, dyeing and colouring, and analogous purposes. July 4

9468 T. R. Shillito—From J. R. Geigy, Switzerland. Production of a new red azo colour. July 4

9624 R. J. Waters, Manchester. Powdered aniline writing inks. July 8

10046 C. A. Bennert, London. The manufacture or production of colouring matters. Complete specification. July 18

COMPLETE SPECIFICATION ACCEPTED.

1886.

8431 J. Imray—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, A. F. Poirrier and D. A. Rosenstiehl. A process for the manufacture of anthraquinone. July 13

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

8721 W. Ambler and W. O. Blackburn, London. Improvements in machinery for washing wool or other fibres. June 17

8815 H. J. Simpson, G. de M. MacKirdy, and A. Taylor, Liverpool. An article of manufacture from the bark of a certain tree, being a textile material applicable for use in textile manufactures, including lint and wood-wool; and process employed in obtaining such article. June 18

8865 E. Edwards—From F. J. Maizier and F. J. W. Reitz, Belgium. Improvements in machinery or apparatus for separating textile fibres from the stalks or stems of plants. June 20

9270 H. M. Girdwood, Manchester. Improvements in retting, ungumming, washing, etc., rhea, ramie, or China grass, hemp, flax, jute and certain other fibres. June 30

9274 E. W. Serrell, jun., Paris. Process and machinery for reeling silk from the cocoon. Complete specification. June 30

9692 J. Hebblewaite, Manchester. Improvements in the treatment of textile fabrics. July 11

VI.—DYEING, CALICO PRINTING, PAPER STAINING AND BLEACHING.

APPLICATIONS.

8803 C. L. Klauder, London. Improvements in dyeing and scouring yarns. Complete specification. June 18

9027 W. Crowther and J. Crowther, Dewsbury. Mordanting or fixing mordants upon worsted or woollen fibres, and upon mixed fibres of wool, cotton, silk, jute, etc. June 25

9184 E. D. J. Neupert, London. Improvements relating to the production of coloured designs upon plates, sheets, or other articles of celluloid. June 28

9211 R. Crompton, London. Improvements in colouring and drying tissue and other paper, and apparatus therefor. June 28

9361 T. M. Denne, London. A novel method of producing defined patterns in celluloid. July 1

9720 C. Meadowcroft and P. Denanhouer, London. Improved apparatus for dyeing skeins. Complete specification. July 12

9722 W. P. Thompson—From J. Meikle, United States. Improvements in apparatus for cleaning and bleaching cotton and other fibrous and textile fabrics. Complete specification. July 12

9710 B. J. B. Mills—From E. Smith. See Class XVIII.

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10933 E. Sutcliffe and G. E. Sutcliffe. Method and apparatus for bleaching, damping and dyeing loose fibre, yarns, threads, etc. June 29

10998 B. J. B. Mills—From F. Vladimirovitch Serikoff and W. E. Smith. Process and apparatus for bleaching cotton, linen and other textures and materials. June 29

11164 W. E. Heys—From H. Danzer, A. Simian, and D. Marcien. Method of dyeing and finishing textile fabrics simultaneously without immersion. September 29

11730 H. J. Haddan—From A. Henry. Improvements in dyeing. June 29

1887.

6737 C. Collin and L. Benoist. Process for fixation of the colouring matter, by oxidation at high temperature of the textile fibres. July 13

VII.—ACIDS, ALKALIS AND SALTS.

APPLICATIONS.

8820 C. T. G. Vautin, London. Improvements in the production of liquid or compressed chlorine. Complete specification. June 18

8922 W. N. Hartley and W. E. B. Blenkinsop, London. Improvements in the manufacture or preparation of cobalt sulphate, and its separation from other sulphates. June 22

9188 E. Hanisch and M. Schröder, London. An improved process and apparatus for the production of sulphuric anhydride. Complete specification. June 28

9227 C. Wigg, Liverpool. Improvements in the manufacture of bicarbonate of soda, and in apparatus therefor. June 29

9543 H. C. Bull and Co., Limited, and W. E. Sendey, London. An improved process for the manufacture of sulphate of ammonia, the recovery and purification of the by-products arising therefrom, and apparatus therefor. July 6

9760 A. Walker, Glasgow. Improvements in the manufacture of sulphates of soda and potash, and in the apparatus employed therefor. July 12

9873 E. W. Parnell and J. Simpson, Liverpool. Improvements in the production of sulphuretted hydrogen in combination with the manufacture of alkali by the ammonia process. July 14

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

7011 J. Fleischer and C. Mühlich. Valve for liquid carbonic acid. July 6

9158 P. Higgs. Process and apparatus for obtaining spelter and caustic soda, chloride of lime, chloride of calcium, etc. July 13

10191 J. Barrow. Improvements in the manufacture of alkali. June 25

10955 J. I. Watts and W. A. Richards. Manufacture, purification, and separation of sodium bicarbonate. June 29

11518 J. M. Collett. Manufacture of sodium sulphates. July 9

11311 J. W. Kynaston. Improvements in the manufacture of chloride of potash. July 20

1887.

6209 R. L. Hickes. Combining disinfectants with soda crystals. July 2

8820 C. T. J. Vautin. Production of liquid or compressed chlorine. July 20

VIII.—GLASS, POTTERY AND EARTHENWARE.

APPLICATIONS.

8752 E. Edwards, Brierley Hill. Improving and simplifying the tinting, staining and colouring of manufactured glass. June 17

8835 L. A. Fry, London. Improvements in the art of decorating clay ware. June 20

8886 J. Bentley and W. S. Simpson, Hanley. Improvements in producing on porcelain or other ceramic products, etc., designs in colours, gold, silver and other metals. June 22

8888 J. P. Guy, Longport. Improvements in potters' saggars. June 22

9074 W. H. L. Cooper, London. Making, finishing and drying plain or socketed stoneware, sanitary pipes or tubes. June 25

9080 S. Bunting, Dublin. Improved moulds, with apparatus attached for blowing glass. June 27

9195 M. R. von Spaun, London. Improvements in the manufacture of coloured glass-ware. June 28

9291 M. F. L. Ehrlich and C. T. Storck, Berlin. Improvements in a method of producing a bright printing gold, silver or platina Complete specification. June 30. (See 9292)

9292 M. F. L. Ehrlich, Berlin. Improvements in the method of producing dead gold (silver or platine) decorations on china, crockery-ware, glass, enamelled metals, etc. Complete specification. June 30

9529 C. G. Picking and E. Bussy, London. Producing art and other ornamentations on and in glass, or on enamel or ceramic-ware in relief. July 5

9711 W. Starley, London. Improvements in toilet ewers or jugs, chamber utensils and other vessels made of china, earthenware or glass. July 11

9957 J. Trassl and H. Lindner, London. Improvements in and relating to the manufacture of thin plates and other articles of glass. July 15

10001 E. Smith and F. Smith, London. Improved method or means of producing sparkling, brilliant effect in or from glass alone, or from a combination of glass and metal or metallised material. July 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

11233 H. Doulton. Improvements in making Bristol stoneware. July 9

12118 E. H. Pearce and H. Besson. Machinery for working glass. July 13

1887.

797 M. Hussy and W. Clark. Manufacture of roofing and other tiles and slates. July 5

1495 E. H. Pearce and J. Hills. Apparatus for bevelling small pieces of glass. July 9

3258 R. E. Donovan, F. Hazlett, and J. Johnston. Apparatus for blowing glass by mechanical means. July 13

3907 T. E. Halford and R. Morant. Method of making glass-lined metal articles. July 2

6177 W. P. Thompson—From M. C. Stone. Ornamentation of glazed earthenware articles. July 6

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

APPLICATIONS.

8939 J. Crombie and J. Crombie, Middlesbrough-on-Tees. Improvements in laying down or constructing concrete pavements, floors, or the like. June 23

9039 F. Naumann, London. Process and apparatus for producing improved faced bricks. June 25

9160 J. Ashworth, London. An improved refractory material, and appliances for use in the manufacture of the same. June 28

9605 G H. Innes, London. Improvements in manufacturing Portland and other cement, and apparatus therefor. July 7

9627 F. Pilkington, London. A method of fireproofing columns, stanchions, girders (iron and steel), ceilings, walls, flooring or buildings in any position. July 8

9691 F. W. S. Stokes, London. Improvements in the continuous manufacture and burning of cement. July 11

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

7492 W. Brierley—From F. Wallbrecht and H. Russe. Manufacture of artificial elaterite or elastic bitumen to be employed in road-making, roof-surfacing, etc. July 6

14312 T. Arnold. Process and apparatus for moulding briquettes of cement or the like material to be employed for testing its quality. June 29

1887.

7539 A. Smith, J. Roberton, and J. R. Andrew. Improvements in making Portland cement. June 29

7611 F. Wicks. Paving for flooring and building purposes. July 9

X.—METALLURGY, MINING, ETC.

APPLICATIONS.

8717 O. Schulz, London. Improvements relating to the elimination or removal from metal of acid or other liquids with which the same has been treated. June 17

8840 J. J. Arnold, Southampton. Improvements in armour plating. June 20

8866 W. Cross, London. Improvements in the manufacture of aluminium alloys. June 20

8930 F. C. Bellinger, London. Improvements relating to the joining or uniting of metal plates. June 22

8957 H. Defty, London. An improved process of extracting and refining metals from ores. June 23

8968 J. Toussaint, London. Improvements in the manufacture of iron and steel. June 23

9001 H. Johnson, London. Improvements in rammers used in tamping blast holes in the blasting or getting of coal and other minerals, and for other like purposes. June 24

9017 W. Cross. See Class XVIII.

9026 J. A. B. Bennett and W. Sunderland, Birmingham. Improvements in the mode of manufacturing aluminium chloride. June 25

9093 J. A. B. Bennett and W. Sunderland, Birmingham. Improvements in the methods of mixing metals of lower boiling points with other metals or alloys or compounds boiling or volatilising at higher temperatures. June 27

9103 J. Y. Johnson—From A. de Méritens, France. An improved process for electro-plating with tin, zinc and lead. June 27

9169 E. Patterson, London. Improvements in miners' safety lamps. June 28

9174 G. H. Jones, London. Improvements in the manufacture of mining implements. June 28

9200 A. G. Greenway, Liverpool. Improvements in the manufacture of iron or steel. June 28

9231 J. Toussaint, Birmingham. Improvement of converter, which has the advantage of operating without employing any machinery or blower. June 29

9235 J. Treherne, Llanelly. Improvements in miners' safety lamps. June 29

9286 A. Crighton and R. Crighton, Handsworth. An improved segmental metallic core bar for the casting of different kinds of metal thereon. June 30

9313 A. Mann, London. Improvements in alloys of aluminium with other metals. June 30

9316 R. A. Hadfield, London. Improvements in the manufacture of steel. June 30

9322 J. J. C. Smith, London. Improvements in means or apparatus employed in casting metals under pressure, June 30

9331 J. J. Hardy, Stockton-on-Tees. Improvements in miners' safety lamps. July 1

9365 C. E. Miles, London. Improvements in blast furnaces for smelting ores. July 1

9389 C. A. Burghardt and W. J. Twining, Manchester. Improvements in the production of aluminium. July 2

9428 W. Patterson, Low Fell. Improvements in electric safety lamps for use in coal mines and all other places where explosive gases are present. July 4

9471 J. B. d'Arcy Boulton, London. Process and apparatus for casting metallic ingots in a sectional mould. July 5

9474 J. Parkinson, London. Improvements in the treatment of ores. July 5

9499 A. J. Boult—From W. H. Larimer, United States. Improvements in drills for mining purposes. Complete Specification. July 5

9533 R. Thompson, Wigan. An expander for breaking down coal and other minerals. July 6

9568 N. C. F. Jochumsen, Barrow-in-Furness—From J. Hansen, Denmark. Improvements in the construction of furnaces for melting iron, steel and other metal. July 7

9572 A. E. Tucker, Smethwick. Improvements in the utilisation of flux skimmings or galvanisers' waste. July 7

9586 A. Mann, London. Obtaining aluminium and alloys of aluminium with other metals. July 7

9681 A. N. Contarini, D. Forbes and R. Matthews, London. A novel means and apparatus for the extraction of platinum from any ore containing same, and also gold from auriferous ferruginous sand. July 9

9706 J. B. Clark and The Panther Lead Co., Limited, London. Improvements in condensing and separating lead fume, and apparatus therefor. July 11.

9782 R. K. Boyle, London. Improvements in treating metals for modifying, hardening or alloying the same, applicable more especially to the case-hardening of iron or steel. July 12

9795 H. J. Smith, Glasgow. Improvements in and connected with the making of moulds for casting metal articles. July 12

9867 L. A. Brode, Glasgow. Improvements in treating pulverulent iron or iron compounds for smelting furnaces. July 14.

9868 A. G. Greenway, Liverpool. Improvements in the method of and apparatus for the manufacture of galvanised and tinned iron. July 11

10013 W. P. Thompson—From Mons. Faurie, France. Improvements in the manufacture of aluminium, magnesium, calcium, and similar metals and their alloys. July 18.

10057 E. de Pass—From M. Bernard and E. Bernard, France. A process for the extraction of aluminium from its fluorides by electrolysis. July 18

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

8989 E. Cottam. Manufacture of German silver. July 6

10062 W. P. Thompson—From W. H. Wright. Manufacture or working of metals in a cold state into certain forms, and apparatus therefor. July 6

10089 R. Heathfield. Apparatus for coating iron and steel with zinc or with alloys of zinc or other coating metal or alloy. July 6

10157 R. Evans. Apparatus for compressing scraps of metal into forms for re-melting or other use. July 9

11776 J. E. Baugh and C. Hinksman. Furnaces for chlorinating ores, and process in connection therewith. July 16

11816 A. Brin and L. Q. Brin. Manufacture of metallic oxides. July 20

11817 J. S. McArthur, R. W. Forrest, W. Forrest and G. Morton. Obtaining gold, silver, etc., from ores or other compounds July 16

12237 W. Fairclough and W. Warburton. Reflecting appliances for use in miners' safety lamps. July 13

12356 A. Brin and L. Q. Brin. Manufacture of iron and steel. July 20

12720 C. Heusler. Producing silicious copper and utilising the same for metallurgical purposes. July 20

15097 D. P. G. Matthews. Manufacture in sections of ingot moulds, and method of using and treating such moulds. July 9

1887.

1279 W. Patterson. Miners' safety lamps. July 9

5029 R. Hannan and M. Milburn. Obtaining zinc from its blende or sulphide. July 20

5501 A. L. Keeport. Separating metals from their ores or from crude minerals. July 20

7198 W. A. Baldwin. Obtaining aluminium from its ores or from aluminous earths, or earths containing alumina, and combining aluminium with other metals. July 20

XI.—FATS, OILS AND SOAP MANUFACTURE.

APPLICATIONS.

8734 R. Hunt, Liverpool. Improvements in the treatment of cotton-seed oil to refine and clarify the same, and to obtain colouring matter. June 17

8735 R. Hunt, Liverpool. Improvements in the treatment of cotton seed to obtain oil feeding cake and colouring matter. June 17

8825 R. Oxland, Plymouth. Improvements in the refining of oils and fats. June 18

8947 G. Tall, Liverpool. Improvements in the manufacture or purification of cotton-seed oil. June 23.

9376 J. Harris, London. Improvements in the manufacture of soap, specially applicable to scouring and other cleansing compounds. July 1

9943 W. A. Mitchell—From M. von Schmidt, Austria. Improvements in the purification of vegetable oils and fats, and the obtainment of useful products therefrom. July 15

9944 W. M. Riddell, Forest Hill. Improvements in the purification and oxidation of oils. July 15.

9953 T. H. Gray, London. Improvements in the mode of refining vegetable oils for illuminating or alimentary purposes. July 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10833 H. H. Lake—From La Société Anonyme du Compresseur Jourdan. Apparatus for expressing oil from oleaginous substances. June 25

11192 H. W. Langbeck. Treatment of wool fat to produce unguent material therefrom. June 25

11560 J. E. Quayle. An improved washing powder. July 2

11741 W. Graff. Separation of fat and fatty acids from compounds containing the same. July 16

12216 J. Kirkpatrick. Manufacture of oil for Turkey-red dyeing, calico printing, etc. July 2

12799 C. Schill and C. Seilacher. Oxidising oils and fats and other organic substances. June 29

13765 J. Stott. Apparatus for treating waste lubricating oils. July 9

XII.—PAINTS, VARNISHES AND RESINS.

APPLICATIONS.

9122 J. F. F. F. Lowe, London. An improved process of manufacturing white lead. Complete specification. June 27

9618 S. Washington, Manchester. An improved compound for application to iron work as a paint or varnish. July 8

9887 J. Rust, London. A new and improved material for colouring paints, cements and other substances. July 14

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

11493 A. McLean and R. Smith. Preparation of colours for artistic purposes. July 13

1887.

7524 H. H. Lake—From J. P. Perkins. Manufacture of pigment or paint. June 29

XIII.—TANNING, LEATHER, GLUE AND SIZE.

APPLICATIONS.

9088 N. Proctor, Alfreton. The utilisation of curriers' shavings and waste leather by the use of chemical and mechanical appliances; to be used for insoles, etc. June 27

9353 W. P. Thompson—From J. P. N. Bidrow, France. Improvements in compounds for use in tanning, and in the manufacture of the same. July 1

9404 M. J. A. Darglos, Liverpool. A process of carotting skins. July 2.

9193 H. H. Lake—From A. M. Bowers, United States. Improvements in machines for softening and otherwise treating leather. Complete specification. July 5

9215 E. Worms and J. Babe, London. Improved process and apparatus for tanning by the aid of electricity. July 5

9545 R. Ward, London. The treatment of rhinoceros hide and its manufacture into articles of furniture and ornament. July 6

XIV.—AGRICULTURE, MANURES, ETC.

APPLICATIONS.

9543 H. C. Bull & Co., Limited, and W. E. Sendey. See Class VII.

10,060 T. Roxburgh, London. An improved process of making manure. Complete specification. July 18

XV.—SUGAR, GUMS, STARCHES, ETC.

APPLICATIONS.

8748 W. T. Crooke, London. Improvements in pockets or bags employed in the manufacture of sugar and like substances, together with an improved process for cleaning the same. June 17

9690 C. Leuchtenberger and B. Moiske, London. Improvements relating to the purification of molasses and other saccharine solutions. July 9

9751 E. J. P. Robet, Paris. Process for treating vegetable milky juices, and extracting therefrom indiarubber, guttapercha, mangabeira, and such like. Complete specification. July 12

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

11451 S. Vickers. Apparatus for making lump sugar. July 13

11861 T. C. A. Carré. Moulding sugar, and apparatus therefor. July 20

12012 H. H. Lake—From T. F. Krajewski. Treatment of sugar cane for the extraction of sugar therefrom, and apparatus therefor. July 9

12535 A. Brin and L. Q. Brin. Manufacture of sugar. July 16

1887.

7259 F. Harm. Converting the syrups from sugar-manufacture into mono-saccharates. July 2

XVI.—BREWING, WINES AND SPIRITS.

APPLICATIONS.

8986 W. W. Davenport, Birmingham. New or improved apparatus for automatically regulating the temperature of fermenting liquids, applicable for other similar uses. June 24

9045 O. Brunler and C. G. Rommenhöller, London. Means for impregnating beer and other liquids with carbonic acid in the cask. Complete specification. June 25

9046 O. Brünler and C. G. Rommenholler. Process and apparatus for automatically mixing liquids with carbonic acid. Complete specification. June 25

9048 O. Brunler and C. G. Rommerhöller. An improved apparatus for using carbonic acid in large quantities. Complete specification. June 25

9049 O. Brünler and C. G. Rommenhöller. Process and apparatus for the automatic mixing of liquids with carbonic acid. Complete specification. June 25

9219 A. G. Greenway, Liverpool. Preserving ale, beer, porter, and other fermented liquors in barrels. June 29

9363 G. C. Jacquemin, London. The manufacture of wine from barley and other grain. July 1

9425 E. J. Taylor, London. Improvements in the manufacture of spirits. July 2

9505 J. Wetter—From E. T. Gautier, Belgium. Process or processes for the manufacture of alcoholic liquors. July 5

COMPLETE SPECIFICATION ACCEPTED.

1887.

4138 O. Imray—From F. W. Weisebrock. Process and apparatus for drying and cooling malt, etc. June 29

XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, ETC.

APPLICATIONS.

A.—CHEMISTRY OF FOODS.

9247 J. F. V. Steenberg, London. Improved process for preserving fish, meat, and other victuals. June 29

9319 W. H. Gilruth, London. Mechanically treating tea leaf in what is known as the fermentation process. June 30

9419 Prince J. Tarchan-Mouranoff (called Tarchanoff), London. Improvements in the treatment of eggs, or the albumenous portions thereof, for preservation, transport, and use as food. July 2

9950 L. Stollwerck and C. Stollwerck, London. An improved method of preserving fruit, vegetables and other articles of food. July 15

9956 A. C. Drenkham, London. Improvements in apparatus for evaporating or boiling milk and other matters. July 15

B.—Sanitary Chemistry.

8800 F. W. Lacey, Brentford. Improvements in apparatus connected with the treatment of sewage. June 18

8999 W. Horsfall, London. A new or improved construction of furnace for burning towns' or other refuse. Complete specification. June 24

9040 B. C. Badham, London. Certain improvements in and apparatus for purifying gases arising from sewers, surface water drains, closets, etc. June 25

9755 R. Weaver, London. An improved means of treating sewage and other matters. July 12

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1886.

10076 A. Dutour. A process for making the bones in fishes eatable. July 6

11995 W. G. Dunn. Improvements in baking powders. July 13

1887.

8008 T. A. Marshall. Preparation of farinaceous substances for use as food. July 6

8063 J. C. Mewburn—From J. J. Bate. Processes for preserving crustacea, and certain new and useful chemical solutions of special utility in such connection. July 6

XVIII.—ELECTRO-CHEMISTRY.

APPLICATIONS.

8855 E. Julien, Liverpool. Improvements in and appertaining to electric piles and plates therefor. June 20

8856 H. Aron, Liverpool. Improvements in apparatus for measuring electric currents. Complete specification. June 20

9011 E. Jones, London. Improvements in the construction of dynamo-electric generators and motors. June 24

9013 C. Coerper, London. Improvements relating to dynamo electric machines. Complete specification. June 24

9017 W. Cross, London. An improved method of heating ores and other substances by an electric current for effecting metallurgical, chemical and other operations, and furnaces or apparatus therefor. June 24

9104 A. P. Trotter, H. W. Ravenshaw and W. T. Goolden, Clapham. Improvements in dynamo-electric generators and motors. June 27

9196 A. J. Boult—From S. Doubrava, Austria. Improvements in apparatus for changing or regulating electric currents. Complete specification. June 28

9215 E. Worms and J. Babé. See Class XIII.

9654 J. J. Shedlock, London. Improvements in galvanic batteries. July 8

9725 W. P. Thompson—From G. Westinghouse, jun., United States. Improvements in dynamo-electric machines. July 12

9726 W. P. Thompson—From G. Westinghouse, jun. Improvements in armatures for electric generators. Complete specification. July 12

9727 W. P. Thompson—From G. Westinghouse, jun. Improvements in or relating to commutators for electric machines. Complete specification. July 12

9810 B. J. B. Mills—From W. E. Smith, Russia. Improvements in bleaching by electrolysis. July 12

9829 T. Stanley, London. Improvements in dynamo-electric machines. July 13

9853 H. Watt, London. Improvements relating to dynamo-electric machines. July 13

9871 J. Gibson, Glasgow. Improvements in or connected with electro-dynamic and dynamo-electric machines. July 14

9876 R. Dick and R. Kennedy, Glasgow. Improvements in and relating to dynamo-electric machines. Complete specification. July 14

9904 L. Grabau, London. Improvements relating to the production of insulated coatings or linings in electrolytic apparatus. July 14

9979 R. E. B. Crompton, Chelmsford, and J. C. Howell, Llanelly. Improvement in circulation of electrolyte in electric depositing vats, accumulators, etc. July 16

10057 E. de Pass—From M. and E. Bernard, France. See Class X.

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

8573 J. T. Armstrong. Portable electric batteries and appliances. June 25

9016 Sir W. Thomson. Apparatus for measuring the efficiency of an electric circuit. June 25

10765 W. Lowrie and C. J. Hall. Secondary generators for the conversion of electrical energy by induction. June 29

11487 S. Farbaky and S. Schenek. Manufacture of positive pole-plates for secondary batteries. July 16

11834 C. E. O'Keenan. Improved primary battery. July 16

1887.

7527 R. M. Hunter. Electric motors or dynamo-electric machines. July 2

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

8782 J. Wood and R. Wood, Glasgow. Improvements in apparatus for straining paper pulp and the like. June 18

8817 H. J. Simpson, G. de M. MacKirdy and A. Taylor, Liverpool. A manufacture of cellulose or wood pulp from a certain tree bark and wood, and treatment and process employed for obtaining such material. June 18

8861 G. H. Mallary, London. Improvements in the manner, method or mode of treating esparto grass and other fibrous materials for paper-making and other uses. June 20

8862 G. H. Mallary. An improved machine or apparatus whereby fibrous materials, such as esparto grass, may be reduced to pulp for paper making and other uses. June 20

8969 H. Gardner—From S. S. Stevens, United States. A novel process of manufacturing pulp for paper, and in apparatus for the purpose. Complete specification. June 23

9211 R. Crompton. See Class VI.

9294 G. Kirkman, London. An improvement in glazing paper and other materials by machinery. June 30

9632 T. B. Holmes and S. H. Holmes, Liverpool. A new or improved manufacture of pulp suitable for paper-making and for other purposes, and utilisation or treatment of a certain waste product or article of commerce therefor. July 8

9850 M. Strasser and P. Hosemann, London. An improved composition for coating pasteboard and other material to form writing tables. July 13

9919 E. A. Sengel and L. F. Dobler. An improved manufacture of gelatinised cloth or artificial parchment. July 15

10,006 G. R. Gill, London. The utilisation of paper, paper board, paper pulp or any of the preparations of which paper forms the base, for the manufacture of geometric models. Complete specification. July 16

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

5649 C. Barataud. Apparatus for reducing material for the manufacture of paper. July 2

7738 The British Xylonite Co., Limited, and L. P. Merriam. A novel xylonite celluloid or pyroxylin fabric suitable for making shirt fronts, collars, etc. June 29

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

8816 H. J. Simpson, G. de M. MacKirdy, and A. Taylor, Liverpool. A manufacture of tannins, gallates, kinos, and other vegetable extracts, from a certain tree, bark and wood, and treatment and process employed for obtaining such articles. June 18

9639 A. McDougall, London. New manufacture or preparation of compounds of sugar and tea extract or other extracts or essences. July 8

XXI.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

8929 H. Güttler, London. An improvement in the manufacture of charcoal for explosives and other purposes and apparatus therefor. June 22

8970 E. Grüne, London. Improvements in the manufacture of dynamite cartridges. June 23

9141 W. Hill, Longport. An improved safety blasting cartridge. June 28

9209 L. G. Heusschen, London. A new explosive. Complete specification. June 28

9502 H. C. Seddon, London. Improvements in percussion fuses for projectiles. July 5

9511 W. B. Fitch, London. An improvement in matches. July 5

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

11135 A. F. Hawksley. Means for lighting cigars, etc. June 29

11140 R. H. Punshon. Explosive compounds. July 2

11197 T. Nordenfelt. Fuses for projectiles. July 2

Printed and Published by Emmott & Co., New Bridge Street, Strangeways, Manchester, for the Society of Chemical Industry.
London Office, for the Sale of Copies and Receipt of Subscriptions: 6, York Street, Covent Garden.

THE JOURNAL
OF THE
Society of Chemical Industry:
A MONTHLY RECORD
FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 8.—Vol. VI.

AUGUST 31, 1887.

Non-Members 30/- per annum; Members 21/- per Set; Single Copies 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S. ..	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S. ..	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.

COUNCIL FOR YEAR ENDING JULY, 1888.

President: **Prof. James Dewar, F.R.S.**

Vice-Presidents:

Prof. F. Clowes, D.Sc.
Sir J. Neilson Cuthbertson.
David Howard.
Dr. Ferdinand Hurter.
Ivan Levinstein.
E. K. Muspratt.
Dr. W. H. Perkin, F.R.S.
Sir H. E. Roscoe, M.P., F.R.S.
John Spiller.
Prof. W. A. Tilden, F.R.S.
John Williams.
Philip J. Worsley.

Ordinary Members of Council:

John Calderwood, F.R.S.E.
Eustace Carey.
R. Forbes Carpenter.
James Duncan.
Dr. John Evans, F.R.S.
S. H. Johnson.
John Pattinson.
B. S. Proctor.
F. J. Rowan.
Dr. Edwd. Schunck, F.R.S.
T. W. Stuart.
Lewis T. Wright.

With Sixteen Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Ludwig Mond, 20, Avenue Road, Regent's Park, N.W.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

Sir F. A. Abel, F.R.S.
A. H. Allen.
H. E. Armstrong, F.R.S.
G. H. Bailey, Ph.D.
Joseph Bernays, M.I.C.E.
H. Brunner.
W. Lant Carpenter.
Prof. Frank Clowes, D.Sc.
W. Y. Dent.
Prof. Dewar, F.R.S.
Peter Griess, Ph.D., F.R.S.
D. B. Hewitt, M.D.
Prof. J. J. Hummel.
Prof. A. K. Huntington.
F. Hurter, Ph.D.
F. Jones, F.R.S.E.
Ivan Levinstein.
Prof. R. Meldola, F.R.S.
Ludwig Mond.
E. K. Muspratt.

NOTICES.

Comment having been made on the delay in reprinting the numbers for January, 1882 and 1883, the Secretary begs to inform those whom it may concern, that the delay is due to the fact that up to the present not more than twenty orders for those numbers have been received. It is hoped that this notification may stimulate those who desire to complete their sets, to make early application with a view to expedite the consideration of the question of reprinting by the Council. Notice is also hereby given that the numbers for January and February, 1886, being exhausted, no orders for those copies, nor for complete sets of Vol. V., can be executed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January, 1882 and 1883, at the following prices:—January, 1882, 5s.; January, 1883, 2s. 6d. Members possessing odd copies of these numbers are particularly requested to communicate at once with Mr. Cresswell.

Authors of communications read before the Society or any of its Local Sections are requested to take notice that, under Bye-Law 43, they cannot receive the prescribed 50 copies of their communications unless they comply with the condition laid down in that Bye-Law—viz., that they give notice of their desire to receive such copies upon their manuscript before sending it to the Editor. Mention should also be made as to whether the Discussion is to be included in the reprint.

CHANGES OF ADDRESS.

W. B. Andrew, l/o Duntocher; Gavinburn, Old Kilpatrick, Dumbartonshire.

G. H. Beckett, l/o Horton Lane; 37, St. Andrew's Place, Listerhills, Bradford, Yorks.

Bertram Blount; Journals, etc., to Chemical Laboratory, Broadway, Westminster, S.W.

F. G. Claudet, l/o Runcorn; c/o F. Claudet, 10, Oakhill Park, Hampstead, N.W.

R. L. Dale, l/o Cornbrook; 1, Chester Terrace, Chester Road, Manchester.

Robt. Davidson, l/o Greenock; Fiji Sugar Co., Samanoa, Navua River, Fiji.

T. J. Flynn, l/o Mitcham; 2, Dorset Villas, Herbert Road, Wimbledon, S.W.

J. W. Freestone, l/o New Ferry Road; 33, Brownlow Road, New Ferry, Cheshire.

A. J. Higgin, l/o Timperley; 5, Teneriffe Street, Higher Broughton, Manchester.

H. W. Langbeck, l/o Leman Street; The Cottage, St. Leonard's Street, Bromley by Bow, E.

J. Walter Leather; Journals, etc., to Royal Agricultural Society of England, 12, Hanover Square, W.

G. B. Nicoll, l/o Oregon; c/o Burnard, Lack and Alger, Plymouth, Devon, Thos. Owen, l/o Keynsham; Hazlehyrst, Cotham Park, Bristol.

R. Wightwick Roberts, l/o Valparaiso; retain Journals, etc., until further notice.

C. A. Serre, l/o New York; 140, High Street, Stoke Newington, N.

H. H. Slater, l/o Brading; 36, Wray Crescent, Tollington Park, N.

A. Trobridge; Journals, etc., to c/o Chance Bros., Alkali Works, Oldbury, Birmingham.

Wm. Upward, l/o Appleton; Albert Road, Widnes.

CHANGES OF ADDRESS REQUIRED.

Agnew Griffith, l/o 186, High Park Street, Liverpool.
T. R. Marshall, l/o Dachauer Strasse, Munich.
Eugen Wild, l/o Technikum, Winterthur, Switzerland.

LIST OF MEMBERS ELECTED, JULY 29, 1887.

J. Bingham Alliott, Messrs. Manlove, Alliott, Fryer and Co., Nottingham, mechanical engineer.

N. J. Bryce-Smith, Oakfield, Barrow, Whalley, near Blackburn, apprentice, calico printing.

W. L. Dudley, Vanderbilt University, Nashville, Tenn., U.S.A., professor of chemistry.

Frederick Foster, Niagara Works, Eagle Wharf Road, London, N., engineer and manufacturing chemist.

Charles J. P. Fuller, Laboratory, Lancashire and Yorkshire Railway, Horwich, near Bolton, analytical chemist.

James N. Gamble, Messrs. Procter and Gamble, Cincinnati, Ohio, U.S.A., soap and oil manufacturer.

Harry Gibbs, 73, Horton Lane, Bradford, Yorkshire, manufacturing chemist.

Richard Haig-Brown, jun., Seymour Terrace, Old Trafford, Manchester, storekeeper, M. S. and L. Railway.

Ernest A. Hellier, 34, Brunswick Avenue, Beverley Road, Hull, varnish maker.

Edwin Higginbottom, Oakfield House, Barrow, Whalley, near Blackburn, printworks manager.

John F. Ingleby, 5, Carlton Terrace, Spring Bank, Hull, oil boiler and refiner.

Frederick C. Jenkins, 21, Heber Road, East Dulwich, S.E., analytical chemist.

Walter S. Jessop, Healey, Ossett, near Wakefield, manufacturer and dyer.

T. Tolley Jones, 31, Little Collins Street East, Melbourne, Victoria, manufacturer of nitro-glycerine and acids.

Samuel Lees, jun., Park Bridge, Ashton-under-Lyne, chemist.

J. Francis Mason, Eynsham Hall, Witney, Oxon.

Edwin B. Morgan, 318, Nechells Park Road, Birmingham, chemical manufacturer.

John M. C. Paton, Messrs. Manlove, Alliott, Fryer and Co., Nottingham, mechanical engineer.

Thomas Scattergood, 22, North Front Street, Philadelphia, Pa., U.S.A., drysalter.

Thomas Stenhouse, 1, Milton Street, Rochdale, public analyst for Rochdale.

James Stuart, Prince's Avenue, Hull, seed crusher and oil refiner.

James Sutherland, Ballyclare, Co. Antrim, Ireland, chemist to paper mills.

G. W. A. Teanby, 22, Grosvenor Place, Blackman Lane, Leeds, student.

Frederick Percy Watson, 31, Carholme Road, Lincoln, analyst and pharmacist.

John Campbell White, 7, West George Street, Glasgow, chemical manufacturer.

London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: David Howard.

Committee:

Sir F. A. Abel.
H. E. Armstrong.
W. Lant Carpenter.
W. Crowder.
W. J. Dibdin.

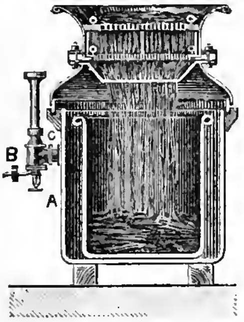
Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS AND MACHINERY.

Körting's Steamjet Aspirator for the Filtration of Viscid Liquids. Chem. Zeit. **11**, 510.

The action of the apparatus is based on the production of a vacuum below the filter. Fig. 1 shows the essential parts of an apparatus, A being the filtering vessel, B the steam-aspirator, and C the suction pipe.—S. H.



Apparatus for Drying Waste Animal Matter and for like Uses. J. S. Edwards and J. Edwards, Eastbourne. Eng. Pat. 6306, May 10, 1886. 11d.

The apparatus consists of a short cylinder provided with a hollow steam-heated bottom. The upper part is covered with a conical dome provided with a lip at the lower part which catches and drains away the condensed steam. The interior of the cylinder is provided with a revolving mechanical agitator and also fixed blades for the agitation of the material during the operation.
—C. C. H.

Improvements in Filter Presses and in Apparatus connected therewith. J. B. Alliott and J. M. C. Paton, Nottingham. Eng. Pat. 7045, May 26, 1886. 8d.

The central screw which is usually employed to press the plates of the filter press together, is replaced by a double acting hydraulic piston or ram. Low-pressure water is used to force into place or withdraw the loose head or follower of the press, and high-pressure water is used afterwards for holding the plates tight against the pressure in the press. The high pressure may be applied either by a pump, a screw plunger or a weighted accumulator. The second portion of the specification describes an improved "clip nut" for securing the cloths on the plate round the central orifice which forms the communication between chamber and chamber.
—C. C. H.

Improvements in Apparatus for Separating Impurities or Objectionable Matter from Solids. S. Vickess, Liverpool. Eng. Pat. 8905, July 8, 1886. 1s. 1d.

For the removal of the matter separated by filtration of a liquid from the filtering body, in order that it may be re-used, the patentee describes a form of apparatus, which consists essentially of a revolving cylindrical vessel, the internal periphery of which is provided with curved or screw shaped projections; passing through the centre of the cylinder is a rotating continuous archimedian screw of opposite pitch to the projections in the cylinder. This combination serves to ensure the passage of the material through the apparatus in a contrary direction to a current of water which is intended to carry away the impurities. The washed material is delivered into one of a series of vertical receivers where some of the excess washing water drains away.—C. C. H.

Improvements in Apparatus for Filtering Liquids. S. Vickess, Liverpool. Eng. Pat. 10,370, July 8, 1886. 1s. 1d.

The improved apparatus is applicable to the treatment of large quantities of liquid such as water in a water works. It consists of an arrangement of tanks so contrived that the liquid treated is filtered by upward filtration through a bed of filtering material arranged to lie on a sloping surface. Apparatus and appliances for the removal and washing of the filtering medium are also described. The various details are shown on five sheets of drawings.
—C. C. H.

Improvements in Filtering Machines. J. A. Crocker, New York, U.S.A. Eng. Pat. 2710, Feb. 22, 1887. 8d.

The improved filtering machine consists of a cylindrical wrought-iron vessel, capable of rotation on its axis, placed horizontally, provided with a hollow inlet trunnion and a similar outlet trunnion at the opposite end. The periphery of the cylinder is provided with corrugated, curved or cylindrical strainers, through which the water must pass before passing through the filtering material, which may be of charcoal or any similar material. The current can be reversed by the revolution of the whole apparatus, the water then entering the machine by the perforated pipe and corrugated sheet by which previously it had left the apparatus after filtration, and *vice versâ.*
—C. C. H.

Improvements in Filtering Machines. J. A. Crocker, New York, U.S.A. Eng. Pat. 2711, Feb. 22, 1887. 8d.

This specification describes improvements on former similar apparatus patented by the author, and refers to that description of filter described in Eng. Pat. 2710. The reversal of the current of water in the improved machine is effected by a gravity valve, which falls and so reverses the current of water passing through the apparatus, in place of the coincidence of parts and passages in the hollow journals upon which the machine is rotated.—C. C. H.

Improvements in Decantation Apparatus for Clarifying and Purifying Water and other Liquids. J. Y. Johnson, London. From La Société G. Boone et J. Nery, Paris. Eng. Pat. 2766, Feb. 22, 1887. 8d.

This apparatus is somewhat similar to those already known as "Subsidence" apparatus, and is intended to separate solid matter from the liquid in which it is suspended without filtration. The apparatus consists of a vessel, shown in adjoining figure, divided into three portions—A, B and C. Water or other liquid to be

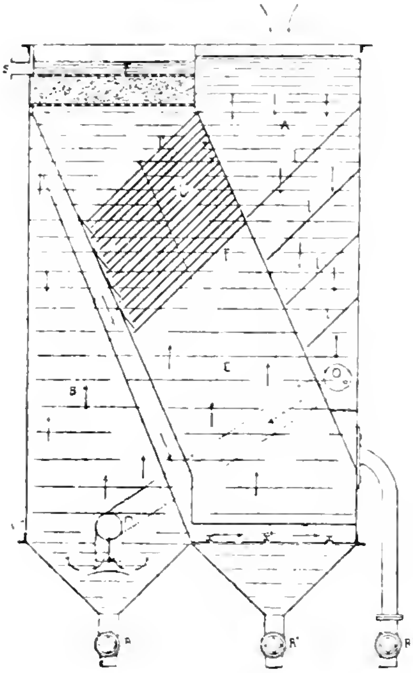
---

* Any of these specifications may be obtained by post, by remitting the cost price, *plus* postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.........	½d.
Above 8d., and not exceeding 1s. 6d...	1d.
„ 1s. 6d., „ „ 2s. 4d...	1½d.
„ 2s. 4d., „ „ 3s. 4d...	2d.

clarified enters at the upper part of A: some of the solid matter deposits on the sloping shelves *b*, down which it slides into the bottom of A, and is periodically removed through valve R. The pipe *o* conducts the liquid from A to B, where in its ascension further subsidence occurs. It finally enters at the bottom of C through the perforated pipe or pipes *x*; ascension through the sloping shelves *b''* causes more of the solid matter to be removed, as described in the case of A. R and R' serve for the periodic removal of the subsided matter. F is a filter formed of any porous material sufficiently fine to remove the last traces of the suspended matter still remaining in the liquid.—C. C. H.

FIG 1



II.—FUEL, GAS AND LIGHT.

Improvements in Means for Utilising Oils or Gases as Fuel and for Lighting Fires. W. Welch, Portsmouth. Eng. Pat. 9658, July 27, 1886. 4d.

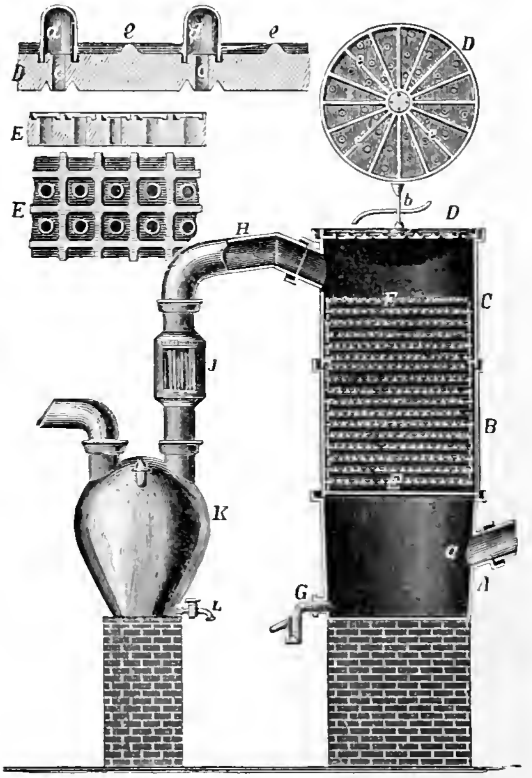
A METAL or fireproof porcelain box, small enough to pass between the bars of an ordinary grate, is employed with a pipe admitting oil or gas to its lower portion. This lower portion is packed with some porous or granular material, which is covered with a perforated fireproof lid. The oil or gas percolates through the porous medium and, burning upon the perforated surface, kindles the coal or other fuel in the grate. The supply of oil or gas is, of course, controlled by a tap.
—A. R. D.

Improvements relating to the Production of Light by the Incandescence of Refractory Materials. F. L. Rawson and W. S. Rawson, London. Eng. Pat. 11,161, Sept. 1, 1886. 8d.

THE patentees stretch the mantles upon a mandril of platinum foil and ignite them with a blow-pipe flame. By this means a great regularity of shape is secured and the mantles when brought into use may be raised to their full efficiency at once. Otherwise they require four or five hours' burning over the ordinary Bunsen flame to produce full incandescence. To diminish risk of breakage in transport the mantles are dipped in a hot liquid hydrocarbon, preferably a paraffin of high boiling point, such as ozokerit. The paraffin is soon burned away when the mantle is used. The improvements include various details concerning the suspension of the mantle and arrangement of burner and chimney.
—A. R. D.

Absorption Apparatus for the Condensation of Gases and Vapours by Liquids. Lunge and Rohrmann. Chem. Zeit. 11, 693.

THE apparatus consists of the dish A, which is the bottom of the absorbing column B, and the top D. The cooled gases enter at the bottom through *a* and thence rise into the cylinder, where they meet a descending stream of liquor, which is equally distributed over the top by the turbine *b*. Lutes *d* and holes *e* form a passage for the liquor into the interior, which consists of a large number of horizontal shelves. Raised divisions divide each shelf in a large number of squares, each of which is provided with a hole, through which the liquor flows to the lower shelf. The diagram shows the peculiar construction of the squares and holes, which has the effect of compelling a layer of liquor to stand on each square, thus exposing an immense surface to the ascending gases. The shelves are arranged in such a manner that each hole is above the junction point of four squares in the next lower shelf. The descending liquid drops on this point, is splashed about and collects on the adjoining squares, renewing its surface continually. G is the outlet pipe for the saturated liquor. The "shelf-tower," as the apparatus is termed, claims to be far more effective than the absorbing columns of the usual construction.—S. H.



An Improved Magnesium Light for Photographic Purposes. J. Gaedicke, Berlin, and A. Miethe, Potsdam, Germany. Eng. Pat. 7035, May 13, 1887. 6d.

IT is proposed that the magnesium be mixed in the state of fine powder with an oxidising agent, such as a chlorate or nitrate, and a substance such as amorphous phosphorus, which would accelerate combustion. The mixtures suggested as most suitable are—12 parts of chlorate of potash, six parts of magnesium powder and one part of prussiate of potash, or 24 parts of chlorate of potash, 12 parts of magnesium powder and one part of amorphous phosphorus. The light may be coloured by the addition of salts of suitable metals to the above mixtures. The powder burns with a flash, lasting only from $\frac{1}{30}$ to $\frac{1}{50}$ of a second, and yields a more intense light than when wire or ribbon is used; and the shortness of its duration removes the difficulty hitherto experienced of getting the proper "exposure" with the magnesium light.—A. R. D.

Regenerative Gas Lamps. F. Siemens, London. Eng. Pat. 7610, May 25, 1887. 6d.

A HORIZONTAL gas flame burns in a transparent or translucent globe. Above the flame is a perforated reflector which forms the bottom of a kind of flattened chamber connected with a casing round the base of the chimney. By suitable apertures air enters this casing and travels through the flattened chamber, whence part of it passes through the perforated reflector to the upper surface of the flame, and part finds its way by another channel into the globe space and supplies the under side. The products of combustion pass upward into a cavity above the flattened chamber, and thence through a perforated top to the chimney. It will be seen that the flattened chamber is kept hot by the flame below it, and the passage of the products of combustion above. Moreover, the air before entering here has been already heated by contact with the chimney base. The lamp is started by a small gas jet, which is lighted from the outside through one of the air apertures. This renders it unnecessary to remove the globe when lighting up, as the main jet ignites from the smaller one, which may then be extinguished.—A. R. D.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Notes from Baku. Chem. Zeit. **11**, 476.

It has been decided to lay pipes from Baku to the Caspian Sea, for the purpose of conveying both kerosene and naphtha. There can be no doubt that as a result of this, a considerable quantity of naphtha residues, which hitherto were wasted, will be utilised.

A patent has been recently taken by G. Tergmanowski for the production of naphtha gas, which is made in a generator, identical with those used for gas-firing in metallurgical and glass works. Gas is produced from wood, turf or coal, and is employed for igniting lime in the so-called "lime furnace," and on this ignited lime, crude naphtha is poured and steam passed over it at the same time. The evolved gas is chiefly composed of hydrogen, mixed with small proportions of other combustible gases and carbonic acid. It is passed through a condenser and thence into the gasometer. After being purified by the lime process it enters if necessary the carburetter. Another portion of the gas from the generator is used for decomposing some naphtha, but without the aid of steam. The product consists chiefly of olefines, which in conjunction with that from the lime furnace gives a constant illuminating gas.—A. R.

The Baku Petroleum Industry. Chem. Zeit. **11**, 605.

A CONSIDERABLE rise in prices has been caused by the combined action of some of the more important companies interested in this industry. The Caspian and Black Sea Association (*i.e.*, the Rothschilds') has made an arrangement with most of the smaller firms according to which they are for the next five or six years to sell their distillates exclusively to this Association, and at a fixed price. At present the yield of naphtha is small, and the oil is only obtained at considerable depths (210 to 255 metres). Some firms, seeing that the Baku supply must be exhausted sooner or later, have been looking out for new naphtha districts and have already purchased land near Elisabethpol and Tiflis. The richest oil fields in the Trans-Caucasus lie between Tiflis, the province of Kakhetien, and the valley of the river Kura. Naphtha is found close to Tiflis, on the banks of the Kura, and also near Elisabethpol, about 15 kilometres from the railway. Geological investigations of the Trans-Caucasian provinces have only been carried out in a few places, and there very superficially. The country contains an abundance of valuable minerals and offers an inviting field for energetic capitalists, of whom, unfortunately, there appear to be few in Russia.—D. E. J.

Notes on the Analysis of Commercial Benzene. C. Häussermann. Chem. Zeit. **11**, 803.

It is the custom at some works to ascertain the quantity of olefines in commercial benzol by the titration of the latter with bromine. This process may easily cause mistakes, since the power of rapidly absorbing bromine depends principally upon the presence of pyridine, pyrrol and members of the thiophen group and also upon occasional olefines. So that a benzene from which these impurities have been removed by treatment with sulphuric acid may have completely lost the property of decolorising bromine water, and still contain valueless hydrocarbons. The author frequently detected as a companion of commercial toluene a hydrocarbon, or a mixture of several hydrocarbons, which was not acted upon by bromine and resisted nitrification. It was separated during the process of nitrifying toluene on the large scale, and forms a colourless liquid of sp. gr. 0·728, boiling between 119° C. and 124° C. It is not dissolved by sulphuric acid, and consists probably of a member of the paraffin group (octane?). The test with bromine is therefore only a test for the more or less complete treatment with sulphuric acid.—S. H.

Presence of Fatty Acids in Light Resin Oil. J. Lwoff. Ber. **20**, 1017—1023.

It has already been shown by Kelbe (*Ber.* **13**, 1157; and **15**, 308) that from the lower boiling fractions of resin oil, a number of acids of the general formula $C_nH_{2n}O_2$ can be extracted by means of caustic soda, amongst which are isobutyric and caproic acids. Kelbe and Warth subsequently showed that the caproic acid of resin oil was methyl-propylacetic acid. In addition to these acids the author has succeeded in extracting valeric and œnanthylic acids from the acid mixture obtained by treating light resin oil with soda.—D. B.

Pyrogenic Reactions. P. Ferko. Ber. **20**, 660—664.

The experiments were made in an iron tube 60cm. long, and 4cm. in diameter, which was heated in a Mermet's gas furnace. Washed and well-dried ethylene gas was passed through gently-boiling benzene and then through the tube until 1·5 litres of benzene were used, a process which occupied seven hours. A brownish black distillate was obtained, commencing to boil at 80°, from which the following compounds were separated by fractional distillation:—Unchanged benzene 80grms., cinnamene (styrol) 17grms., diphenyl 300grms., phenanthrene 10grms., and anthracene 15grms. The absence of naphthalene and acenaphthene is explained by the fact that in these experiments a lower temperature was used than in the case of the trials made by Berthelot.

From toluene *per se* (1·5 litres), the following products were obtained:—Benzene 150grms., toluene 180grms., cinnamene 7grms., naphthalene 40grms., diphenyl 27grms., a yellow oil, boiling at 270—280°, 10grms., phenanthrene 1·5grms., and anthracene 12grms. When toluene and ethylene are passed through the tube, the following hydrocarbons are obtained, 1·25 litres of toluene being used:—Benzene 200grms., toluene 160grms., cinnamene 10grms., naphthalene 35grms., an oil boiling between 270—280° 13grms., and anthracene 20grms.

Naphthalene alone (850grms.) yielded 470grms. of unchanged naphthalene and 130grms. of dinaphthyl. Naphthalene (900grms.) and ethylene gave 400grms. of unchanged naphthalene, 0·5grm. of acenaphthene, 1grm. of phenanthrene and 125grms. of dinaphthyl; no anthracene was formed.

Ethyl-benzene (500grms.) yielded 75grms. of benzene, 5grms. of toluene, 20grms. of unchanged ethylbenzene, 10grms. of cinnamene, 11grms. of naphthalene, 3grms. of diphenyl, 13grms. of phenanthrene and 2grms. of anthracene.

Azobenzene yielded only small quantities of benzene and diphenyl, no anthracene or chrysene being formed, although in the trials made by Claus (*Ber.* 8, 37) these hydrocarbons are said to have been isolated.—D. B.

Pentamethylbenzene. O. Jacobsen. Ber. **20**, 896—902.

THE author has prepared this compound by treating trimethylbenzene with methylchloride at 100—110° in the presence of aluminium chloride, cooling the product, pressing it and subjecting it to fractional distillation. The portion boiling between 220° and 235° was then dissolved in hot alcohol; hexamethylbenzene crystallised out on cooling, whilst the mother-liquor contained the penta-compound. The latter was purified by conversion into its sulphone and sulphamide derivatives and subsequent treatment with hydrochloric acid. *Pentamethylbenzene* $C_6H(CH_3)_5$ forms large flat prisms melting at 51·5° and boiling at 231°. It is readily soluble in alcohol. The picrate crystallises from alcohol in golden yellow prisms melting at 131°. The bromo-derivative $C_6Br(CH_3)_5$ forms nacreous rhombic leaflets melting at 163° and boiling at 292°. It dissolves readily in ether, but is only sparingly soluble in alcohol. The sodium and potassium salts of the sulphonic acid are insoluble in cold and sparingly soluble in hot water. The barium salt forms small plates sparingly soluble in hot water. The calcium salt crystallises in large nacreous scales; the silver salt in small lustrous plates. The copper salt forms thin hexagonal greenish white tablets, which are almost insoluble in water. The sulphonic chloride dissolves readily in alcohol and ether. It crystallises from the latter in large, well-defined flat prisms melting at 82°. The sulphamide forms large, flat prisms, having a vitreous lustre and melting at 186°. Pentamethylbenzenesulphone $C_6(CH_3)_5.SO_2.C_6(CH_3)_5$ crystallises from warm petroleum spirit or dilute alcohol in long, fine, colourless needles melting at 98·5°. It is readily soluble in alcohol. By the action of cold concentrated sulphuric acid on pentamethylbenzene, hexamethylbenzene and prehnitene and the sulphonic acids of the latter are obtained.—D. B.

Preparation of Primary and Secondary Xylylamines from Xylenols. P. Müller. Ber. **20** 1039—1042.

ON heating β-orthoxylenol with zinc-ammonium bromide and ammonium bromide in the proportion of 1:3:1, the following compounds are obtained:—

EXPERIMENTS—	I.	II.	III.	
Xylidine	27·5	25·5	26·0	per cent.
Dixylylamine	50·0	48·0	20·0	,,
Carbonaceous matter	4·0	4·0	17·0	,,
Unchanged Xylenol	—	16·5	30·5	,,

In experiments I. and II. the temperature was kept for 40 hours at 310—320°, whilst in experiment III. the mass was heated for 20 hours at 330—340°.

On heating α-metaxylenol under similar conditions the following results were obtained:—

	I.	II.	
α-Metaxylidine	39·0	40·0	per cent.
Di-α-metaxylylamine	19·5	12·5	,,
Carbonaceous matter	3·5	4·5	,,
Unchanged Xylenol	34·0	32·5	,,

In No. I. the temperature was kept for 40 hours at 310—320°, and in No. II. the temperature ranged from 330—340°.
—D. B.

Improvements in the Manufacture of Benzene, Anthracene, Naphthalene and other Products from Naphtha and Naphtha Residues. A. Nikiforoff, Chimka, Russia. Eng. Pat. 10,957, August 27, 1886. 6d.

THE inventor claims the production of benzene and other aromatic hydrocarbons from naphtha and naphtha residues (presumably petroleum residues) by first slowly decomposing the naphtha in cylindrical retorts at a low temperature, the object being to obtain as large a quantity as possible of hydrocarbons boiling below 200° and having a sp. gr. of about 0·800 to 0·810, and then submitting the hydrocarbons to a second distillation, by which they are transformed into hydrocarbons of the aromatic series, C_nH_{2n-6}, anthracene and naphthalene being obtained from the residue. The second distillation can be effected in cylindrical or in other shaped retorts, and it has been found that the best result is obtained by dividing the hydrocarbons for redistillation in two parts—viz., those boiling at from 0° to 140° and higher, and then to redistil them again separately. The following results are usually obtained:—About 12 per cent. of benzene and its homologues, sp. gr. 0·870, boiling at 80—135°, 0·5 per cent. of anthracene, 2 per cent. of naphthalene, 5 per cent. of coke, and a residue consisting of a mixture of different hydrocarbons, some of which can be used for the manufacture of lubricating oils.

The invention "is based on the theory of producing, firstly, easily transformable hydrocarbons with a grouping of elements capable of being transformed into a more solid group—viz., into the aromatic group. These hydrocarbons, at the pressure and temperature obtained by a second distillation of the tar boiling at from 0° to 200°, produce benzene, from which aniline oil can be prepared." Hitherto it has not been possible to produce benzene commercially from naphtha, though it has been proposed to produce it in retorts charged with coke, copper filings or platinised coke; but as each charging of the retorts, besides increasing the cost of the production, is quite impracticable, owing to the stopping-up of the retorts, such method of producing benzene has not been successful. In the second distilling process, as above described, the coke detaches itself in the retorts, which, up to the present, has not occurred in the distillation of naphtha for gas.—D. B.

Improvements in Retorts for the Destructive Distillation of Shale, Coal and other Bituminous Substances. J. Jones, Dalmeny, N.B. Eng. Pat. 11,134, Sept. 1, 1886. 8d.

IN constructing vertical retorts for the destructive distillation of coal the common practice is to set them in two rows, with their backs disposed towards each other, and the discharge mouths projecting outwards at the bottom of each retort. In retorts thus constructed hindrance to their efficient working is caused by the clinker collecting as a hard mass at the back of the retort. In the present invention the parts to which the clinker usually adheres, forming the backs of a pair of retorts, are removed, and the lower part of each pair thereof is thus constituted into a chamber common to the upper parts of the two retorts. It is stated that this mode of construction is applicable both to the setting of new retorts as well as to the alteration of existing retorts.—D. B.

IV.—COLOURING MATTERS AND DYES.

Contributions to the Knowledge of Hydroxyanthraquinone Colouring Matters. C. Liebermann and W. Wense. Ber. **20**, 862—866.

IT has been shown by Liebermann and Kostanecki that only those hydroxyanthraquinones possess tinctorial properties which contain the hydroxyl groups in the alizarin position. In order to obtain evidence in confirmation of this view a compound which is an alizarin and a quinazarin simultaneously has been prepared from hemipinic acid by condensation with quinol in the presence of concentrated sulphuric acid. The mass thus obtained crystallises in microscopic leaflets of brown-red colour melting at 225—230°, and having the constitution $C_6H_2(OCH_3)_2 < \genfrac{}{}{0pt}{}{CO}{CO} > C_6H_2(OH)_2$. It is, therefore, a *dimethyl ether of quinalizarin.* It dissolves readily in hot glacial acetic acid, less readily in hot alcohol or benzene. Alkalis dissolve it with a violet colour, whilst concentrated sulphuric acid gives a blue solution. With mordants it gives but a faint colour reaction. The acetyl compound crystallises in small needles melting at 210–211°. It is almost insoluble in cold alcohol, acetone, or petroleum spirit, but more readily soluble in hot solvent. *Quinalizarin* $C_6H_2(OH)_2 < \substack{CO \\ CO} > C_6H_2(OH)_2$ is obtained by heating its dimethyl ether with hydrochloric acid at 200° for 3—4 hours. It crystallises in long deep red needles which are more insoluble than the dimethyl ether, hot glacial acetic acid being the best solvent. Its reactions with alkalis and concentrated sulphuric acid are similar to those of the dimethyl ether; its barium and calcium salts are insoluble in water. It sublimes in dark-red needles, but exhibits no sign of fusion at 275°. On distillation with zinc dust anthracene is obtained. It possesses strong tinctorial properties resembling those of cochineal. The *tetracetyl* compound $C_{14}H_4(OC_2H_3O)_4O_2$ crystallises in needles melting at 201°.—D. B.

Trimethylanthragallol. H. Wende. Ber. **20**, 867—870.

ψ-CUMIDINE, when converted by Sandmeyer's method into duryl-cyanide (duronitrile) yielded only 15 per cent. of the theoretical quantity. The nitrile was converted by heating with HCl into durylic acid. Three parts of durylic acid, 2 parts of gallic acid and 30 parts of strong sulphuric acid were gradually heated from 70—115° during 8 hours, and then kept at 120° until a sample showed the absence of durylic acid. The sulphuric acid was removed from the melt by precipitating and washing with water, and the trimethylanthragallol was extracted first with alcohol and then finally with benzene, leaving a residue of rufigallic acid. *Trimethylanthragallol* $C_{14}H_2(CH_3)_3.O_2.(OH)_3[(CH_3)_3:(OH)_3=1:3:4:1':2':3']$ crystallises from dilute alcohol in brilliant brown needles, melting at 244°, readily soluble in alcohol and glacial acetic acid, less soluble in benzene; it dissolves in strong sulphuric acid with a red-violet, in potash with a green, and in ammonia with a violet colouration. Its absorption spectrum and dyeing properties are similar to those of anthragallol. Its triacetyl-derivative $C_{14}H_2(CH_3)_3.O_2.(OC_2H_3O)_3$ forms pale yellow rhombic tables, melting at 174°. When distilled over zinc-dust trimethylanthragallol yields a solid hydrocarbon, melting at 236° —probably the trimethylanthracene of Gresly—and an oily substance which the author considers to be a hydride of trimethylanthracene.—T. L. B.

Dimethylanthragallol. W. Birukoff. Ber. **20**, 870—873.

WHEN gallic acid (3 parts) is condensed with metaxylic acid (5 parts) by means of sulphuric acid (40 parts) *dimethylanthragallol* $C_{14}H_3(CH_3)_2O_2(OH)_3[(CH_3)_2:(OH)_3=1:2:1':2':3']$ is obtained. After heating the above mixture for 20 hours at 70—120°, the melt is poured into water and the sulphuric acid washed away. The precipitate is extracted with absolute alcohol, which leaves undissolved the rufigallic acid formed. The alcohol is evaporated, and the dimethylanthragallol is extracted by benzene from the residue. The yield is only about 2 per cent. on the xylic acid used. This body crystallises in yellowish-red needles, and is similar in its absorption-spectrum and behaviour with alkalis to anthragallol. On distilling over zinc-dust, it yields a solid hydrocarbon, probably a dimethylanthracene, melting at 220—226°, the quinone obtained from this melting at about 112°. The isomeric compounds obtained by Gresly melted at 202° and 180° respectively. The author recommends the following methods for obtaining the metaxylic acid. Pure metaxylidine is prepared from commercial xylidine by Limbach's method:—4 parts of xylidine are mixed with 1 part of glacial acetic acid, and allowed to stand for 24 hours; the crystals of the acetate of metaxylidine are then pressed free from the paraxylidine, which remains in solution, basified, dried and distilled. The meta-compound is converted by Sandmeyer's method into the nitrile. 12grms. of this product are dissolved in 8grms. of water and 20grms. of HCl, and 7grms. of sodium nitrite dissolved in 20grms. of water slowly added. This diazo-solution is poured in a thin stream into the copper cyanide solution warmed to 90°. The yield of cyanide of metaxylene (metaxylonitrile) is 50—60 per cent. of the theoretical. By gently warming the nitrile with about 85 per cent. sulphuric acid, it is converted into the amido-acid, and this, by heating for two hours at 170° with HCl, yields about 60 per cent. of metaxylic acid.—T. L. B.

Opiaurin. C. Liebermann and P. Seidler. Ber. **20**, 873—874.

OPIANIC ACID and phenol, when heated together with strong sulphuric acid, give rise to an intense yellow-red dye. The reaction takes place between the aldehyde-group of the acid and the phenol:—$C_6H_2(OCH_3)_2(CO_2H)(COH) + 2C_6H_5.OH = H_2O + C_6H_2(OCH_3)_2.(CO_2H).CH:(C_6H_4OH)_2$. This compound *leucopiaurin* is oxidised during the process to opiaurin $C_{22}H_{18}O_6$. The best results were obtained by stirring an intimate mixture of opianic acid and phenol into sulphuric acid (60° Bé.) and keeping the mixture well cooled. After 24 hours' rest the melt was thrown into a large quantity of cold water, and the precipitate when washed and dried, freed from tarry matters by extraction with hot benzene. Opiaurin is soluble in alcohol, ether and glacial acetic acid, insoluble in benzene and petroleum ether. It could only be obtained in amorphous condition. It dissolves in alkalis with a purple colour; the solution in alcoholic ammonia becomes on heating brownish-yellow, but the purple colour returns on cooling.

Sulphurous acid does not reduce it. Opianic acid reacts in a similar way with other phenols, and the reaction can be used to detect the presence of opianic acid, as also of an aldehyde-group in aromatic compounds; the reagents being each dissolved in an excess of cold sulphuric acid, on mixing the solutions the coloration takes place at once.—T. L. B.

Preparation of β-Nitronaphthalene. E. Lellmann. Ber. **20**, 891—893.

THE following is a modification of the method originally employed for the preparation of this compound. The mixture of *o*- and *p*-nitroacetonaphthalide is obtained as in the old process, the product is then boiled with a 14 per cent. solution of caustic potash in the presence of alcohol and the resultant mass consisting of the *o*-aceto-compound and *p*-nitronaphthalene is treated with ethyl-nitrite. A brown precipitate is obtained which was found to contain the diazoamido-derivative of *p*-nitronaphthylamine. This is filtered off as quickly as possible so that the *o*-nitroacetonaphthalide crystallises out in the filtrate. It is purified by recrystallisation and filtration through animal charcoal and is decomposed by the addition of an alcoholic solution of hydrochloric acid. The *o*-nitronaphthylamine thus obtained forms small red needles melting at 143° and is suitable for the preparation of β-nitronaphthalene.—D. B.

An Universal Reaction of Diazo-amido Bodies. K. Heumann and L. Oeconomides. Ber. **20**, 904—909.

THIS reaction takes place when diazo-amido bodies are brought in contact with phenols, one of their basic constituents being regenerated, the phenol taking its place and forming oxyazo compounds. Thus on heating gently diazoamidobenzene with resorcinol, aniline is regenerated and benzeneazoresorcinol, melting at 161°, formed: $C_6H_5N=N.NH.C_6H_5 + C_6H_4(OH)_2 = C_6H_5.NH_2 + C_6H_5.N=N.C_6H_3(OH)_2$. Diazo-amidoparatoluene treated with phenol yields paratoluidine and paratolueneazophenol $C_7H_7N=N.C_6H_4OH$; with resorcinol, the same base and paratolueneazoresorcinol $C_7H_7N=NC_6H_3(OH)_2$, which forms yellowish-red needles melting at 184°. A monochloro-oxyazobenzene was obtained by acting on diazoamidoparachlorobenzene with phenol; it forms red-yellow needles melting at 151—152°. In a similar manner, diazoamidometabenzoic acid is converted into benzoic-acid-azophenol melting at 220°. The author found that the diazo-amido bodies obtained by diazotising aniline and combining with paratoluidine, or *vice versâ*, and considered to be identical, give rise with phenol, to mixed oxyazo bodies, a mixture of about equal parts of aniline and paratoluidine being regenerated. Diazoamidoparachlorobenzene-benzene, obtained by diazotising parachloraniline and combining with aniline, yielded parachloraniline and oxyazobenzene. This reaction can be readily illustrated in a lecture experiment, by warming some diazoamidobenzene with a little phenol in a test tube for a few moments, when on the addition of caustic soda solution the oxyazo body formed will dissolve, and can be thrown down on the addition of an acid.

—T. L. B.

A New Chromogenic Body—Phenazoxin. A. Bernthsen. Ber. 20, 942—944.

RIS has shown that phenazine may be obtained by the action of *o*-phenylenediamine upon catechol. By the action of *o*-amidophenol upon catechol, phenazoxin may be prepared, thus:—

$$C_6H_4\left\langle{}^{OH}_{OH}\right. + {}^{NH_2}_{OH}\!\left.\right\rangle C_6H_4 = C_6H_4\left\langle{}^{NH}_{O}\right\rangle C_6H_4 + 2H_2O$$

Equal weights of *o*-amidophenol and catechol are heated in closed tubes for 40 hours to 260—280°. The product is extracted repeatedly with water and caustic soda solution, and the residue with ether. The ethereal solution on distillation leaves a solid brownish residue which, on recrystallisation from alcohol, yields a colourless crystalline product. The analysis corresponds to the formula $C_{12}H_9NO$. Phenazoxin may be readily nitrated, and the nitro product on reduction with Sn and HCl, and subsequent oxidation with Fe_2Cl_6 gives a red-violet colouring matter. This reaction corresponds to the formation of Lauth's violet from thio-diphenylamine, and confirms the chromogenic character of phenazoxin.

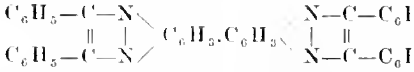
—J. B. C.

m-(αβ¹)-Naphthylene Diamine. C. Urban. Ber. 20, 973—974.

LIEBERMANN and Hammerschlag prepared a dinitronaphthylamine with the amido and nitro-groups in one nucleus, the former and one of the nitro-groups in the α, the other being in the β position. Worms showed that the latter group occupies an adjacent position to the amido-group, and the compound has, therefore, the formula—$C_{10}H_5.NH_2(NO_2)_2.[NH_2 : NO_2 : NO_2 — 1 : 2 : 4.]$ By eliminating the amido-group a dinitronaphthalene should be obtained with the nitro-group in the meta-position. On reducing the dinitro-compound, a meta-diamido compound is obtained, which yields with nitrous acid the deep yellow colour characteristic of meta-diamines, and further a precipitate of the corresponding chrysoidine with diazo-benzene sulphonic acid.—J. B. C.

Some Derivatives of Benzidene. P. Brunner and Otto N. Witt. Ber. 20, 1023—1030.

THE authors recommend the following method for obtaining the orthodinitrobenzidine of Strakosch: 10grms. of diacetylbenzidine are stirred into 100grms. of nitric acid (sp. gr. 1·48) kept cool with ice, and then ice and water added until the dinitrodiacetylbenzidine is precipitated. From this body the acetyl groups are readily removed by warming with 1½ parts of caustic potash and a little alcohol, the dinitrobenzidine precipitating in the form of fine red needles. It is insoluble in water, soluble with difficulty in alcohol, more readily soluble in phenol. When it is ground up with the proper quantity of stannous chloride, HCl added, and the mixture warmed on the water-bath until all dissolves in water, it is reduced to a *tetramidodiphenyl*: $C_{12}H_6(NH_2)_4$. The hydrochloride of this base forms needles containing $2H_2O$, readily soluble in water, less soluble in HCl. The basic sulphate $C_{12}H_6(NH_2)_4H_2SO_4$ is very slightly soluble in cold water, alcohol and ether, soluble in hot water. The base precipitates on the addition of ammonia to a solution of the hydrochloride, forming small silvery plates soluble in hot water, but which decomposed so readily that they could not be analysed. The dry hydrochloride gives Ladenburg's reaction with benzaldehyde; with sodium nitrite, a crystallised azimido compound is formed. The platinum double salt forms needles which quickly decompose. Ferrous chloride gives a brown colour reaction. Tetramidodiphenyl condenses with phenanthrenequinone, forming a brownish-yellow azine, subliming in yellow needles, which dissolve in H_2SO_4 with a violet colour. With isatine a yellow-orange, and with β-naphthoquinone a brown gelatinous compound is formed. On mixing glacial acetic acid solutions of this base and benzil together, a pale yellow azine $C_{10}H_{26}N_4$ precipitates. It does not melt at 270° and decomposes when heated higher. It is very soluble in phenol. Its sulphate forms lemon yellow needles, dissolving in strong H_2SO_4 with a fine magenta colour. Its constitution is probably as follows:



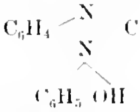
From the properties of the above tetramidodiphenyl it is evident that the four amido groups are arranged in two pairs, in each of which the groups are in ortho-position to each other. It follows that in Strakosch's dinitrobenzidine the NO_2 and NH_2 groups are similarly placed. The authors succeeded in removing the two benzidine NH_2 groups by diazotising, and subsequent removal of the diazo-groups by boiling alcohol, obtaining thus a new body, the symmetrical *metadinitrodiphenyl* $C_{12}H_8(NO_2)_2$. This is a yellow-orange substance forming fine dichroic needles from alcohol or acetic acid; it is soluble in benzene or cumene. It melts at 197—198°. It is reduced by tin and HCl to the symmetrical *metadiamidodiphenyl* $C_{12}H_8(NH_2)_2$. The hydrochloride of this base is readily soluble. The sulphate $C_{12}H_{12}N_2.H_2SO_4$ is slightly soluble in cold water, forming long needles from hot water; the platinum double salt $C_{12}H_{12}N_2(HCl)_2PtCl_4$ forms straw-yellow grains. Alkalis precipitate the free base from solutions of its salts as an oil which solidifies after a few days' rest. An isomer of Congo-red is obtained by combining the diazo compound with sodium naphthionate; it forms small yellow-orange plates. This substance dyes cotton in a soap-bath a fast orange without a mordant, but the affinity for the cellulose is much less intense than in the case of the benzidine azo-compounds; the cause of this affinity is therefore apparently connected not only with the diphenyl nucleus, but also with the position which the two azo groups bear to each other.—T. L. B.

β-Naphthoicaldehyde. E. Bamberger and O. Boekmann. Ber. 20, 1115—1119.

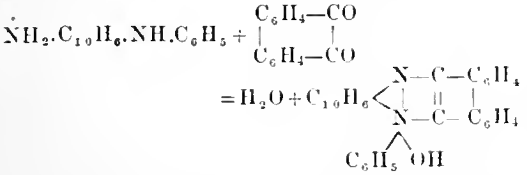
IN preparing this aldehyde, the authors obtained a series of new derivatives of naphthalene. For the production of *β-naphthoicthiamide* $C_{10}H_7.CSNH_2$, β-naphthylnitrile $C_{10}H_7.CN$, obtained from β-diazonaphthalene chloride by means of potassium cuprosocyanide, was digested with ammonium sulphide in a closed vessel at 35—40° for several days. It forms golden-yellow silky needles melting at 149°, and readily soluble in alcohol, ether and benzene. *β-naphthylmethylamine* $C_{10}H_7CH_2.NH_2$ is obtained by reducing an alcoholic solution of the thiamide with zinc dust and alcoholic solution of hydrochloric acid. It crystallises in colourless lustrous prisms melting at 59—60°, and absorbs carbonic anhydride freely on exposure to the air. It is sparingly soluble in cold water, more readily soluble in hot water and easily soluble in alcohol and ether. It is a powerful base. The hydrochloride crystallises in flat, satin like prisms melting at 260—270°. The picrate forms gold-coloured lustrous needles soluble in hot water, and the platinochloride crystallises from hot water in fine dendritic needles. *β-naphthylmethylalcohol* $C_{10}H_7.CH_2.OH$ is obtained by treating naphthylmethylamine hydrochloride with sodium nitrite. It crystallises in small lustrous plates, melting at 80—80·5°, and is readily soluble in alcohol and ether. On oxidation, it yields *β-naphthoicaldehyde* $C_{10}H_7CHO$, which forms small silver-white plates melting at 60·5—61°. This compound reduces an ammoniacal solution of silver and forms a leuco-base with dimethylaniline and zinc chloride, which yields a dye resembling benzaldehyde green in properties.—D. B.

On Azonium Bases. Otto N. Witt. Ber. **20**, 1183—1186.

THE formula recently proposed by the author for safranine is based upon the hypothetical base, which he terms *hydroxyphenylphenazonium*—



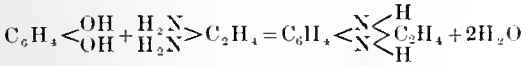
(This Journal, 1887, 285). All attempts to obtain this substance by removal of the amido-groups of phenosafranine, however, failed. The ease with which most orthodiketones react with orthodiamines, rendered it probable that phenyl-derivatives of the latter bases would behave in a similar way, in which case the desired azonium bases would be obtained. Experiment has proved the correctness of this idea, phenylorthonaphthylenediamine reacting with phenanthrenequinone as follows :—



The phenylnaphthylenediamine was obtained by reducing 10 parts of the perfectly pure azo-compound of sulphanilic acid and β-naphthylphenylamine, dissolved in 10 parts of glacial acetic acid and 100 parts of alcohol, with 12 parts of stannous chloride dissolved in 20 parts of acetic acid, and gradual addition of HCl till the solution is colourless. Its hydrochloride forms white needles insoluble in water, soluble in alcohol. The free base crystallises in glass-clear, flat prisms, melting at 136—137°. When equal quantities of this base and phenanthrenequinone dissolved in acetic acid, are mixed together, intermediate yellow fluorescent bodies are at first formed, an addition of a mineral acid causing the formation of the azonium base. The solution is diluted with alcohol and a good excess of nitric acid (sp. gr. 1·3) added, when the nitrate of the new base $C_{30}H_{19}N_3O_3$ slowly crystallises out in the form of long needles or thick prisms, with strong red and green dichroism. This salt is scarcely soluble in water, more so in alcohol, dyeing wool and silk a salmon red and behaving like a true dye. The other salts are much more soluble than the nitrate, and dissolve with a splendid blue colouration in strong sulphuric acid. The basic qualities are more strongly marked than in the case of the azines, the above salts only being basified by boiling with an excess of alkali.—T. L. B.

Action of Ethylenediamine on Catechol. V. Merz and C. Ris. Ber. **20**, 1190—1197.

WHEN ethylenediamine is allowed to act on catechol at 200—210°, the following reaction takes place :—



$$C_6H_4<\begin{matrix}OH\\OH\end{matrix}+\begin{matrix}H_2N\\H_2N\end{matrix}>C_2H_4=C_6H_4<\begin{matrix}N\\N\end{matrix}\begin{matrix}H\\C_2H_4\\H\end{matrix}+2H_2O$$

Ethylenеorthophenylenediamine crystallises from hot water or ether in small colourless lustrous plates, melting at 96·5—97° and boiling at 288·5—289·5°. It is sparingly soluble in cold, more readily soluble in hot water, and forms crystallisable salts with acids. Dilute aqueous solutions of the base give a blue coloration with ferric chloride and oxidising agents. It is converted into quinoxaline on treatment with an alkaline solution of potassium ferricyanide.—D. B.

A New Method for the Production of Picrocarmine. L. Gedölst. Le Monit du Practic. 1887, 91.

A PICROCARMINE of good colour, which filters well and may be boiled without decomposition, is made by substituting caustic soda for ammonia in its preparation. 95cc. of distilled water are added to 5cc. of a 1 per cent. NaOH solution, and in this mixture is dissolved 0·45grm. of the best carmine in the state of fine powder; the solution is stirred with a glass rod and boiled for 10 to 15 minutes, cooled, filtered and made up to 100cc. with water. It is next diluted in a 300cc. graduated glass cylinder with 100cc. of water, and is ready for the addition of a 1 per cent. acid solution, of which 20 to 25cc. should suffice. 15cc. of the picric solution is added first, producing a cloudiness which disappears on stirring; a further 5cc. still produces a transient turbidity, but with a final addition of 5 or at most 7cc. the precipitate becomes permanent and indicates the end of the reaction. After an hour's subsidence, the solution is passed twice or thrice through the same filter until clear, and concentrated by evaporation with, if necessary, a final filtration. The sodium picrocarminate is said to possess distinct advantages over the ammonium compound, and is recommended for microscopical work.—W. G. M.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

Method of Preparing Fibres capable of being spun from Wood. Alex. Mitscherlich, Freiburg, Germany. Eng. Pat. 10,545, Aug. 17, 1886.

BOARDS, as free from knots as possible, of any desired width, and about $\frac{3}{8}$ of an inch thick, are cut in a direction parallel with the fibre, preferably from pine or fir-wood or from the softer part of larch, and are boiled in a solution of sulphurous acid or a bisulphite whereby the disintegration of the wood is effected. No chopping is required, and before boiling the wood is steamed at 212° F. for a long time. After boiling, the mass is partly dried on a wooden frame and then passed through rollers having "deep ribs" in the direction of their length, the projections on one roller fitting in the corrugations of the other, whereby the fibres will be separated from each other and may be combed in an apparatus similar to that for combing flax, etc.—H. A. R.

VI.—DYEING, CALICO PRINTING, PAPER STAINING AND BLEACHING.

On Turkey-red Oils. R. Benedikt and F. Ulzer. Monatsh. Chem. **8**, 208.

THE product obtained by the action of concentrated sulphuric acid on triolein consists of two portions, one of which is soluble, whereas the other is insoluble in water. The latter is chiefly oxystearic acid and its anhydride, sometimes accompanied by oleic acid and unchanged triolein, while the soluble portion splits up under suitable conditions in oxystearic and sulphuric acids. The opinions on the nature of this soluble portion are divided. Liechti and Suida believe it to be a mixture of oxystearic acid and oxyoleic acid-glycerol sulphonic ether, which opinion is not shared by Müller-Jacobs and the authors. Müller-Jacobs and Tsabenejew take the soluble oil to be sulphonic acids, either sulpho-oleic or sulpho-oxystearic acid. The authors produced the sulphonic acid of a higher homologue by heating oleic acid with sulphur at 200—220° C. and oxidising the sulpho-oleic acid, $C_{18}H_{32}SO_2$, thus obtained with potassium permanganate. The object of this proceeding was to see whether compounds similar to the soluble Turkey-red oils, but belonging to a higher series, had similar properties. This is, indeed, the case. They are attacked by boiling concentrated caustic solutions, but differ from the acids derived from the Turkey-red oils by not being decomposed by hydrochloric acid. This behaviour seems to point to the fact that the acid from Turkey-red oil is no real sulphonic acid, but rather a sulphonic acid ether. The authors compared the Turkey-red oils from olive oil, which chiefly consists of triolein, cotton-seed oil and castor oil, and explain the difference in the behaviour of the olive and castor oil by the different constitution of oleic and ricinoleic acid. The latter, being an oxyacid, combines with sulphuric acid to an ether sulphonic acid, $C_{18}H_{33}O_2.O.SO_3H$, which, on decomposition, must yield ricinoleic acid and sulphuric acid, whereas the oleic acid combines with sulphuric acid to oxystearinsulphonic acid. The Turkey red oil from castor oil, therefore contains the acid sulphonic acid ether of an unsaturated acid, while the Turkey-red oil from olive oil contains the corresponding derivative of a saturated acid. The Turkey-red oil from castor oil therefore possesses a high oxidising power, which is not the case with the derivative of olive oil. The former is consequently the far better mordant for Turkey-red dyeing.—S. H.

Process for the Production of Alumina compounds applicable for Bleaching. R. Weiss, Oranienburg, Russia. Eng. Pat. 6573, May 15, 1886. 6d.

HYPOCHLORITE of alumina has long since been employed in bleaching, under the name of "Wilson's bleaching liquid," and has been preferred on the grounds that "it accelerates the bleaching process and deteriorates the fibres of the tissue much less than the chloride of lime." Up to the present, the usual method of manufacture has been by double decomposition of alumina sulphate and chloride of lime. "Experiments have proved that similar, but still more energetic bleaching compounds of alumina, are produced by the direct action of chlorine on aluminates, and especially on aluminates of sodium or calcium and of magnesium, whereby the use of chloride of lime is entirely obviated. These bleaching alumina compounds may be prepared either in the form of a solution, or in a solid form." Chlorine is passed through a solution of the aluminate or over the solid substance, till no more is absorbed. The inventor claims that the alumina compounds prepared in the manner he describes, act as very rapid bleachers "in consequence of the delivery of ozonised oxygen." "The use of acid baths is also dispensed with ; also these alumina compounds deteriorate the fibres much less than chloride of lime."—H. A. R.

Improvements in Dyeing Wool or other Animal Fibres, in either the raw or manufactured state. F. A. Gatty, Accrington. Eng. Pat. 9286, July 17, 1886. 6d.

IN carrying out the process of mordanting according to this method, the patentee instead of boiling the wool, alkaline chromate and acid together, as is usual, steeps the goods in the bichromate or chromate (of potash or soda) and the acid, preferably sulphuric, at the ordinary temperature of the air, and then after working for some time in this bath, washes and subjects to the action of boiling water or steam. Chromium oxide is thus fixed on the fibre, which is then ready for the usual dyeing operations. Before mordanting, the wool is well prepared and freed from all oily and similar impurity.—H. A. R.

Improvements in Dyeing Textile Fibres. T. Holliday, Huddersfield. Eng. Pat. 10,542, Aug. 17, 1886. 6d.

THE inventor dyes wool and other textile fibres various shades of colour by alternately treating the fibre with "chrome iron," copper or lead salts, and the nitroso-compounds of α and β-naphthol. "The quantities of wool or other fibre and the nature of the metallic salt, acid and nitroso-compound are varied according to the result required and the shades of colour varied by using logwood or alizarin along with or alternately with the nitroso-compounds. The fibres can be dyed either in a raw, spun, woven, felted or otherwise partly manufactured state."—H. A. R.

A New or Improved Method of Dyeing and Finishing Textile Fabrics without Immersion. W. E. Heys, Manchester. From H. Danzer, A. Simian and De Marcien, Paris, France. Eng. Pat. 11,161, Sept. 2, 1886. 8d.

THE solution of the dye is applied to the surface of the fabric in the form of a fine spray and the colour fixed by a jet or jets of steam playing upon the opposite side of the piece ; the finishing, dressing, etc., being also carried out in the same apparatus.—H. A. R.

Improvements in Dyeing. H. J. Haddan, London. From A. Henry, Bar-le-Duc. Eng. Pat. 11,730, Sept. 15, 1886.

THE claim is for the dyeing of cotton and other textiles a fast black by passing the goods rapidly and in small quantities through a bath of two solutions as follows :—The first solution consists of chlorate of potash, sulphate of copper, "chlorhydrate of ammonia," nitrate of iron and water ; the second solution consists of aniline, toluidine, etc., hydrochloric and tartaric acids ; the solutions are mixed just before use. The goods are then dried in a current of air for a short time at 35° C., and for about 12 hours at 30° C. without exposure to light. Afterwards the goods are passed through a bath of potassium bichromate, sulphuric acid and water, stretched and frequently turned in a dark place for about two hours, finally washed and dried.—H. A. R.

Improvements in the Manufacture of Oil for Turkey-red Dyeing, Calico Printing, and such like purposes. J. Kirkpatrick, Glasgow. Eng. Pat. 12,216, Sept. 25, 1886. 4d.

TEN gallons of olive oil are treated with 15 gals. of sulphuric acid at 168° B., washed with hot water and neutralised with 3 gals. of caustic soda at 68° B. and 1 gal. of ammonium hydrate 0·9 sp. gr.—W. L. C.

An Improved Process and Apparatus for Dyeing Unspun Textile Fibres. G. Jagenburg, Rydboholm, Sweden. Eng. Pat. 443, Jan. 11, 1887. 8d.

THE dye in the form of a concentrated solution is injected into the water contained in the vat and in which the goods are continually agitated. It is claimed that by this means the dyeing is even and without prejudice to the strength of the fibre, also that cotton dyed in this way remains soft and as fit for spinning as ordinary raw cotton, whereby it will be possible for spinners to spin dyed yarn up to the finest counts according to the quality of the cotton employed.—H. A. R.

An Improved Process of Preparing Indigo Solutions for Dyeing Purposes. F. E. Schmückert, Pritzwalk, Prussia. Eng. Pat. 7333, May 19, 1887. 4d.

THE inventor produces indigo solutions for dyeing purposes, especially for wool dyeing, by dissolving the indigo in water by means of Peruvian guano and the like ; also by adding bodies which absorb oxygen, such as zinc powder (at 65° to 75° C.), proposes to regulate automatically the process so that any supervision may become superfluous. It is claimed that such additions will obviate the defective treatment and consequent loss of indigo which frequently occurs in the preparation of the bath.—H. A. R.

VII.—ACIDS, ALKALIS AND SALTS.

Ammonio-zinc Chlorides. H. Thoms. Ber. **20**, 743—744.

IN addition to the compound of the formula $ZnCl_2.NH_3$, described by Berzelius, a compound of the formula $ZnCl_2.5NH_3 + H_2O$ has been recently observed. The author finds that if ammonia be passed into a hot concentrated solution of zinc chloride until the precipitate first formed is redissolved, nacreous scales separate on cooling, which have the composition $ZnCl_2.4NH_3 + H_2O$. On concentrating the mother-liquor, colourless rhombic crystals of the formula $ZnCl_2.2NH_3$ are obtained, which do not change on exposure to air, and are insoluble in water. When, however, boiled with water, decomposition takes place with evolution of ammonia and formation of zinc oxychloride. This compound is easily soluble in solutions of ammonium chloride or ammonia.

Well-formed crystals of the same compound have also been found in Leclanché cells (this Journal, 1887, 515), the following equations illustrating the formation:—

$$\begin{cases} ZnO + 2NH_4Cl = ZnCl_2 + 2NH_3 + H_2O \\ ZnCl_2 + 2NH_3 = ZnCl_2.2NH_3 \end{cases}$$

The author considers the constitution of this compound to be expressed by the formula $NH_3Cl\ Zn.NH_3Cl$.
—D. B.

The Borate Industry in Chili. Dr. L. Darapsky. Chem. Zeit. **11**, 605—607.

In a lengthy paper the author gives an account of this industry, and discusses the probabilities of its future development. Boric acid occurs on the west coast of South America, principally in the form of boronatrocalcite and is found throughout the province of Atacama and the newly-acquired portions of Chili. Ascotan—which is now on the borders of the republic, but formerly belonged to Bolivia—and Maricunga, which is to the north of Copeapó, are the places which have proved most successful commercially. The crude material occurs in both places in lagoons or troughs; these, instead of being entirely filled with common salt—as is usually the case in the desert—contain zones or layers of boronatrocalcite imbedded in it. The lagoons of Maricunga lie about 64km. from the nearest railway station, and are estimated to cover 3,000,000 sq. metres. The boronatrocalcite occurs in beds alternating with layers of salt and salty earth. The author gives a large number of analyses of the raw material, from which it would appear that the average amount of boric acid contained in it is about 25 per cent., but the percentage varies very much in different samples, and can be considerably increased by proper treatment; in one case quoted it was raised to 60·52 per cent. by washing and calcination (Kröhnke).

The raw material contains, in the form of gypsum and glauberite, a large amount of calcium sulphate, which apparently cannot be removed either by washing or mechanical treatment. Instead of investigating some method of working up the crude material into a better state for the market, the promoters of the industry appear to have turned their attention to the manufacture of crystallised borax. This was a fundamental mistake, for about half the weight of borax consists of water, and in the purest state it only contains 36·64 per cent. of boric acid; transport is therefore as costly as that of the raw material, the percentage of which can be raised to 30 simply by careful selection, and to 50 or 60 by dehydration. As there are no large chemical works in the country, the soda and acids required in making the borax had to be imported or specially made; and experience has shown that the conversion of boronatrocalcite into crystallised borax offers difficulties even when the requisite materials are easily obtained. The works at the Copeapó harbour, belonging to the Maricunga Co., were erected without sufficient knowledge and foresight, and never yielded satisfactory results. After a while the boronatrocalcite (roughly purified) was shipped direct to England and Germany, and finally all operations were suspended.—D. E. J.

The Borate Industry in Chili. L. Darapsky, Santiago, Chili. Chem. Zeit. **11**, 675.

The following analysis may be taken as representing the general average percentage composition of the mineral:—$H_2O = 29·0$; Al_2O_3 and $Fe_2O_3 = 0·7$; $Cl = 12·6$; $SO_4H_2 = 0·7$; $MgO = 0·5$; $CaO = 12·5$; $Na_2O = 14·8$; $B_2O_3 = 26·4$; insoluble matter $= 5·7$. The mineral is purified to some extent before it is shipped for export. This purification consists of a preliminary washing and drying operation, after which it may be considered to test as follows:—$H_2O = 11·76$; Al_2O_3 and $Fe_2O_3 = 3·08$; $Cl = 0·70$; $SO_4H_2 = 0·49$; $CaO = 12·48$; $Na_2O = 9·12$; $B_2O_3 = 55·20$; insoluble matter $= 7·31$ per cent. If the amount of the foreign impurities is not large, the percentage of boracic acid in the crude mineral may be estimated in a very simple manner. The sample is dissolved in hydrochloric acid and filtered, the sulphuric acid being estimated in one portion and the lime in another portion of the filtrate. The amount of lime which is equivalent to the sulphuric acid is subtracted from the total amount of lime, and the rest, multiplied by 3·1, gives the percentage of boracic acid.
—S. H.

On a New Class of Ferro- and Ferricyanides. J. A. Müller. Compt. Rend. **104**, 992—995.

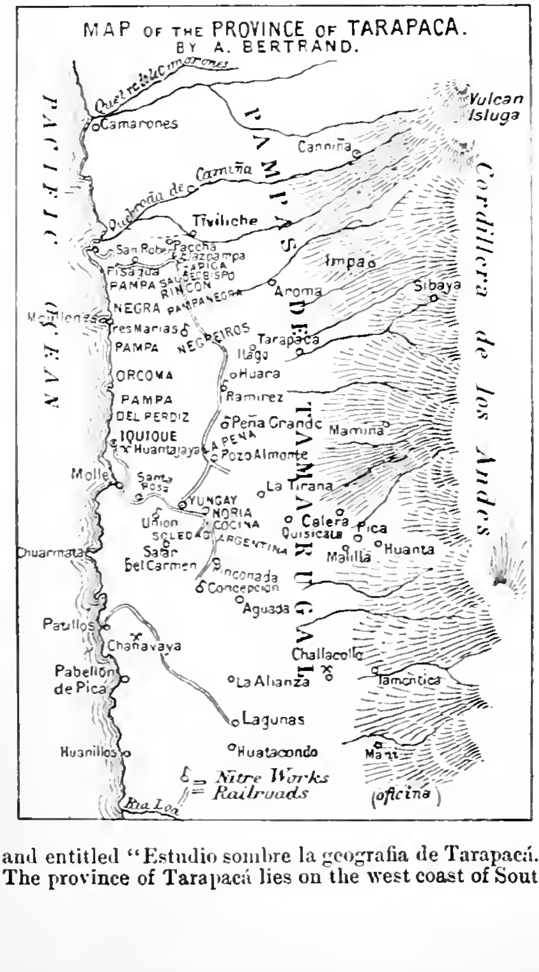
In the chemical works at Croix, where Ortlieb and Müller's process for obtaining cyanides is carried on, Ortlieb obtained a solution giving a violet precipitate, by fractional precipitation of the mother-liquor of the ferrocyanide with ferric chloride. By treatment of this precipitate with potassium carbonate and a subsequent process of purification, the potassium salt of the new substance was obtained in thin scales or plates very soluble in water. The solution is coloured violet by ferric chloride, and a precipitate settles out after one or two days.

The analysis of the new ferrocyanide corresponds to the formula $K_3FeC_6N_5O + 3\frac{1}{2}H_2O$. The water volatilises at 110°. Heated in a closed vessel to 300—400°, the substance loses 9·05% of its weight and yields 8·33% of CO. The formula $K_3FeCO(CN)_5$ requires 8·47%. In this decomposition ordinary ferrocyanide and cyanide of iron are formed amongst other compounds. The formula $K_3FeCO(CN)_5$ becomes explainable by the assumption of a trivalent radicle, carbonylferrocyanogen $[FeCO(CN)_5]'''$.

To the above is appended a note by C. Friedel, who finds in the existence of the substance $K_3FeCO(CN)_5$ a support to his proposed formula for the ferrocyanides.
—G. H. B.

The Nitre Deposit in Tarapacá. L. Darapsky, Santiago, Chili. Chem. Zeit. **11**, 752.

The report is an abstract of a book lately published by Mr. W. E. Billinghurst, himself a nitre manufacturer, and entitled "Estudio sombre la geografia de Tarapacá." The province of Tarapacá lies on the west coast of South



MAP OF THE PROVINCE OF TARAPACA.
BY A. BERTRAND.

America, between 68° 15' and 70° 18' long. and 19° 12' and 21° 28' 30" lat. The nitre deposits do not only occur in the province of Tarapacá, but also further south, especially near Antofagasta and Taltal. From east to west the province may be divided in five zones. The first reaches from the sea coast for a width of 74 miles, and yields guano. It also contains many silver mines, among which is the famous mine of Huantajaya. The second zone is the nitre zone. It occurs at an altitude of 3600ft., and goes down to the Pampa de Tamarugal. The third zone is the pampa, devoid of water and vegetation. The fourth, between the Pampa de Tamarugal and the Cordillera de los Andes, contains silver and copper mines, whereas the fifth, the Cordillera, is scarcely explored yet. The natives are said to collect sulphur here. The author then proceeds to the valuation of the total quantity of nitre which may be expected from the second zone, and states his conclusions in the following table :—

Group.	Number of Estacas.	Exhausted Estacas.	Untouched Estacas.	Average Yield of Nitre per Estaca in Spanish cwts.	Total Quantity of Nitre in Spanish cwts.
North	5,611·50	1,208·62	1,402·87	145,958·71	204,750,878·38
Pampa de Huara	1,000·00	—	1,000·00		145,958,710·00
Midland	5,150·50	3,433·66	1,716·83		250,611,105·07
South	9,450·00	—	9,450·00		1,379,309,809·50
	21,212·00	7,642·28	13,569·70		1,980,630,502·95

* 1 Estaca = 40,000 Square Varas = 27,949·55 Square Metres.

The State receives an export duty of 27968d. per Spanish cwt., which is equivalent to the sum £230,809,474 for the total 1980 millions spanish cwts.—S. H.

Two New Hydrates of Caustic Potash. C. Göttig. Ber. **20**, 1094—1096.

ONE hydrate of potash $KHO+2H_2O$ is already known. The author has prepared two new hydrates :—

1. From a concentrated solution of caustic potash in strong alcohol, prismatic crystals of the formula $2KOH+9H_2O$ separate out. These crystals lose 3 molecules of water over sulphuric acid.

2. If a moderately concentrated solution of potash in strong alcohol be evaporated down until the temperature of the boiling liquid rises to 110°, and then allowed to cool, the new hydrate crystallises out in a mass of fine needles of the formula $2KHO+5H_2O$.—J. B. C.

On Antimony Pentachloride. R. Anschütz and N. P. Evans. Annalen, 1887, 285.

IF a solution of antimony pentachloride in chloroform be treated with the equivalent quantity of water, crystals, of antimony pentachloride monohydrate $SbCl_5.H_2O$ are formed, which melt between 87° and 92° C., and are very deliquescent. A larger quantity of water converts the monohydrate into the tetrahydrate, which is insoluble in chloroform. Daubrawa's statement that antimony pentachloride is decomposed by one molecule of water into the oxychloride and hydrochloric acid could not be confirmed. The authors attempted to produce the oxychloride by the action of the pentachloride on anhydrous oxalic acid, but they obtained a new compound, $C_2O_4Sb_2Cl_8$, which is decomposed by warm water. On the basis of these results the different behaviour of phosphorus and antimony pentachloride to carbon compounds, which contain both hydrogen and oxygen, can be explained. Whereas antimony pentachloride combines with water, phosphorus pentachloride decomposes it. The former, therefore, does not exchange chlorine for oxygen, whereas the latter displaces oxygen in hydroxyl and ketone groups by chlorine, being itself converted into phosphorus oxychloride. On the other hand, the antimony pentachloride acts similarly to phosphorus pentachloride on carbon compounds, which contain no oxygen. The same will be the case if the compound contain no hydrogen atoms which are not combined to carbon. The oxalic acid is a case in point, and the production of a compound like $C_2O_4Sb_2Cl_8$ or $SbCl_4.COO—COO.SbCl_4$ makes the existence of $PCl_4.COO—COO—PCl_4$ probable. The investigations of Anschütz and some of his pupils show that phenols and oxyacids, which contain an oxygen atom which is very difficult to displace, are likely to yield directly or indirectly compounds of the general formula $R.O.PCl_4$.—S. H.

Process for the Production of Alumina Compounds applicable for Bleaching. R. Weiss, Oranienburg, Russia. Eng. Pat. 6573, May 15, 1886. 6d.

SEE page 544.

Improvements in Means or Apparatus employed in the Manufacture of Sulphites. A. W. Gillman and S. Spencer, London. Eng. Pat. 10,000, August 4, 1886. 8d.

THE following arrangement of apparatus is employed by the inventors in the manufacture of sulphites:—Sulphurous acid is generated in a sulphur kiln, and the gas is cooled by suitable means before it passes into the limestone tower. The latter is constructed of headless casks placed one above the other, the ends of the casks are bevelled to fit each other, and are connected by leaden bands. The limestone is supported on a wooden frame in the lower part of each tower, so as to leave a free space below for drainage and the entry of the gas. The gas in rising through the limestone is to a great extent absorbed by the descending water, which is admitted at the top of the tower, and the saturated water dissolves out lime from the limestone, forming a solution of calcium bisulphite which runs from the bottom of the limestone tower into suitable store tanks. For the manufacture of calcium monosulphite the sulphurous acid gas is conveyed to the bottom of a chamber provided with trays, on which sifted slaked lime is spread, the trays being so arranged as to make the gas pass to and fro over the lime. The top of the chamber is removable to enable the trays to be charged and emptied. Sulphite of soda or potash is made in similar chambers, the trays being filled with a solution of sodium or potassium carbonate, which is admitted at the top of the chamber through a bent pipe and flows over the trays, descending from one tray to another until it arrives at the bottom, meeting in its course the current of gas which traverses the chamber in the opposite direction.—S. H.

Improvements in Separating the Ammonium Chloride from Liquors obtained in the Manufacture of Soda by the Ammonia-Soda Process. G. Jarmay, Winnington. Eng. Pat. 10,419, August 14, 1886. 6d.

THESE improvements relate to the separation of ammonium chloride from the spent liquors of the ammonia-soda process. It is proposed to lower the temperature of these liquors by artificial means, until a sufficient quantity of ammonium chloride has crystallised out. After the crystals are separated, sodium chloride is added to the mother-liquor and the liquor afterwards again cooled, when an additional crop of ammonium chloride crystals is secured. The addition of salt and subsequent cooling is several times repeated. The mother liquor is ultimately used again in the place of brine for the initial stage of the ammonia-soda process, thereby saving the expense of distillation and effecting a great economy of sodium chloride.—S. H.

Improvements in the Manufacture of Alkali. J. Barrow, Manchester. Eng. Pat. 10,491, August 16, 1886. 6d.

Sodium sulphate is decomposed by barium sulphide, or a mixture of barium sulphide and oxide, whereby a solution of sodium sulphide and oxide and a precipitate of barium sulphate is obtained. The latter is separated by filtration, and the filtrate is treated with carbonic acid, thus converting the solution into sodium carbonate and bicarbonate, both of which may be obtained at will according to the amount of carbonic acid added. At the same time sulphuretted hydrogen is given off, which is worked up for sulphuric acid to be used in the conversion of sodium chloride into sulphate. The precipitate of barium sulphate is reduced to sulphide or a mixture of sulphide and oxide by means of carbonaceous matter.
—S. H.

Improvements in Machinery for Charging Liquids with Carbonic Acid Gas. F. Foster, Hoxton. Eng. Pat. 10,722, August 21, 1886. 8d.

This invention relates to a modification of an apparatus described in a previous specification (Eng. Pat. 2426, 1882). The machine there described was fitted with an arrangement for generating, storing and delivering carbonic acid gas in a compressed form to the condenser containing the liquid to be aërated. The present invention dispenses with all those parts, as it is now intended to use portable vessels containing compressed carbonic acid gas.—S. H.

Improvements in the Manufacture, Purification, or Separation of Sodium Bicarbonate. J. J. Watts and W. A. Richards, Sandbach. Eng. Pat. 10,955, August 27, 1886. 4d.

The sodium bicarbonate, as obtained in the ammonia-soda process, contains ammonium compounds and tarry matters. Mond and Jarmay (this Journal, 1885, 282) purify the crude bicarbonate by dissolving it in water and recrystallising it from the solution by refrigeration. The yield of crystals being small, the present inventors increase the yield by adding to the warm saturated solution of sodium bicarbonate a quantity of common salt, which, on dissolving, separates sodium bicarbonate. The yield of the latter is in proportion with the quantity of sodium chloride added and dissolved. The mother liquor may be used for dissolving fresh quantities of crude bicarbonate, or for the initial stage of the ammonia-soda process in lieu of brine.
—S. H.

VIII.—GLASS, POTTERY AND EARTHENWARE.

A New and Improved Process for Producing Ornaments and Lettering on Glass, or other Round or Flat Substances, for Decorating and Advertising Purposes. F. Winterhoff, London. Eng. Pat. 5978, May 3, 1886. 6d.

Glass and other surfaces are sometimes coated with a solution of a substance such as "asphalte," which is rendered insoluble by the action of light. A photographic negative is placed over the coated surface and exposed to light, part of the coating is thus rendered insoluble, the remainder is dissolved away, and the portions of the glass, etc., so left exposed are etched with hydrofluoric or other acid. According to this invention, the surface to be treated is coated with a solution of asphalte in spirit of turpentine. The matter to be etched is drawn or engraved on a lithographic stone or steel plate, from which as many impressions as are required are printed with printing ink on to lithographic transfer paper. The pattern or design is then transferred from the paper to the coating on the glass or other article to be etched. The transferred matter is now dusted or covered with bronze powder, gold or other metal leaf, or any fine powder which obstructs the passage of light. The powder adheres to the printed matter only, and forms above it an opaque surface. After exposure to light the surface is treated with paraffin oil, the asphalte coating being removed from those parts which have been protected from the action of the light. The surface is now ready for "aciding" in the usual manner.
—E. G. C.

Improvements in or relating to the Manufacture of Glass. E. Picard, Brussels, Belgium. Eng. Pat. 7338, June 1, 1886. 11d.

This invention relates to the production of a layer or sheet of glass of uniform thickness and of indefinite length, which, without break of continuity, can be cast, rolled, tempered or annealed, straightened or flattened, polished and cut into suitable pieces; also to a method of manufacturing glass consisting in the formation of a continuous layer or sheet, by means of a rolling apparatus combined with a continuously fed reservoir or tank and with an annealing or tempering gallery, provided with a movable table, in which the sheet is tempered or annealed without further heating.
—E. G. C.

Improvements in the Production of Fireproof Materials and Articles of Enamel. A. Feldman, Linden, Prussia. Eng. Pat. 8064, June 17, 1886. 6d.

Fireproof and enamelled articles are produced from a mixture of one or more of the fluorides of sodium, calcium, magnesium, strontium, barium and aluminium with one or more of the following basic oxides: lime, magnesia, baryta, strontia, alumina, and oxide of zinc. The substances to be employed are powdered and mixed with water to form a dough, which is dried and burnt at such a temperature that its ingredients will sinter together.—E. G. C.

Improvements in the Manufacture of Porous Earthenware. H. J. Allison, London. From C. G. Gilman, Iowa, U.S.A. Eng. Pat. 15,579, Nov. 30, 1886. 6d.

Clay is mixed with vegetable matter, cut in short lengths, pressed, dried, burnt in a kiln and shaped with edged tools to the desired form.—E. G. C.

The Manufacture of Opaque Glass of a New Colour. E. Moore, South Shields. Eng. Pat. 4822, March 31, 1887. 4d.

A light brown or fawn colour is imparted to opaque glass, by adding to the ordinary batch used in making the glass any of the following substances:—Flowers of sulphur, calcined oats, or other calcined cereal, vine stalks, etc.—E. G. C.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

Improvements in the Processes and Manufacture of Cement in a Powdered State, and the Apparatus relating thereto. F. W. S. Stokes, London. Eng. Pat. 7888, June 12, 1886. 1s. 1d.

This is an improved process which consists in introducing finely powdered slurry or other cement material, while held in suspension in air or gas, into a chamber, subjecting it therein, while still held in suspension, to the action of heat, and then separating the particles of cement from the gases or products of combustion. Various improvements in apparatus, etc., are described in detail in the specification.—E. G. C.

X.—METALLURGY, Etc.

Which Form of Blast Furnace least hinders the regular descent of the Charge? F. W. Larmann. Stahl u. Eisen, 1887, 163.

THE author considers that the charge rests more lightly in a furnace without, than in one with boshes. A wide furnace with but slightly contracted area gives free space for the descent of the charge and is indeed practically without boshes; but a furnace in which the retarding action of the boshes on the downcoming materials makes itself felt even in the centre, is objectionable. A charcoal furnace built on the author's principle was run regularly on grey, mottled or white irons of extremely high quality, working steadily and without derangement for fifteen months. It was 9·651 metres high, 1·25 metres in diameter beneath, and 1·10 metres at the mouth; from below, to a height of 1·255 metres, it rose cylindrically, and was thence evenly reduced in diameter, making an inclination of 1° with the vertical. The furnace was of 10cbm. capacity, and produced on an average 6000kilos. per 24 hours, equivalent to 1 ton of metal per diem per 1·67cbm. capacity—thus comparing favourably with the larger coke furnaces in Germany and in the Cleveland district, of which the outputs are 1 ton per 3cbm. and per 10cbm. respectively. On blowing out the furnace it was found that the greatest diameter was at the tuyeres, from which the writer concludes that the shoulder of the boshes is quite unnecessary.—W. G. M.

Notes on the Recovery of Copper, Lead and Silver from Rio Tinto Burnt Ore. Chem. Zeit. **11**, 753 and 785.

THE burnt ore coming from the pyrites kilns tests as follows:—

Fe_2O_3	77·00 — 78·00 %
FeS	3·75 — 4·00
CuO..........	2·75 — 2·90
S	3·00 — 3·70
CuS..........	1·50 — 1·75
Pb	0·30 — 0·50
Ag	0·0025— 0·0050

The result of a year's working (1886) at a well-managed works was as follows:—

Burnt Ore worked up.	Metallic Copper.	Sulphate of Lead.	Silver Precipitate.	Flue-dust.
10,000,000 Kilos.	158,000 Kilos.	71,000 Kilos.	3,109 Kilos.	30,000 Kilos.
		(28 % Pb)	(48 % Pb)	(20 % Cu)
		(1—1·5 % Ag)	(26 % Ag)	(5 % Pb)
		(0·0018 % Au)	(0·031 % Au)	

—S. H.

On the Influence of a Heated Blast on the Composition of the resulting Pig Iron. A. Ledebur. Stahl u. Eisen, 1887, 168.

THE author has experimented with two samples of foundry pig produced from precisely the same materials, but one with a heavy charge of fuel and with cold blast, the other with a blast heated to 350° C. The fractures were alike that of a good grey charcoal pig; the only noteworthy differences in composition being observed in the percentages of carbon and silicon, the carbon in the cold blast metal being 4·363, and in the hot blast iron 4·063—an increase in the former, due probably to the longer period of exposure to the carburising influences, owing to the greater proportion of fuel in the charge. The silicon was lower in the cold blast pig, the proportion being 0·635 : 1·168. Hence it is probable that the cold blast metal was slightly the stronger of the two. The question whether foreign earths existing in the charge are more largely reduced at the higher temperature of the hot blast furnace is negatived by the fact that aluminium, titanium, calcium and magnesium are rarely found in the pig and never in sufficient quantity to influence appreciably its mechanical properties. The correctness of the theory that the heating of the blast facilitates the reduction of deleterious bodies, is therefore reasonably open to doubt. W. G. M.

Chemical Notes for Foundrymen. Otto Gmelin. Oestern. Ztschr. f. Berg. u. Hüttenw. 1887, 155.

On the Introduction of the Blast and the Formation of Carbonic Oxide in the Cupola and matters connected therewith.—The lowest zone of the charge should, as far as practicable, be evenly penetrated by the blast, to ensure complete combustion and a uniformly high temperature. The blast pressure for large cupolas should not exceed 55cm. of water, and should be even less for those of which the shaft diameter is under 800mm.; a stronger blast produces a cold blown metal. Two tuyères will generally be sufficient, but the actual number is of little consequence, provided that the relation of the aggregate areas of the tuyères to that of the shaft be not less than 1 : 2·5; the arrangement of tuyères in two superposed bands has no advantages over the usual disposition. The diameter of the shaft should not exceed 900mm.; works requiring to run down more than 6000kilos. per hour would find two cupolas preferable to one of larger size. Finding that a cupola gives so much the more favourable results the lower the zone of high temperature is maintained, the author has constructed a water-cooled furnace with double sheet metal casing, and has found it to give most satisfactory results.

—W. G. M.

Improvements in the Process of obtaining Alloys of Aluminium with Copper and with other Metals. J. Clark, Birmingham. Eng. Pat. 10,594, August 18, 1886. 6d.

HYDRATED aluminium chloride, obtained by treating clay or other aluminous matter with *aqua regia* or commercial hydrochloric acid, is heated with a reducing agent; a mixture of 3½ parts of granulated zinc with 1 part of iron borings is preferred, but ammonia or its bicarbonate may be employed instead. The residue is then mixed with a suitable proportion of shot copper and with fluxes, and fused in crucibles to melt the alloy, and to volatilise the chlorides of the reducing metals.—W. G. M.

Improvements in the Production and Treatment of Steel. R. Hadfield, Sheffield. Eng. Pat. 566, Jan. 13, 1886. 6d. Amended Specification.

THE emendation consists in a slight variation of the amounts of silicon and manganese originally employed.

—W. G. M.

XI.—FATS, OILS AND SOAP MANUFACTURE.

Improvements in the Treatment of Fish and other Matters to Extract Oil or Fat therefrom and in Apparatus to be employed therein. J. S. Edwards, Eastbourne. Eng. Pat. 6736, May 19, 1886. 8d.

THE fish or other material is placed in a closed vessel, connected with a steam boiler by pipes which run both from its top and bottom. A constant circulation of hot water is thereby maintained, so that the fat is washed out. From the mixture thus obtained, the fat is separated by simple subsidence. In some cases, pumps may be used to draw or suck the hot water through, or any other liquid heavier than the fat, as *e.g.* petroleum, may be employed. Drawings are given.—W. L. C.

On the Non-acid Constituents of Bees-wax. F. R. Schwalb. Arch. Pharm. **13**, 979.

THE author has carefully re-investigated the matter with the following results:—(1) Besides higher fatty acids and alcohols, bees-wax contains hydrocarbons, two of which boiling at 60·5° and 68° were isolated. (2) The highest melting alcohol has the formula $C_{31}H_{64}O$ (not $C_{30}H_{62}O$, as stated by Brodie). (3) Besides myricyl alcohol, bees-wax contains ceryl alcohol ($C_{27}H_{56}O$), and a third alcohol ($C_{25}H_{52}O$).—F. W. T. K.

Improvements in Apparatus for Expressing Oil from Oleaginous Substances, and for similar purposes. H. H. Lake, London. From La Société Anonyme du Compresseur Jourdan, Paris, France. Eng. Pat. 10,833, August 24, 1886. 11d.

THE apparatus consists of a hydraulic press with two rams and two receptacles so arranged that while the compressed cakes are being prepared in or removed from one, fresh material for compression can be introduced into the other. The apparatus therefore performs double the work of an ordinary press. In some cases the receptacles are mounted on rollers and transported from the compressing ram to the emptying rams. Filter plates of peculiar and special construction are employed. Elaborate drawings are given.—W. L. C.

A Process for the Treatment of Wool Fat to Produce Unguent Material therefrom. H. W. Langbeck, London. Eng. Pat. 11,192, Sept. 12, 1886. 6d.

THE raw fat is treated with solvents, such as a mixture of alcohol and carbon disulphide, to remove the fatty acids, cholesterin, etc., and the remaining fat is treated with animal charcoal (preferably "Prussia waste"), and from this mixture the pure wool fat is dissolved out by benzine, naphtha, etc., the solvent being in its turn removed by the injection of steam.—W. L. C.

An Improved Washing Powder. J. E. Quayle, Liverpool. Eng. Pat. 11,560, Sept. 11, 1886. 4d.

CARBOLIC ACID hard soap and the ordinary dry soap of commerce are dried and ground together in equal weights.—W. L. C.

A New or Improved Process for Oxidising Oils and Fats and other Organic Substances. C. Schill and C. Seilacher, Stuttgart, Germany. Eng. Pat. 12,799, Oct. 6, 1886. 6d.

TRAIN OIL or other fat, heated to 120° C., is supplied to an injector apparatus, which is worked by heated air at 4 or 5 atmospheres' pressure. The "grease-mist" thus produced is condensed in suitable chambers. Ozonised air, or a mixture of air and ammonia, may be employed with advantage in some cases.—W. L. C.

A Process for Extracting Oil or other Lubricants from Greasy Waste or Cleaning Cloths, and for Making the Extracted Grease into Soap. S. Schofield. Eng. Pat. 5960, April 23, 1887. 4d.

THE cloths, etc., to be extracted are put into a washing machine with an alkaline solution. The soapy water thus produced is decomposed with acid, the resulting rough grease pressed and, if desired, re-saponified.
—W. L. C.

Method and Apparatus for Distilling Fatty Acids by Means of Superheated Steam. W. Sanzenbacher and S. Tanatar, Odessa, Russia. Eng. Pat. 6986, May 12, 1887. 8d.

IN the ordinary plant for distilling fats, the steam is superheated in a furnace separate from the still. In the arrangement here patented, the superheating coils are inside the still, and are so arranged that, until the steam reaches 200° C., it escapes into the air, after which it is turned into the fatty matters. The steam is, therefore, always very slightly cooler than the fatty matters, instead of being much hotter, as is often the case, much to the detriment of the distilled product. Another feature of the apparatus is that the latent heat of the fatty acid vapours is utilised to heat the fatty acids that are to be distilled, when the apparatus is worked continuously. Great economy in fuel, and great improvement in the products, are claimed for the arrangement.
—W. L. C.

XII.—PAINTS, VARNISHES AND RESINS.

On the Changes which Vulcanised Caoutchouc undergoes. Balland. Pharm. Chim. **15**, 417.

VERY elastic caoutchouc tubing becomes gradually covered with white spots, which penetrate into the interior, in consequence of which the caoutchouc loses some of its elasticity. Later, the tubes break on stretching, even if previously laid in warm water, and finally they crack if pressed between the fingers. This change the author puts down to a very slow formation of sulphuric acid by the action of moist air on the sulphur contained in the caoutchouc. By frequent washing with slightly alkaline water the action of the acid is prevented. Tubes which were washed five or six times a-year remained perfectly elastic.—A. R.

Obtaining certain Products or Substances from Essence of Birch Bark, and utilising the same in the Manufacture or Production of certain Compounds or Substances. W. L. Wise, London. From E. Mourlot, Paris, France. Eng. Pat. 7903, June 12, 1886. 6d.

THE inventor obtains from essence of birch bark, by rectification, an essential oil, which possesses among other properties that of being fatal to "insect life," and an electrically insulating tarry substance. These two products are so treated and combined with other substances as to produce an anti-oxidising material and an insulating substance capable of the same applications as ebonite. Among the other ingredients employed, in additon to the products from the essence of birch bark, are caoutchouc, sulphur, chalk, talc, litharge, antimony sulphide, kaolin, zinc white and red ochre.—E. G. C.

A New or Improved Manufacture and Process of Production of Material that can be used as or in the Making of Substitutes for Indiarubber, Varnish, Ivory, Whalebone and other Substances. F. Greening, Uxbridge. Eng. Pat. 8442, June 26, 1886. 6d.

FIBROUS SUBSTANCE of any suitable kind, such as paper, old rag, grass, cotton, etc., is saturated with a mixture of sulphuric acid and potassium nitrate, and maintained for about 20—24 hours at a temperature of from 75° to 90° F. The converted fibre is then freed from excess of the mixture by pressure or otherwise, washed with water and dried sufficiently to be submitted to a suitable bath for neutralising the excess of acid. "Such a bath may be of liquid carbonic acid, or carbonic acid gas may be used. The fibrous mass is to be thoroughly impregnated with the carbonic acid, and afterwards allowed to dry; when dry it will be ready to be treated with a suitable solvent or solvents." A suitable solvent is produced as follows:—To 100galls. of methylated alcohol are added from 25—30lb. of refined colophony, from 10—12lb. gum benzoin and from 80—100lb. of castor oil. The mixture is distilled until the temperature reaches 300—320° F., and the distillate is dried by quicklime or calcium chloride. The residue in the retort is suitable for waterproofing or for mixing with the prepared base before described.—E. G. C.

Improvements in the Manufacture of Indiarubber Waterproof Textile Fabrics. P. M. Matthew, jun., Edinburgh. Eng. Pat. 9337, July 19, 1886. 6d.

FOR several years waterproof textures have been made by coating various fabrics with a thin film of indiarubber, and coating the surface so obtained with a layer of farina or other substance capable of producing a lustrous or ornamental effect. This inventor covers the indiarubber surface with some light fabric of an open nature, such as lace or similar material, in such a manner that the greater part of the rubber surface remains exposed. The network or open fabric is attached under considerable pressure to the rubber surface while the latter is still tacky or adhesive. The farina or other ornamental material is then spread over the whole surface, and adheres to those portions of the indiarubber which are still exposed. The fabric may be vulcanised either before or after the application of the farina or ornamental powder.—E. G. C.

Improvements in Making White Paint. J. B. Hannay, Dumbarton, and E. J. Pape, Oxton. Eng. Pat. 9581, July 24, 1886. 4d.

Oxide of zinc is combined with a white pigment, consisting principally of sulphite or chlorosulphite of lead, the mixture being subsequently ground up with a suitable oil or medium to form the paint.—E. G. C.

The Manufacture of a Transparent Flexible Material Suitable for all Purposes where a Transparent, Flexible and Light Material is required, such as a Base for Photographic Pictures, Transparent Show Cards, Artistic Work, Similar and other Purposes. F. H. Froedman, Dublin. Eng. Pat. 10,659, August 20, 1886. 6d.

This invention consists in rendering gelatin or other colloid insoluble with chromium salts and converting these bodies into colourless transparent and pliable films by means of sulphurous acid or its compounds. Gelatin is softened in water, then dissolved in a certain quantity of water on the water-bath and bichromate of potash added. Alcohol, and if necessary a small proportion of glycerine, is also added. Clean glass plates which have been dusted with French chalk are coated with enamel collodion, and when set, immersed in water till the coated surface is free from greasiness. The plates are then coated with the hot gelatin solution and dried at 65—70° F. When dry they are exposed to light and then washed in water, after which they are immersed in a solution of sulphurous acid or its compounds, and when sufficiently acted on are thoroughly washed and then dried. The following is a mixture which may be used advantageously:—Best hard gelatin 3 parts, water 24 parts, 4 parts of a 6 per cent. solution of bichromate of potash, alcohol 4 parts, glycerin $\frac{1}{4}$ part. —B. H.

Improvements relating to means for rendering Textile Fabrics and other Substances Impermeable, or for Protecting them from Injury by Moisture. W. R. Lake, London. From C. Orlay, Milan, Italy. Eng. Pat. 10,828, August 24, 1886. 6d.

The inventor claims to be able to retain acetate of alumina in the fibre, "by means of a pitchy varnish, insoluble and not powdery, without however obstructing the pores of the fabric." This substance, according to the nature of the fabric and its colour, is applied in either a dry or a hot state, after they have been subjected to baths of acetate of alumina, soap and alum, and after they have been dried in a drying stove at about 30° C.

The soap bath is made up with either a solution of soap of 1, 2 or 3 per cent. or an emulsion of soap, paraffin and resin. The alum bath contains 4 per cent. of alum. For cloth, a gall-nut bath comes before the alumina process and then stoving with hot plates not exceeding 36—40° C. The next process consists in treating with the following substances:—Paraffin wax, wax and vaselin, the proportions of each varying according to the nature and thickness of the fabric. A metallic soap, such as of iron, copper, zinc or the like may be added according to the colour desired. Besides for paper, pasteboard, etc., this preparation also serves for treating leather, hides, ropes, etc., also for the manufacture of awnings.—H. A. R.

Manufacture of Material for Removal of Old Paint. M. Benedictus, Brussels, Belgium. Eng. Pat. 10,960, August 27, 1886. 6d.

This invention relates to the manufacture of a material which, when laid by a brush or spatula on old paint, has, in the course of an hour or less, such action on the paint that the whole can be readily sponged off with water without any scraping. The material in question consists of a mixture of water, flour or meal, alum, black soap, with caustic soda and caustic potash.—E. G. C.

Improvements in Apparatus for the Manufacture of Varnish. W. L. Wise, London. From R. Lehmann, Dresden, Germany. Eng. Pat. 6323, April 30, 1887. 6d.

This inventor claims—(1) an apparatus heated by superheated steam for melting resins, such as amber and copal, consisting mainly of a melting vessel provided with a rising body and cover, and surrounded by a steam jacket; and (2) the use in conjunction with this apparatus of a vessel, surrounded by a steam jacket, into which the waste steam from the melting apparatus is introduced, to heat the oil varnish before and during its mixture with the melted resin.—E. G. C.

Improvements in Compositions for the Manufacture of Articles by Moulding, Carving or Turning, or of Varnish and Lacquer, and for similar Purposes. H. H. Lake, London. From E. N. Todd, Newark, New Jersey, U.S.A. Eng. Pat. 6870, May 10, 1887. 4d.

The object of this invention is to effect the solution or conversion of soluble nitrocellulose by means of a "latent solvent" other than camphor, and also to enable solutions of pyroxylin dissolved in any of the known solvents and mixed with any of the known menstrua, to be used as lacquers or varnishes, which shall be free from iridescence or irregularities. These desiderata are attained by the use of balsam of tolu, which the inventor has found to be a "latent solvent" of pyroxylin, in place of camphor.—E. G. C.

Improvements in the Manufacture of Pigment or Paint. H. H. Lake, London. From J. P. Perkins, Pullman, U.S.A. Eng. Pat. 7524, May 25, 1887. 6d.

The inventor reduces silicate iron slag to a granular or pulverulent form, calcines it and mixes it with oil or some other suitable vehicle. Colouring matters may be added, with the view of producing other than the natural shades of the calcined material.—E. G. C.

Improvements in the Preparation of Fireproofing Fluids or Paints, to be applied to Textile and other Inflammable Materials. G. Harrison and O. Trimming, London. Eng. Pat. 7809, May 28, 1887. 4d.

The articles to be fireproofed are dipped in a solution prepared by adding to one gallon of water sixteen ounces each of ammonium sulphate, powdered borax, and potash alum, and one ounce of boracic acid. After immersion, the materials are wrung out, dried and ironed in the ordinary way. The paint is prepared by first mixing with the above preparation enough whitening to form a thin paste and then adding boiling size until the mixture is thinned to the gauge of ordinary paint. Any colour may be imparted to the paint in the usual way.—E. G. C.

XIII.—TANNING, LEATHER, GLUE AND SIZE.

Tannin from Oak Wood. C. Böttinger. Ber. **20**, 761—766.

The author has investigated the tannin of oak wood, which has of late occurred largely in commerce in the form of an extract. In order to separate the tannin he used the method previously described by him (this Journal, 1884, 526), which consists in converting it into the acetyl compound. *Acet-tannin* from oak wood is a greyish-white heavy powder, soluble in water and cold alcohol, but insoluble in boiling absolute alcohol; it slowly loses acetic acid on exposure to the air. On analysis it gives numbers corresponding to the formula $C_{15}H_7(C_2H_3O)_5O_9$. Fused with potash it is decomposed, yielding acetic acid, protocatechuic acid and an undetermined phenol. It is also decomposed, yielding the corresponding tannin by heating for two hours with water in a sealed tube at 135° with frequent shaking and subsequent treatment with water and absolute alcohol. The *tannin* from oak wood thus purified forms a light yellow hygroscopic powder readily soluble in water; the aqueous solution gives no precipitate with bromine, but a brown precipitate with excess of caustic soda, a yellowish-white precipitate with lead acetate and a flocculent precipitate with gelatine solution: with solutions of the alkaline earths it only gives a precipitate after addition of ammonia. When dried in a desiccator the substance gives numbers corresponding to the formula $C_{15}H_{12}O_9 + 2H_2O$, and on heating it loses 1 molecule of water at 100° and the second at 125° without alteration of properties. Tannin from oak wood is not soluble in a mixture of bromine and water, differing in this respect from the sumach-tannin and its acetyl compound. When heated at 130° with bromine water, it appears to yield the same substance as the bromine derivatives of oak-bark tannin, hemlock tannin and the tannin of Terra japonica.

The acet-tannin from oak wood when treated with bromine in chloroform solution yields a substance which appears to be a monobromo-derivative containing one acetyl group. This substance can be easily converted into a higher bromine derivative by adding excess of bromine to the chloroform solution and warming the precipitated oil at 40—50°; the product has the composition $C_{15}H_7Br_4(C_2H_3O)O_9$.

The author concludes from the foregoing experiments that oak-wood tannin is the methyl salt of digallic acid, and that it has quite a different constitution to tannin, as shown by its action towards bromine, alkalis and moulds (*Penicillium glauc.*, etc.). With the two latter it forms gallic acid.—G. H. M.

Improvements in Treating Hide or Skins. J. Townsend, Glasgow. Eng. Pat. 10,987, Aug. 28, 1886. 6d.

THE hides or skins are first steeped in a solution of aluminate of soda or potash, containing 1lb. aluminate per gallon. After a few days of this treatment the hair can be removed. The hides or skins, having, by preference, been washed with water, are next placed in a solution containing 2—4 per cent. of boracic acid, and are again washed with water. The hides or skins may be then tanned in the ordinary way or otherwise treated. The treatment with boracic acid may also be used for hides or skins which have been "limed," the boracic acid removing the lime. Sulphate or other soluble salt of alumina may be used along with the boracic acid, and instead of first treating the hides or skins with aluminate of soda or potash, or after so treating them, silicate of soda or potash of a strength of about 18° Tw. may be used.—B. H.

Improvements in Apparatus for Drying Hides, Skins and other Articles or Materials. J. H. Lorimer, Philadelphia, U.S.A. Eng. Pat. 16,411, Dec. 14, 1886. 8d.

THIS invention has reference to improved drying apparatus, whereby the materials to be dried may be passed through the apparatus in a limited time and exposed to mechanical air draughts. For this purpose are provided one or more tubular passage ways or chambers, through which trucks containing the material to be dried are passed. The movement of the vehicle through the chamber is made intermittent, being arrested at certain distances by a suitable stop, and this movement may be made either automatic or controlled by hand. Through the chamber, in an opposite direction to the movement of the vehicle, air currents are caused to pass by a fan or other mechanical means, and this air may be either cold or heated, pure or impregnated with disinfecting or bleaching substances. When desirable, two or more passage ways may be connected together, so that a truck can be run successively through each of them. Drawings are given.—B. H.

XIV.—AGRICULTURE, MANURES, Etc.

On the Assumed Loss of Nitrogen in Mixtures of Superphosphates with Nitre. O. Güssefeld. Chem. Zeit. **11**, 591.

THE author describes experiments to prove that mixtures of superphosphate with nitre suffer no loss of nitrogen, and attributes the reason of the loss in such cases where it has been known to occur to the adventitious presence of free sulphuric acid. He shares the opinion of Peterman in opposition to that of Andouard on this question.—G. H. B.

On the Action of Superphosphates on Nitrates. A. Andouard. Compt. Rend. **104**, 583—585.

THE author's experiments show that mixtures of Chili saltpetre and superphosphates experience a great loss of nitrogen, due to the formation of nitric acid and its subsequent reduction. A marked diminution in organic nitrogen is also found to occur. Mixtures to which ammonium sulphate had been added showed a loss of ammoniacal nitrogen as well. The decomposition starts at temperatures between 25—30° C., but once started it goes on even at 15—12° C. An intimate mixing of superphosphate with Chili saltpetre should, therefore, be avoided.
—F. W. T. K.

On the Relations between Plants and Inorganic Nitrogen Compounds. Dr. H. Molisch (Akademie der Wissenschaften, Wien). Chem. Zeit. **11**, 607.

THE following are the most important results arrived at by the author:—1. Nitrates occur throughout the vegetable kingdom, but are found in much larger quantities in herbaceous plants than in trees. 2. Nitrites, although occurring frequently in the soil, were not found in any of the plants (100) investigated. Nitrites, when absorbed by the plants, are rapidly reduced; and this is clearly the reason why they can never be detected. On the other hand, nitrates may remain without change within the plant-cells for weeks or even months. 3. Even in dilute solutions (0·1 to 0·01 per cent.), nitrites—unlike nitrates—act prejudicially upon some plants. 4. When plants are supplied with nitrogen in the form of nitrites or ammonia, they are never found to contain nitrates; it follows from this that their nitric acid is not produced by the oxidation either of nitrous acid or ammonia. Contrary to the views of Berthelot and André, plants (with perhaps the exception of bacteria) have not the power of converting nitrogen compounds into nitrates. Plants obtain their nitrates simply by absorption; and when they contain more than the soil, the apparent production is only due to a process of accumulation. 5. Diphenylamine dissolved in sulphuric acid is a convenient reagent for detecting nitrates under the microscope; but the reaction is sometimes masked by the action of the acid upon the tissues. 6. The communication contains some further observations upon the localised occurrence of substances which produce a blue colour, both with guaiacum emulsion and potassium iodide starch paste.—D. E. J.

On the Composition of Thomas Slag. Bücking and Linck. Stahl u. Eisen, **7**, 245.

IT has been incorrectly supposed that the crystalline concretions formed in the cellular spaces in Thomas slag and the coarsely crystalline phosphatic slags consist almost entirely of tetrabasic calcium phosphate. If the not too finely-powdered slag be sifted from the fine dust, and the particles of iron be removed by magnets, a further separation can be effected by means of solutions of high specific gravity, and the three most important bodies contained in the slag may be separately obtained in a homogeneous condition suitable for crystallographic observation. The authors found: 1. Slender six sided needles, the ends showing usually a cleavage on which smooth pyramidal faces were not observed. The chemical composition corresponded nearly to the formula $4Ca_3P_2O_8 + Ca_3SiO_5$, so that the phosphoric acid is tribasic in this compound, as is further proved by the yellow precipitate of silver phosphate produced with a solution of silver nitrate. In many respects these crystals resemble apatite and may be considered as closely analogous thereto. 2. A body difficult to isolate from the two accompanying forms, crystallising in the monoclinic system and approximating in composition to the formula $4Ca_3P_2O_8 + 3Ca_3SiO_5$. The crystals are very small, possessing a brilliant lustre and showing a striking dichroism between light blue and intense blue. 3. The principal constituent of the coarsely crystalline phosphatic slags. It crystallises sometimes in thin plates $\frac{1}{5}$ to $\frac{1}{2}$mm. in thickness and 5 to 15mm. in length, sometimes quite clear and colourless, sometimes more or less coloured and cloudy and holding particles of slag. The crystals belong to the rhombic system and correspond nearly to the formula $Ca_4P_2O_9$. Other compounds found in Thomas slag are still under investigation.—G. H. B.

Is Nitric Acid formed in the Higher Plants? U. Kreusler. Ber. 20, 999—1001.

THE author has carried out a series of experiments with potatoes in order to ascertain whether the nitrates which are generally found in growing plants are formed from other nitrogenous constituents during the growth of the plant, or are directly obtained from the surrounding media. The results lead the author to the conclusion that nitrates are not formed during the growth, but that the conditions of their presence must be looked for outside the plant.—G. H. M.

Investigation on the Water Capacity of Soils. Part II. E. Wollny. Agriculturphysik, 1886, 361—378.

FOR the first communication (see *Bied. Centr.* 15, 225), the author arrives at the following conclusions, based on his experiments:—I. The water capacity (measured by volumes) of a soil diminishes with a rise in temperature. The opposite is the case with peat. This diminution is relatively greater the larger the pores in the soil. II. (*a*) The freezing of the water in soils usually causes a diminution in their water capacity. (*b*) This latter result is merely transient in the case of soils of only a slightly cohesive character—*i.e.*, coarsely granular, sandy, poor in vegetable matter. It is of a more permanent nature in the case of soils which show a tendency to form crums—*e.g.*, finely granular, argillaceous soils, or soils rich in vegetable matter. (*c*) The result mentioned in (*a*) is more marked, the greater the quantity of water in the soil, and the more frequently (within certain limits) the frosts alternate with thaws. (*d*) In the case of crummy soils the duration of the diminished water holding capacity may be materially altered, and even converted into an increased capacity if there are frequent alternations of frost and thaw or the crums are loosely aggregated, as this facilitates the breaking up of the crums into a finer state. An explanation of these facts is the increased or diminished aggregation of the soil, resulting from the freezing of the water in the soil. III. (*a*) The water holding capacity of a coarsely granular soil is increased by the presence of even a very thin (3—5cm.) difficultly permeable subsoil—*e.g.*, clay. The more so, the nearer the latter is to the surface. This effect is more marked the greater the difference in water capacity of the upper and lower soils. (*b*) An easily permeated subsoil only slightly increases the water capacity of the soil above it, if the latter is of a finely granular or argillaceous character, but diminishes its capacity if it is more coarsely granular.—F. W. T. K.

Experiments with Beets in Manured Sand. A. Pagnoul. Bull. de l'Assoc. des Chim., 1887, 12.

THE sand employed was free from chalk and organic matter and contained only traces of alumina, clay, iron, potash and phosphoric acid. The object of the experiments was to determine what effect the various fertilisers had on the growth of beets when supplied in various forms. The fertilisers, used either alone or in combination, were (*a*) Chili saltpetre (15·5 per cent. nitrogen), ammonium sulphate (20 per cent. nitrogen), ammonium nitrate and dried blood. (*b*) Potassium chloride (50 per cent.) (*c*) Superphosphate, Thomas slag (7 per cent. P_2O_5), and a natural finely powdered phosphate from the Pernes deposits (20 per cent. P_2O_5.) (*d*) Calcium carbonate. The unmanured sand and that to which no phosphates had been added gave practically no results. The addition of phosphates in all cases produced a marked increase in production, the improvement being least marked with the natural phosphate, and not much better with the Thomas slag. The use of carbonate of lime always caused an increased production. Manuring with coarsely crushed oil-cake gave good results, though the development of the plants was slightly retarded, and the diffusion of the fertilising juices does not seem to go on very uniformly in this case. Deficiency of potash appears to diminish the quantity of sugar in the beets; at the same time the soda salts and consequent impurities show a considerable increase. A deficiency of soda and potash considerably lowers the yield of beets, and consequently of sugar, though the amount of sugar in the beets themselves is apparently not lessened. Experiment shows, that though the beets take up soda, they absorb potash in preference, as the amount of soda in beets grown in the soil to which potash had been added was less than in the cases where the potash had been omitted. The conversion of ammonia into nitric acid was also observed, especially where a sufficient quantity of potash and soda was present.—F. W. T. K.

Employment of the Lye from the (Strontium Method) Sugar Factories as a Manuring Agent. L. Kuntze. Organ des Centr. Verein's f. Rubenzucker Ind. 1887, 125—131.

THE author has been continuing his experiments on the fertilising power of a manure prepared by mixing 25 parts of peat dust with 100 parts of the lye (concentrated to 40° B.). This lye contains 3—2·2 per cent. of nitrogenous matter, and between 13—14 per cent. and 7—8 per cent. of potash respectively. Manuring experiments were carried out with (*a*) the dilute lye as obtained directly from the presses; (*b*) the concentrated lye mixed with peat dust; (*c*) the lye mixed with the mud from the clarifying vats. The dilute lye was employed with good results as a manure for hay, and also for beet and clover fields (directly after gathering the crops) intended for winter wheat and oats. Potato fields should not be treated with the lye, as the potatoes are said to acquire the taste of the lye. Experiments with the second form of manure gave good results with wheat, barley and beets; 4—6 centners of the loose sandy mass were used per morgen. These manures seem particularly to affect the strength of the stalks. The mixture of the hot lye with the mud offers a convenient means of keeping the lye constituents for a long time without loss. Five to six cart loads of this manure per morgen ($\frac{1}{4}$ hectare) gave good results. Large quantities of straw, which only undergo slow decomposition when mixed with ordinary stable dung, are converted into good manure in four to six weeks by treatment with the hot lye.—F. W. T. K.

On the Direct Fixing of Gaseous Atmospheric Nitrogen by Soils. N. Berthelot. Compt. Rend. 94, 205—209.

PREVIOUS experiments of the author have shown that clay and clayey sand soils directly absorb the nitrogen of the atmosphere. The fixing of the nitrogen appears to be brought about by means of micro-organisms, which first take it up. This fixing of the nitrogen goes on, both in a soil free from vegetation, or with grass on it, in the open air and in closed vessels. The above soils were almost free from nitrogen and organic matter. Experiments which the author has now carried out with arable land containing more or less nitrogen, show a similar increase in nitrogen, both when kept under cover and exposed to rain; only in the latter case the increase of nitrogen was greater, no doubt, on account of the more thorough airing of the soil, which assists the development of the organisms. The necessary corrections were made for the small quantities of nitrogen compounds in the air and rain water.—F. W. T. K.

Chemical Investigations on the Feeding and Development of the Silkworm (Bombyx Mori). O. Kellner, T. Kakizaki, V. Matsuoka and P. Joss. Landw. Versuchstationen, **33**, 381—382.

Previous experiments had shown that 1000 caterpillars, fed on a quantity of leaves = 5162·6grms. of dry leaves, ate 2172grms. of dry substance, and digested 771·2 grms. The following experiments were carried out to determine approximately the minimum amount of food necessary to insure the complete development of the larvæ. A batch of caterpillars was divided into three lots. Lot I. received a quantity of leaves equivalent to the following quantities of dry substance:—

Period	I.	II.	III.	IV.	V.
Dry Substance	19·2grms.	72·5grms.	241·8grms.	948·5grms.	3813·5grms.

Lot II. received two-thirds of this, and Lot III. one-half of the quantity. The quantity of food given to Lot I. proved perfectly sufficient. Lot II. was insufficiently fed, and Lot III. still more so. The development of Lots II. and III. progressed very irregularly, and the mortality was greater in each successive lot. The periods of eating, too, were lengthened and the shedding retarded. The insufficient feeding produced a marked effect on the yield of the more valuable portion of the cocoon. The larvæ (5th period) cocoons and butterflies of Lot III. were found to contain a higher percentage of mineral and nitrogenous matter than those of Lot I., though Lot I. yielded a greater amount of fat and non-nitrogenous matter. As in previous experiments other non-nitrogenous matter besides fat was found in the larvæ which were ready to spin.

—F. W. T. K.

Investigations on the Solubility of Gypsum in Solutions of Ammonium Salts. S. Cohn. J. Prakt. Chem. **27**, 1887, 43—56.

Ammonium sulphate, chloride, nitrate and acetate all increase the solubility of gypsum. It is most soluble in solutions of the acetate, next of the nitrate, then the sulphate and finally the chloride. The sulphate probably forms a more soluble double salt; with the other ammonium salts, double decomposition probably takes place. The formation of double salts probably plays a less important part in these cases. For the same weight of salt, the power of reacting on the gypsum is greatest in the case of the acetate, then follows the chloride, the nitrate and lastly the sulphate. This power rapidly increases with dilution.—F. W. T. K.

Manure for Fruit-trees in Winter. Prof. P. Wagner. Bied. Cent. **16**, 357.

For this purpose a mixture of (*a*) potassium chloride (50%) and superphosphate (20%) in equal parts, is recommended. In November the mixture should be strewn over the whole area covered by the foliage and incorporated with the soil, together with ordinary stable dung. In February, Chili-saltpetre (*b*) should be spread over the surface. The latter should also be strewn on the paths if the trees flank or overshadow them. The Chili-saltpetre may be omitted if the trees show a good development both in wood and leaves but do not bear much fruit. If the trees, however, are defective in all three points, the saltpetre is indispensable. The treatment should do equally well for ornamental trees and bushes. A strong fruit tree requires 1kilo. of *a* and ½kilo. of *b*. Weaker trees require proportionately less and in moist ground only half as much of *b*. A large pyramidal tree or wall fruit tree requires about 250grms. of *a* and 150grms. of *b*. Small border trees require 60grms. of *a* and 40grms. of *b*.—F. W. T. K.

Improvements in the Treatment of Manure and other Organic Matters and in the Production therefrom of Ammonia and Residual Products free from Ammonia. W. F. Nast, St. Louis, U.S.A. Eng. Pat. 15,887, Dec. 4, 1886. 6d.

This invention relates to the extraction of the fixed nitrogen in the form of ammonia. It has been found that the presence of sodium chloride greatly facilitates the liberation of ammonia by lime at an elevated temperature.—S. H.

XV.—SUGAR, GUMS, STARCHES, Etc.

The Sugars from Hesperidin and Naringin. W. Will. Ber. **20**, 1186—1190.

The author has previously shown (this Journal, 1887, 449) that naringin and hesperidin are closely related chemically. It was, however, supposed that the former glucoside gave isodulcite on treatment with dilute acid, while the latter yielded dextrose by the same treatment. He has now shown that each substance yields a mixture of isodulcite and dextrose. The former he separated in a crystalline state and analysed, whilst the latter was obtained as phenylglucosazone by means of Fischer's reaction with phenylhydrazine. Isodulcite also gives a compound with this reagent, but it can be easily separated from the dextrose compound by its solubility in acetone.

—G. H. M.

On the Work of the Brushing Cylinders in the Manufacture of Starch. Ztschr. f. Spir. Ind. 1887, 810.

The use of the cylinders is solely to separate from the crushed matter such quantities of starch as have already been set free; they themselves have no freeing action, for Saaren has found as much as 63·5 and 63·6 of starch (calculated on the dry substance) in the residual matter separated by them.—W. G. M.

On Sugar Cane. Journ. Fabr. Sucre, 1887, 15.

According to Schickendantz, the cane contains sugar and invert sugar: colouring matters bleached by sulphur dioxide, precipitated by lime but again dissolved by excess of the precipitant: citric, oxalic, malic acid, and, after longer storing, acetic acid: silicic and phosphoric acids, of which the greater part passes away in the separated solids: alkalis, which are found in the molasses: organic substances: bases, pectin, albumenoids (not precipitated by tannic acid) and various carbohydrates.—W. G. M.

On Alcoholic Polarisation of Sugar-Beet. Ztschr. f. Zucker Ind. 1887, 255.

Degener has found that certain conditions in climate and manuring cause the juice of the sugar-beet to become optically active. This interferes considerably with the exact results otherwise to be obtained with alcoholic polarisation. As a remedy, the alcoholic solution should be boiled, and, before polarising and after cooling, precipitated with lead acetate. Occasionally, as in the case of molasses, reducing substances are present, but, contrary to what has been expressed by others, invert sugar is not one of these products.—A. R.

On Sugar Production without Bone-black. Ztschr. f. Zucker Ind. in Böhmen, 1887, 305.

The disuse of bone-black is considered to be gaining ground. The sugar made thus is equally good, and easily refinable with that in which this material has been employed; and at the Madgeburg Refinery, under the management of Lach, and at that under Miksch, it has

already been very greatly reduced in quantity. It is strongly recommended that the treatment with lime alone, and the removal of the resulting slimes, should be effected before saturation; the addition of the ½ per cent. of lime, mixed with a small quantity of ground and washed coke dust, the remainder of the lime being added to the filtered liquor, gives a firm but porous precipitate, which filters well and is easily freed from sugar. Since the carbon dioxide cannot now decompose the precipitated lime compounds, the juice shows a far higher degree of purity than does that produced in the usual way.
—W. G. M.

Oxidation of Dextrose by Red Oxide of Mercury and Baryta Water. Ztschr. Zucker Ind. 1887, 337.

THE oxidation was conducted by Herzfeld in the same way as with levulose, using red oxide of mercury; the yellow oxide acts too energetically. The oxidation was considered to be complete, when the product ceased to reduce Fehling's solution. The reaction yielded formic and glycollic acids and a mixture of acids, consisting principally of glyconic acid. The same products were obtained by Haberman and Honig in the oxidation of dextrose by hydrated cupric oxide.—G. H. B.

On Molasses Sugar-making according to Le Franc. Bull. Ass. Chim. 1887, 33.

POISSON has described the method employed in Tracy-le-Val for treating 3000ctrs. of beet and 80ctrs. of molasses daily. The cold diluted molasses (containing 8 to 9 per cent. of sugar) is stirred in 8 to 10 charges, with very finely ground quicklime, until 38 to 40 parts are dissolved for each 100 parts of sugar and a dibasic saccharate is produced. The excess of lime is filtered off, and the solution boiled; the tribasic saccharate thus precipitated is filtered, washed once or more by mashing in boiling water, pressed and finally conveyed to the beet-juice. The separated solution still retains one-third of the sugar; it is therefore cooled, saturated with lime as before, filtered, treated with calcium chloride and caustic soda, and again boiled to separate the tribasic saccharate, the liquid being now allowed to run to waste. The cost per 100kilos. molasses should be 19·2fr., which would be made up as follows:—Molasses, 10; chemicals, 2·5; coal, 0·9; wages, 1·65; press-cloths, 1·9; sundries, 2·25frs. The nett profit on the 95 per cent. of the sugar obtained would be 10fr. at present, or by improved methods, 15fr.—W. G. M.

Notes on Saccharates. W. Stromeyer. Arch. Pharm. 1887, **25**, 229.

Barium Saccharate.—Peligot has ascribed to this salt the formula $C_{12}H_{22}O_{11}.BaO$, whereas Stein believes its constitution to be expressed by $C_{12}H_{20}O_{10}.BaO$. The author corroborates the previous formula.

Calcium Saccharate.—According to E. O. v. Lippmann, cane sugar may form mono-, di- and tri-calcium saccharates, thus—$C_{12}H_{22}O_{11}.CaO + 2H_2O$; $C_{12}H_{22}O_{11}.2CaO + 2H_2O$; $C_{12}H_{22}O_{11}.3CaO + 3H_2O$. The author considers that Peligot's is the only method of preparing the pure monocalcium salt—viz., to add alcohol to a clear lime solution containing an excess of sugar.

Aluminium Saccharate.—Freshly precipitated and pure aluminium hydroxide was mixed with a 10 per cent. sugar solution, and the mixture allowed to stand several days. Very little aluminium hydroxide was dissolved.

Chromium Saccharate can be prepared in the same manner as the previous salt.—A. R.

Improvement in the Treatment of Jerusalem Artichoke, to prepare it for use in Distilling in the Manufacture of Glucose and similar Industries. H. J. Haddan, London. From A. Z. Champy, A. N. Champy and L. P. Champy, Brussels. Eng. Pat. 10,164, August 9, 1886. 6d.

JERUSALEM ARTICHOKE in a state of greater or less division is treated with sulphurous acid either alone or in admixture with carbonic acid or nitrogen gas. By this simple operation the juice is clarified, purified and bleached, and at the same time the levuline and inuline of the artichokes are converted into saccharine matter which is readily fermentable. After the reaction, which takes place at 100° C., is terminated the sulphurous acid remaining in the substance is expelled by means of steam, and the juice is filtered. For purposes of distillation the juice may be used as it comes from the filter. For breweries or wine factories it is concentrated to the consistency of a syrup. For the production of glucose it is further bleached by sulphurous acid.—A. J. K.

A Process for the Manufacture of Artificial Gum. M. Strasser, Germany. Eng. Pat. 10,481, August 16, 1886. 4d.

12·5KILOS. of sugar are powdered and boiled with a mixture of 750grms. of fresh cow's milk previously boiled and skimmed, 2·5kilos. of water and 500grms. of colourless 20 per cent. glycerin; into this mixture whilst boiling are strained 25kilos. of 36 per cent. borax, the whole is then cooled to 40° R. and poured into small moulds of sheet iron, in which it sets into hard lumps which may be broken up and used as a gum substitute. The boiling process lasts about three days.—A. J. K.

A Process for the Manufacture of Gum. A. Rossi and C. Hellfrisch, Offenbach, Germany. Eng. Pat. 10,873, August 25, 1886. 4d.

A SUBSTITUTE for gum arabic is prepared as follows:—Starch, water and an acid (preferably sulphuric) are boiled together under pressure until the originally pasty mass begins to get fluid. The material is then neutralised and again boiled, whereby the free starch is converted into gummy matter (gommaline). The product, consisting of dextrin, gommaline, traces of glucose, cellulose and the salts resulting from the neutralisation, is freed from cellulose and the salts in the Taylor apparatus, and is then filtered through animal charcoal. The limpid fluid so obtained may be concentrated by evaporation to a syrup or to dryness. The product "is clear as water, hard like glass, and not hygroscopic," and can be used for most purposes as a substitute for gum arabic, its adhesive power being nearly equal to that of the latter body.—A. J. K.

Improvements in Apparatus for Evaporating the Juice of Beet-root, Sugar-cane, and other Juices or Liquids. P. Labérie, Paris, France. Eng. Pat. 10,911, August 26, 1886. 8d.

FOR the evaporation of saccharine, or other liquors, the author uses a pan which may be in all respects like an ordinary vacuum pan. Hot air is rapidly drawn through the liquor by means of a pump or other exhauster. The air may be heated by waste heat from flues, and drawn into the pan along with the liquor, which is fed in continuously in the form of a spray.—A. J. K.

Improved Process for Converting the Syrups from Sugar-manufacture into Mono-saccharates. F. Harm, Kurtwitz-Prauss, Germany. Eng. Pat. 7259, May 18, 1887. 4d.

THIS invention relates to the treatment of waste liquors in raw sugar factories. "The process consists essentially in conducting the syrups from the first product in a diluted state, and with addition of sugar and sweetening waters, and, if required, further dilution with water, to a saturating station, in the admixture of a sufficient quantity of lime for the formation of mono-saccharate," and in the separation and purification of the sugar by carbonic acid gas.—A. J. K.

XVI.—BREWING, WINES, SPIRITS, Etc.

Recent Advances in Brewing. C. J. Lintner. Dingl. Polyt. J. **263**, 518—525.

ULLIK has investigated the cause of the viscosity or palate-fulness of beer; he criticises Michel's results and conclusions, and lays down the following three conditions as necessary to the investigation of this subject:—

1. A method is necessary by means of which determinations can be made with sufficient exactness, in order to be able to determine the relative viscosity of different liquids.

2. By the aid of this method determinations of the viscosity of aqueous solutions of different substances at varying degrees of concentration must be made, and every substance which occurs in beer and wort as an important constituent must be thus examined.

3. Comparative determinations of the viscosity of different beers and of a number of worts, prepared in various manners, must be made.

Ullik's determinations were made with a modification of the ordinary viscosimeter, the capillary tube of which was of such a size that between the limits of 15° and 28° a difference of 1° of temperature made a difference of only one second in the time occupied by 50cc. of water in passing through the tube. Determinations with varying strengths of solutions of the salts, acids, peptone, albuminoids, glycerin, etc., which are present in beer in quantities less than 1 per cent., showed that these exercised no marked influence on the viscosity, but that it was governed in the case of beers by the dextrin, alcohol and maltose, and in the case of worts by the dextrin and maltose. The determination of the viscosity of a number of beers and worts compared with the quantitative estimation of extract, maltose, dextrin and alcohol gave rise to the following conclusions:—1. The viscosity is the greater the higher the percentage of dextrin, and the latter depends on the method of preparation and the concentration of the wort. The viscosity is certainly not directly proportional to the amount of dextrin present, since it is dependent upon three unequal factors. 2. It is possible to prepare by certain methods infusion worts which have the same viscosity as decoction worts from equal quantities of the same malt. 3. By slow mashing at a low temperature, and prolonged digestion at 50°, a wort is obtained of less viscosity than by mashing quickly at 75°, a result directly opposite to that obtained by Michel. 4. Boiling the thick mash increases the viscosity, the highest result being obtained, together with the greatest amount of dextrin, when the mash is directly boiled. 5. A malt kilned at a high temperature gives, under the same conditions, a wort of greater viscosity than a low-dried malt; in each case, however, this is due only to an increased percentage of dextrin and a decreased percentage of maltose.

Ullik sought to calculate the viscosity of beers, etc., from the data afforded by the determination of maltose, dextrin, alcohol, etc., in the given beer, and the numbers obtained in the above-mentioned estimations of the viscosity of solutions of these substances. He found, however, that there were considerable discrepancies between the calculated and experimental numbers. This he attributes to the presence of small quantities of substances, such as O'Sullivan's α and β-amylans, gums and pectous substances. He has endeavoured to separate and estimate the viscosity of these and similar substances in beer and wort, and has succeeded in obtaining small quantities of a series of bodies with a high rotatory power and viscosity.

Stockheim has introduced a new filter for beer, which is connected with an air-pump and worked under reduced pressure. It is said to filter perfectly bright 20 to 30 hectolitres per hour, without in any way affecting the taste of the beer.

Delbrück has investigated the influence of carbonic acid on the preservation of bottled beer. In former experiments the author proved that carbonic acid exercised an important influence in checking the growth and fermentative power of yeast, and he therefore concluded that carbonic acid might be used as an agent for stopping yeast growth and fermentation at any given point. He has now made experiments to test the efficacy of carbonic acid in stopping the further growth of yeast and the fermentation of the beer when in bottle. The results obtained show that carbonic acid under a pressure of 3 to 4 atmospheres does possess this influence, and completely stops the growth of yeast and prevents the consequent yeast turbidity.—G. H. M.

Extraction of Fusel Oil from Raw Spirit. F. Pampe. Chem. Zeit. **11**, 313—314.

The purification of raw spirits from fusel oils (propyl-, isobutyl-, amyl-alcohols and higher homologues) by purely chemical means has not yet been successfully accomplished. It is known that alcohols, under the influence of chemical agents, undergo decomposition, hence it follows potash, soda and lime must act not only on the fusel oil, but also on the ethyl-alcohol, and the employment of calcined magnesia, as lately proposed, can form no exception. The addition of alkalis is only useful when the raw spirit contains organic acids which must be neutralised in order to prevent the formation of the corresponding ethers, and for the same reason the addition of various acids (sulphuric, acetic, etc.) should be avoided, except when a refined spirit for a special purpose, as for the manufacture of rum, is desired, and even then it is better to mix the ether required for flavouring and the neutral refined spirit together than to use acids in the rectification. The best filter spirit which is found in practice cannot be considered as absolutely pure ethyl-alcohol. In the case of filtered spirit, the aldehyde of the raw spirit has been changed into acetic acid by the oxygen absorbed in the carbon filter, and this, on distillation, forms acetic ether, which must be regarded as a by-product and impurity in the finest spirit. If the acid in the filtrate be neutralised with lime or an alkali, the formation of ether on distillation is avoided and a spirit obtained that contains only a small quantity of by-products. This, however, is seldom done in practice, since customers are accustomed to the agreeable characteristic taste, and suppose it indicates the fineness of the product.

In consequence of the greater acidity of the mash lees the distillate obtained from it has also a characteristic agreeable aroma, which is not quite removed by distillation. But there is considerable difference between the finest filter spirit and the rectified spirit from the press lees. By filtration over wood charcoal, the aldehyde being changed into acetic acid, the retification is made more easy.

In the case of corn spirit the aldehyde remains unaltered, and it is only owing to the greater acidity of the mash on distillation that ethers are formed which mask the disagreeable smell of the aldehydes and fusel oils. The difficulty of the process depends upon the quality of the raw spirit, hence corn spirit is not in favour with refiners. The process of purifying from by-products is rendered more difficult by the addition of acids to the raw spirit than by the acidity of the mash lees, hence this method cannot be recommended.

Neither alkalis, alkaline earths nor acids can be considered suitable for extracting fusel oils from spirit, because they act similarly on all alcohols and do not simplify the process of rectifying. They should be employed only to neutralise the liquors.

As already mentioned, the acetaldehyde is the substance in the raw spirit which renders the extraction of the fusel oil by distillation so difficult. This is owing to the fact that it is readily soluble in the other components of the mixture and boils at 21° C. If the solubility of the acetaldehyde could be lessened and the boiling point raised at a moderate cost, a great improvement would be effected. The conversion of the acetaldehyde into paraldehyde, which is only slightly soluble in dilute alcohol and boils at 125° C., has unfortunately no value in practice, since the acetaldehyde is re-formed on distilling. The only method which is successfully applicable for this purpose is that of oxidising the aldehyde to acetic acid, and this process has the disadvantage already mentioned—*i.e.*, the formation of acetic ether.

The process of spirit filtration also merits attention, and apparently offers a field for inquiry. In large factories where 40—50 filters are in daily use, only one or two filters are replenished daily with freshly-burned

wood charcoal. The amount of fusel oil in the raw product can be estimated and also the quantity contained in the saturated filter. According to this, on steaming the filter a considerable quantity of fusel oil should be liberated (the complete disappearance of fusel oil takes place when superheated steam is used for this purpose). How does it happen that on steaming the carbon so little fusel oil is obtained? This considerable difference is not to be found either as ether or fusel oil in the distillate, neither in the early or final distillates nor in the residue in the retort. What has become of this fusel oil? If we consider the characteristic differences of the alcohols formed by fermentation—*i.e.*, the various amounts of carbon and hydrogen—we are led to inquire whether it may not be possible to convert the higher homologues into ethyl-alcohol by abstracting the group nCH_2. The phenomena apparent on the filtration of spirit lead to the conclusion that the fusel oil is removed by the filter carbon by physical attraction and chemical action.
—J. F. C. S.

Removal of Fusel Oil from Crude Spirits. F. Pampe. Chem. Zeit. **11**, 379.

In reply to a criticism of Pfeiffer (this Journal, 1887, 514), the author remarks that only those defuselation agents are of value which oxidise the aldehydes and reduce the amount of fusel oil. These agents cannot be compared with animal charcoal, whose action is both chemical and physical. He recommends, however, an agent which may be less known. In former years the charcoal was treated with manganese dioxide and sulphuric acid, and a pleasant odour was thus gained for the product. The action of these agents obviously depends on the evolution of oxygen, oxidation of the aldehyde and the formation of ether. The employment of this is not to be recommended, unless it is for the production of a certain sort of brandy.—G. H. M.

Brandy Distillation in Switzerland. Ber. d. k.k. Consulates in Zürich. Österr-ungar. Brauer. Zeit. 1887, 118.

The total production amounts to 50,000 hectolitres, and it is obtained from potatoes, maize and residual matters from the brewery. Only in six distilleries is the raw spirit obtained by a continuous apparatus, and it then contains about 1·32 per cent. of fusel oil. The rectification is mostly insufficient; raw spirit filtered through charcoal showed 0·2 per cent. of fusel oil, rectified by distillation 0·06 per cent., and by filtration with subsequent distillation none. A brandy from a distillery in the Berne district contained 70 per cent. of alcohol and 0·75 per cent. of fusel oil. The residuary liquors are worth about 50cts. per hectolitre. The cost of production of absolute alcohol varies from about 90·6frcs. at small and medium sized works to about 60frcs. at the large establishments.
—W. G. M.

On the Delicacy of Hansen's Method of Detecting the Contamination of Bottom Yeast with Wild Yeast. C. Holm and S. V. Poulsen. Der. Bierbrauer, **18**, 80—82.

This method depends on the rate of development of ascospores in the different yeasts. The authors have made experiments with saccharomyces cerevisiæ, and the following wild yeasts:—S. Pastorianus I, S. Pastorianus II, and S. Ellipsoideus II. At 25° C. the last three form ascospores in 25—28 hours; the first only contains a few after five days. Experiments with mixtures of these, cultivated on plaster of Paris blocks, at 25° C. for 40 hours, were carried out, together with check experiments on pure cultures. It was found that the presence of wild yeast, representing only $\frac{1}{200}$th of the mass, could be detected by observing the formation of ascospores. This degree of delicacy, according to Hansen, is sufficient. The method can be employed with other forms as well, but it will not always be possible to work at the same temperature.—F. W. T. K.

On the Presence of Copper in Wine. Leopold Weigert. Die Weinlaube, **19**, 27—28.

Copper has been detected in wine from vines, the leaves of which had been treated with a solution of copper sulphate, an excellent protective against *Peronospora*. The fear that the drinking of such wine might lead to chronic copper poisoning seems to be groundless, as, according to experiments by Theodor Count G. de la Tour, one litre of such wine only contains 0·000002—0·000026grm. of copper.—F. W. T. K.

XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, Etc.

(*A*) CHEMISTRY OF FOODS.

Artificial Butter from a Sanitary Point of View. M. Schrodt and Fleischmann. Bied. Centr. **16**, 270—277.

The conclusions arrived at may be summed up as follows:—Artificial butter prepared from good fat may be looked upon as perfectly wholesome food; but as it appears to be somewhat less digestible than butter, the latter should be given to invalids and children in preference. No serious objection can, therefore, be raised against the sale of artificial butter, provided (1) that only good fat from healthy animals has been used in its preparation; (2) that it is sold as an artificial preparation, and that the word "butter" is left out of the name of the product, as its presence is misleading; (3) that it is not mixed with true butter for the purpose of preparing so-called "mixed butters" (N.B.—The sale of such mixed butters should be prohibited, as they are mainly prepared for fraudulent sale); (4) that vegetable oils are not used as an ingredient. Official supervision of the artificial butter factories is considered necessary, particularly for the purpose of seeing that proviso (1) is enforced. For though, no doubt, there are a number of honest artificial butter factories, which sell a carefully prepared wholesome article, there is very little doubt but that a large trade is carried on in artificial butter prepared from material of very doubtful quality. The latter is prepared from the fat obtained from unknown sources, and no precautions are taken to exclude the fat of unhealthy or diseased animals. Bad fat has even been used which had to be deodorised by treatment with sulphuric acid and saltpetre. The majority of patents recommend a temperature of 40—50° C. in the preparation of artificial butter. A high temperature is supposed to spoil the flavour. At these temperatures, however, animal and vegetable parasites are able to live; many of the latter would not even be destroyed at 100° C. Such living parasites may, therefore, occur in artificial butter, more especially if pig's fat be employed, and, in fact, Dr. Piper, of Chicago, has demonstrated their presence in artificial butter.—F. W. T. K.

Feeding Experiments with Dried Brewers' Grains. T. Schiller. Bied. Centr. **16**, 282. (Zeitschr. f. Spiritus Industrie **10**, 19.)

The quality and quantity of milk obtained from cows fed on dried returns (proteïn, 22·7 per cent.; fat, 7·8 per cent.; non-nitrogenous extractive matter, 39·4 per cent.) proved highly satisfactory. Analysis of the milk gave—water, 85·37 per cent.; nitrogenous matter, 4·7 per cent.; fat, 3·71 per cent.; milksugar, 5·42 per cent.; salts, 0·80 per cent. The milk, therefore, contained 2·05 per cent. of solids more than average normal milk. Good results were got with the following daily quantities per head (in lbs. German):—3lb. dried returns, 1lb. rye-bran, 1lb. linseed cake, and 25lb. of beets and mushrooms. 9½—10 litres per head of milk were obtained. Horses and ewe-lambs thrive well on returns.
—F. W. T. K.

The Freezing of Normal Cows' Milk. O. Hengold. Milchzeitung, **15**. 461—462.

THE author has analysed milk, samples of which were frozen either slowly or rapidly, whilst being stirred up or left quiet, and has found that the milk-ice always contains more water and less solid residue than the portion which has remained liquid. Frozen milk should therefore always be thawed and well mixed before being analysed.—F. W. T. K.

A New Adulteration of Linseed Cake. Ad. Mayer. Milchzeitung, **16**, 143—144.

THE author draws attention to the presence of the finely-ground husks of ground nuts in linseed cake as a sophistication. In the sample examined the husks were detected microscopically, and as the percentage of cellulose (Zellstoff-Rohfaser) was found to be 22 per cent., whereas good, pure linseed cake only contains 8 per cent. on the average, at least 14 per cent. of ground nut husks must have been added, for the latter do not by any means solely consist of cellulose.—F. W. T. K.

Improvements relating to the Preservation of Alimentary Substances. H. H. Lake. London. From M. Muller, St. Petersburg, Russia. Eng. Pat. 7644, June 7, 1886. 6d.

THE substance to be preserved is placed in a hermetically sealed vessel and heated to a temperature, previously determined experimentally, by means of a steam or hot-water bath. It is then removed and allowed to stand and cool; a succession of similar periods of cooking and cooling follow until the operation of complete cooking is concluded. If, after standing three weeks, the tins in which the material is sealed show no signs of convexity, the operation is deemed successful. When particular flavours are desired to be imparted the material is previously partially cooked by the usual method, which determines the flavour. The specification contains a table showing the temperatures and duration of cooking and cooling experiment has shown to be best or each particular substance.—C. C. H.

Improvements in the Manufacture of Liquid Extract of Coffee. M. Samuelson, New York, U.S.A. Eng. Pat. 17,017, Dec. 28, 1886. 6d.

COFFEE is first steeped in water at a temperature of 40° for three or four hours, "until the aromatic oils and fatty substances are extracted;" the extract so obtained is pressed out from the coffee, which is next saturated with water at 90° and allowed to stand 30 hours, in order to extract the caffeine and kindred substances; after the removal of the resulting infusion, as before, the coffee is finally steeped in boiling water for half an hour or so. The three extracts are mixed together.
—E. G. C.

An Improved Process for Producing Albumen-maltose or Dietary Malt Powder for Food. A. R. Leerbeck and J. F. Holm, Copenhagen, Denmark. Eng. Pat. 6285, April 29, 1887. 4d.

BY special treatment of wheat flour a very pure starch is obtained which is converted, by means of diastase at 65° C., into maltose and dextrose. To the solution of these two bodies are added albumen materials, chloride of sodium and sulphate of lime. The whole is evaporated and the residue dried and ground. From the impure residue of the wheat flour a second quality finishing starch is prepared.—A. J. K.

(B) SANITARY CHEMISTRY.

The Purification of Waste Waters. E. Reichardt. Arch. Pharm. 1887, 252.

THE author has made special experiments on the separation of arsenic from waters.

Separation of As_2O_3 by Lime.—The addition of a slight excess of lime water with rapid stirring produces an immediate deposition of an easily separable precipitate, only 2 per cent of the arsenic remaining in the liquid after treating a 0·1 per cent. solution of arsenic trioxide. The addition of ferric chloride causes complete precipitation, both of arsenious and arsenic acids.

Precipitation by Magnesia.—Even air-dried precipitated magnesium hydroxide added to the liquor left 66 per cent. of the arsenic in solution; other oxides were still less efficient. But when the mixture was warmed to 50—60° C. for some hours, only 1 per cent. of the As_2O_3 was unprecipitated.

Separation of Colouring Matter.—Magnesia was found to be preferable to lime, but the organic matter in the water experimented with was reduced only from 38·4 to 16 parts per 100,000.—W. G. M.

Experiments and Researches on the Use of Zinc-coated Iron Water-Pipes. H. Bunte. Schilling's Jnl. f. Gasbel. u. Wasservers.

AS the result of a discussion at a recent meeting of the German Society of Gas and Water Engineers, the author has collected information from various sources, which tends to show that the use of galvanised pipes should be in no way detrimental to health. According to Dr. V. Ehmann, late director of the water supply in Würtemburg, objection to such pipes cannot be taken on sanitary grounds and he considers them peculiarly suitable for use in the interior of buildings. Dr. Boardmann, of Boston, has found that newly-coated tubes give up zinc to the water flowing through them, but in quantities so small as to be perfectly harmless.
—W. G. M.

On the Increase of Bacteria in Water. G. Wolffhügel and O. Riedel. (Arbeiten a. d. kaiserl. Gesundheits. I. 455—480.)

AT temperatures between 3—23·8° C., water containing traces of nutritive matter showed a greater or less increase in the number of bacteria corresponding to the higher or lower temperature. A *decrease* in the number of germs was invariably observed in water placed in ice. Certain forms of bacteria are not, however, so easily affected by cold as others, for ice usually contains germs still capable of development. According to Gärtner mechanical motion aids the increase of germs even at 6—11° C. In water analysis these facts should be taken into account. Anthrax and typhus bacilli developed well at 30° C., and even at 12—15° C. in water taken from contaminated streams. Water which has satisfactorily passed chemical examination, may for weeks still be capable of providing the conditions necessary for maintaining the power of development of the typhus bacilli. These bacilli were also found to develop well in milk. Cholera germs present in water containing other germs as well were soon superseded by the latter. Cholera germs increased slowly in sterilised milk, but rapidly at 20—24° C. The rapid development of the organisms contained in non-sterilised milk produced an acidity which prevented the further growth of the cholera germs.—F. W. T. K.

Apparatus for and Mode of Clarifying Sewage and Filtering large Volumes of Water. T. Reid, Normanton. Eng. Pat. 4544, April 1, 1886. 8d.

THE sewage is received in tanks, worked three in a series, where it is settled and defecated and the effluent passed therefrom on to filtration areas, which are sometimes used singly and at others in duplicate. The details of the invention are claimed at length under twenty-four heads.—C. C. H.

Improvements in or Additions to Means or Apparatus employed in the Manufacture of Coke for the Desiccation and Incineration of Precipitants or Solids resulting from Sludge or other Substances liable to Putrefy. R. de Soldenhoff, Cardiff. Eng. Pat. 7482, May 23, 1887. 11d.

THESE improvements relate to the system of incineration described in Eng. Pat. 2721 of 1866 and Provisional

Specification 12,259 of the same year, and consist mainly of locating the incinerating furnace between two coke ovens, instead of above the coke ovens as therein proposed. A hopper is placed above the furnace, in which the sludge is received from the truck, and in which it undergoes a preliminary drying before incineration. The specification is accompanied by full drawings showing the disposition of flues, etc.—A. R. D.

XVIII.—ELECTRO-CHEMISTRY.

Improvements in the Preparation or Manufacture of Negative Elements for Voltaic Batteries. D. G. Fitzgerald, London. Eng. Pat. 7636, June 7, 1886. 6d.

This invention relates to an improved method of manufacturing the "lithanode" negative elements, described in Eng. Pat. 4671, 1885, and consists in obtaining the granular peroxide of lead by mixing litharge with a salt or acid, which causes it to set, and passing the plastic mass through a sieve before the reaction is complete; peroxidation is then produced by treatment with chlorine or a hypochlorite. These granules are mixed with plastic oxide of lead, formed into plates and allowed to "set," or placed in a frame of celluloid, or made to surround a suitable negative element such as carbon.—B. T.

Plates without Support, entirely made of Active Material, for Voltaic Batteries. E. Andreoli, London. Eng. Pat. 8842, July 6, 1886. 8d.

These plates are cast from a fused mixture of metallic salts, preferably composed of chloride of lead and chloride of zinc, with a paste of manganese peroxide and hydrochloric acid. To add to the conductivity of the plates, a skeleton of platinum wire or copper wire, contained in a leaden tube, may be surrounded by the fused mass. A leaden frame is then cast round the plates with terminals for connecting them, and the chloride of lead is reduced to a metallic state in a bath of chloride of zinc, the last traces of chlorine being removed by submitting the plates to an electric current. After the plates have been dried they are ready for peroxidation.
—B. T.

Improvements in and relating to Primary and Secondary Batteries. H. H. Lake, London. From W. J. Ludlow, Cleveland, U.S.A. Eng. Pat. 6869, May 10, 1887. 8d.

The time of formation of battery plates is lessened and the amount of their active surface increased by placing them in an air-tight vessel, exhausting the air and then introducing the electrolyte under pneumatic pressure, so that it is forced into the pores of the plates. Two modes of arranging the plates of a battery are described.
—B. T.

Secondary Batteries or Magazines of Electricity. J. S. Sellon, London. Eng. Pat. 3987, Sept. 15, 1881. (IV. Edition of Spec.) 8d.

An alloy of lead with antimony is used to give hardness and durability to the plates, which plates may be composed of perforated strips, tubes or woven fabrics of the above alloy.—B. T.

A Compound for Covering Electric Wires, applicable also for other Purposes. H. W. Merritt, Somerville, Mass., U.S.A. Eng. Pat. 6927, May 11, 1887. 4d.

The ingredients of this compound are silicate of soda, fir balsam or an equivalent, asbestos, sugar, oxalic acid and water.—E. G. C.

A Compound for Covering Electric Wires. H. W. Merritt, Somerville, Mass., U.S.A. Eng. Pat. 6928, May, 11, 1887. 4d.

This compound is an intimate mixture of quicklime, fir balsam, asbestos, sugar, oxalic acid and water.
—E. G. C.

XIX.—PAPER, PASTEBOARD, Etc.

Improvements in Waterproofing and Sizing Paper, and such like Material. C. Meygang, London. Eng. Pat. 7904, June 12, 1886. 6d.

For the purpose of producing a waterproof paper or paper material, the inventor adds to the fibrous pulp in the beater a resinous or fatty size, or a mixture of resinous, fatty and oily substances, such as resin, tallow and petroleum, also starch gelatinised by the action of a solution of caustic alkali. Various mixtures are described for different purposes.—H. A. R.

Improvements in the Manufacture or Treatment of Paper. C. Morfit, London. Eng. Pat. 8148, June 19, 1886. 6d.

The inventor claims that by this method of manufacture, paper is toughened differently from any other now in the market and that this applies more particularly to thin and inferior grades of news and wrapping papers. The soluble matter of sea-weeds such as Carrageen, Agar-Agar, etc., is to be extracted by means of boiling water, and the extract forms the bath with which the paper is to be treated. If desired, resin soap and aluminous cake may be added, but these rather serve to size the paper and increase the rustle than to toughen it.

The above mentioned liquor may be applied either to the web or to the pulp in the engine.—H. A. R.

Improvements in the Manufacture of Paper Pulp and Papier-Mâché. A. Wilkinson, London. Eng. Pat. 8493, June 28, 1886. 6d.

About 1cwt. of any vegetable fibre is placed in a "pit" with water after being sprinkled with quicklime and crystal soda. After a time, this material is removed and placed in a tank containing 1lb. each of sulphuric, hydrochloric and acetic acids to 40 gallons of water, "for loosening the gum and resinous matter in the fibre."

The next process is boiling with "a quantity of crystal soda, soap, common potash and bi-sulphate of sodium, the liquor being boiled for about eight hours, until the resinous and gummy matters are discharged."

According to the patentee, "fibre thus treated is fit for papier-mâché purposes, but any bleaching operation will fit it for ordinary paper. I prefer, however, to prepare a bleach composed of say 1lb. sulphohydrate and sulphuret of barium, 4oz. cyanide of potassium, and 4oz. of oxide of calcium, to which may be added a small quantity of ammonia. These ingredients are broken down in warm water, or I make a bleach of chlorine, chloride of lime dissolved at a boiling heat with 4oz. of soda, a little sulphur, 2oz. of cyanide of potassium and 1lb. of ammonia which is dissolved in 30 gallons of water at about 150° F."

A recipe is also given for what the inventor terms "dry bleach," consisting of sulphuric acid, "salts of lemon or of tin," and "solid ammonia."—H. A. R.

An Improved Method of and Apparatus for Treating Spent Hops for use in the production of Pulp for Paper and Millboard. E. Davies, London, and H. F. Harris, Fleet. Eng. Pat. 8936, July 8, 1886. 8d.

This invention relates to methods and apparatus for cleaning, drying, separating and sifting the spent hops as received from breweries. It is claimed that in this way pulp is produced suitable for the manufacture of paper and millboard.—H. A. R.

Improvements in the Manufacture of Paper Pulp from Moss Peat. A. J. Boult, London. From A. Ubbelohde, Hanover. Eng. Pat. 9178, July 14, 1886. 8d.

The main features of this invention are the manufacture of paper pulp from moss peat by soaking and agitating the same so as to separate it into its component parts, the detached moss leaves being separated from the stalks and other foreign matter by means of a sieve. Secondly, the manufacture of paper pulp from moss peat by means of the rag-engine, in which the said material is either used alone or else together with other stock.—H. A. R.

Improvements in Carbonising Wool, Rags and the like. G. Tolson, Dewsbury, and J. Illingworth, Batley. Eng. Pat. 13,498, Oct. 22, 1886. 4d.

THIS invention refers "to the use and employment of an oscillatory rotary cage or cylinder working horizontally in a machine employed for carbonising fabrics or fibres, so that the said fabrics are more effectually agitated within such cage or cylinder." (Compare this Journal, 1883, 476, and Eng. Pat. 13,497, 1886.)—H. A. R.

Improvements in the Manufacture of Paper from Wood, and in Apparatus therefor. G. Pitt, Sutton. From R. P. Pictet, Geneva, and G. L. Brélaz, Lausanne, Switzerland. Eng. Pat. 5269, April 9, 1887. 8d.

THE inventor claims to be able by his new method and apparatus to reduce to a point of exceptional cheapness the process of manufacturing cellulose from wood by the use of dilute SO_2 solution only, obtained by the combustion of pyrites and condensation of the gas produced in a peculiar tower. A recovery process is also described. For particulars the specification must be consulted.—H. A. R.

Manufacture of Waterproof and combined Water and Fire-proof Paper. L. Bastet, New Jersey, U.S.A. Eng. Pat. 5296, April 12, 1887. 4d.

PAPER stock, and more particularly asbestos stock, is treated during the process of manufacture with a waterproofing composition, consisting of mineral oil, stearic acid, tallow, fucus or Irish moss and caustic alkali at the rate of 5 to 15 per cent. on the material employed. When well saturated, the pulp is to be treated with sulphate of alumina. It is claimed that this composition has a hardening and strengthening effect upon the paper, more especially where asbestos is employed, and makes tougher paper for any use.

—H. A. R.

A Novel Xylonite, Celluloid or Pyroxylin Fabric, suitable for making Shirt Fronts, Collars, Cuffs, Hats and Bonnets, and for other purposes. The British Xylonite Company and Levi P. Merriam, Homerton. Eng. Pat. 7738, May 27, 1887. 4d.

THIS invention relates to the manufacture of a striped or lined xylonite, celluloid or pyroxylin fabric suitable for the above purposes by superposing in suitable order a number of sheets of these substances of the several colours required in the fabric, compacting these sheets into a solid block or body and then cutting this block or body into sheets at right angles to the strata.

—H. A. R.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

On a New Modification of Tannic Acid in the Berries of the Rowan-tree. C. Vincent and Delachanal. Bull. Soc. Chim. 1887, **47**, 492.

To isolate this new modification of tannic acid from the juice of the berries of *Sorbus aucuparia*, the juice was allowed to ferment, for the purpose of decomposing the glucose, then clarified with a little lead acetate and, finally, precipitated by an excess of the reagent. The lead salt was decomposed by sulphuretted hydrogen, and the filtrate evaporated in vacuo. The residue was then extracted with absolute alcohol and the solution again evaporated in vacuo. The tannic acid remained as a thick syrup, which could not be crystallised. It resembles mori-tannic acid, and particularly caffe-tannic acid, but unlike these acids produced in its solutions, a precipitate with lead nitrate of a pure lemon-yellow colour (caffe-tannic acid gives a white precipitate). Gelatin solutions are not precipitated (mori-tannic acid causes a precipitate in them) nor are quinine salts by this new tannic acid, termed sorbitannic acid by the authors. On distillation it yields a thick brown liquor, containing much catechol. In the potash-melt, protocatechuic acid and phloroglucinol were observed.—A. R.

Manufacture of Santonin. A. Busch. J. Prakt. Chem. **35**, 322—341.

Artemisia Cina or *Maritima*, the principal source of santonin, is found on the steppes of Kirghiz, and the cost of carriage is consequently an important item. To obviate this as far as possible a factory has been established at Orenburg, the terminus of the Russian railway; and in 1884 a St. Petersburg firm started a factory at Tschimkent, which is 3200 kilometres beyond Orenburg. The great advantages possessed by the latter manufactory are to some extent counterbalanced by the cost of and loss by transport across the steppes and desert of the necessary hydrochloric acid. In spite of this this factory can place santonin in the market at Hamburg at 18 marks per kilo. The santonin is extracted from the plant by treating the latter with very thick cream of lime. The mixture of seeds and lime is ground with water, the temperature rising so as to drive off the excess of water. Hot alcohol is now added to the cooled mixture, and the extracted juice after removing the alcohol is neutralised with hydrochloric acid. After a few days the crude santonin crystallises out and is washed with cold water. This process depends on the formation of a calcium salt readily soluble in alcohol; this on the addition of hydrochloric acid is split up, and santoninic acid ($C_{15}H_{20}O_4$) set free, which with the loss of a molecule of water is converted into santonin ($C_{15}H_{18}O_3$). In the extraction of santonin a quantity of resinous substance is formed, which on treatment with warm sodium carbonate solution yields a large quantity of santonin. It was found that animal charcoal, which is used to decolorise the alcoholic solution of the crude product, absorbs a considerable quantity of santonin. The amount of pure santonin obtained amounts to 1·8—2·0 per cent. of the plant originally taken.

Santonin crystallises in flattened columns or in feather-like radiating crystalline groups with a pearly lustre, sp. gr. 1·247 at 20°; it melts at 168—170°. It can be sublimed, but with difficulty, since the sublimation and decomposition points lie close together. Hydrochloric acid causes santonin to resinify; it is more soluble in hot than cold acid. Sulphuric acid dissolves santonin, and the solution in strong acid is completely decomposed on warming, with evolution of sulphur dioxide; dilute acid decomposes it with formation of glucose and other substances, showing that it is a glucoside. Nitric acid also dissolves santonin. The hydroxides of the alkalis and alkaline earths combine with santonin, forming salts more or less soluble in alcohol. The potassium salt is only obtained with difficulty in a crystalline state. When potassium hydroxide is mixed with santonin the characteristic carmine-red coloration is produced. The sodium salt $C_{15}H_{19}NaO_4$ is easily obtained in fascicular prisms. Both the sodium and potassium salts are easily soluble in water and absolute alcohol, and are decomposed by acids. The calcium salt, which is formed in the extraction of santonin, crystallises in colourless, very fine silky needles, soluble in water and dilute alcohol, almost entirely insoluble in absolute alcohol; acids decompose the salt with precipitation of santonin, but it is not decomposed by carbonic anhydride.

Barium santoninate $(C_{15}H_{19}O_4)_2$ Ba is analogous to the calcium compound.

When salts of the heavy metals are added to a solution of potassium santoninate the corresponding salts are thrown down; if these salts are boiled with water they are decomposed with formation of pure santonin and the oxide of the metal.

Santonin resin, which results from the action of acid upon santonin, and is most readily obtained by heating santonin with concentrated hydrochloric acid in sealed tubes, appears according to the author to consist of a number of substances which are formed by the decomposition of santonin. This resin prevents santonin from crystallising out, and the best method of separating the resin and santonin is by means of the metallic salts of the latter.—G. H. M.

On the Constituents of Calamus-root. H. Thoms. Chem. Zeit. **11**, 118.

THE author finds that the substance which was supposed to be an alkaloid, and which he had described in a previous communication (*Chem. Zeit.* **10**, 139) under the name calamine, is methylamine. The other constituent of calamus-root, acorin, appears to have the composition $C_{36}H_{60}O_6$. On treatment with dilute acids and alkalis in an atmosphere of hydrogen, or in contact with ferments, it splits up into sugar and the ethereal oil of calamus, according to the equation: $C_{36}H_{60}O_6 = C_6H_{12}O_6 + 3C_{10}H_{16}$. When the aqueous extract of calamus is distilled with caustic potash a large quantity of ammonia is evolved and the distillate is found to contain methyl-alcohol, due to a partial decomposition of the methylamine contained in the root into ammonia and methyl-alcohol. This explains the occurrence (pointed out by Gutzeit) of methyl-alcohol in the distillation-products of calamus-root.—D. E. J.

Short Notice on Saccharine. F. Witting. Chem. Zeit. **11**, 314.

THE author considers that saccharine was obtained by him in the course of the following experiments already in 1879. Paratoluenesulphamide was converted by oxidation into the corresponding acid, parasulphamidobenzoic acid, thus: $CH_3.C_6H_4.SO_2.NH_2 + O_3 = COOH.C_6H_4.SO_2NH_2 + H_2O$. The paratoluenesulphamide (melting point 135°, and not 137° as given by Wolkow) is ground together with pyro-chromate of potash and concentrated sulphuric acid, the best proportions being 4grms. of the amide, 9grms. pyro-chromate of potash, and an excess of sulphuric acid. The last must be added by degrees, otherwise the temperature is raised and the amide melts and is only attacked with difficulty. After about six hours the parasulphamidobenzoic acid was produced, which crystallises from water in small glittering rhombic tablets, melting at 245° C., but commencing to decompose at 235° C. On one occasion when making the above experiment, in addition to the parasulphamidobenzoic acid, there was produced an intensely sweet tasting oxidation product which was not obtained on again repeating the experiment. It dissolved readily in alcohol and ether, but with difficulty in water, and crystallised from various solvents in small, white, wart-like masses, the melting point of which was 111—112° C. A combustion of this body gave no clue to its constitution, probably because it was not thoroughly purified from the amide. Acid sodium sulphite gave with this sweet substance small needle-shaped crystals, insoluble in ether and possessing a bitter taste. If to the aqueous solution HCl and ether be added the original sweet substance is produced again. The author supposes from these results that he had thus prepared parasulphamidobenzaldehyde, whilst from later investigations saccharine is apparently sulphamidobenzanhydride.—J. F. C. S.

Timbo. Chem. Zeit. **11**, 315.

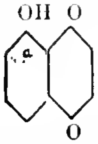
THIS is the name of a new narcotic medicine, the root rind of the *Conchocarpus Peckolti*. The rind appears in the form of tubes or rolls, is bright reddish brown on the outside and yellowish on the inside. The outer and middle rind break off short, but the inner rind has a long fibrous fracture and the interior colour is whitish. It possesses a weak aromatic taste somewhat like cascarilla bark, but has no special odour. A cross section shows an interrupted yellow zone near the outer side, whilst the inner rind is faintly streaked in radiating lines. Some of the cells contain crystals of calcium oxalate.—J. F. C. S.

New Drugs. Chem. Zeit. **11**, 379.

Radix Aristolochiæ Cymbiferæ.—The underground parts of very many Aristolochiæ are distinguished by a particularly strong and unpleasant smell and camphor-like taste. They have been long used as antidotes against snake bites and also in malignant fevers, etc. There are 13 species known in Europe and 14 species in America. The constituents of the Aristolochix have been very little investigated. The root in question, which is a native of Brazil, and occurs in pieces about 10cm. long, the thicker of which are split, is greyish brown, with longitudinal corrugations. A section shows a thick bark and considerable radiated woody tissue. The woody tissue contains wide spotted vessels and also spotted woody fibre. The bark and pith fibres contain much amylum, besides a mixture of yellow resin and ethereal oil in numerous slightly enlarged cells. In outward appearance thin pieces of the drug somewhat resemble *Rad. Aristoloch. long.*, which, however, contains much smaller and less numerous woody-tissue.
—G. H. M.

Constitution and Synthesis of Juglon. A. Bernthsen and A. Semper. Ber. **20**, 937—941.

JUGLON, or oxynaphthoquinone, gives on oxidation juglonic acid or dinitro-α-oxyphthalic acid. Juglon will, therefore, have the following constitution:—



Juglon may be artificially obtained by oxidation of $\alpha_1\alpha_3$ dioxynaphthalene. According to Armstrong, dioxynaphthalene is prepared by the action of chloro-sulphonic acid upon naphthalene dissolved in CS_2. The excess of CS_2 is driven off, the residue dissolved in water, treated with lead carbonate, the lead salt of the sulphonic acid converted into the sodium salt and the latter fused with caustic potash. On adding acid, the dioxynaphthalene separates as a crystalline precipitate. Dioxynaphthalene mixed into a fine paste with water, is oxidised with chromic acid mixture in the cold, the brown precipitate resulting brought on to a filter, washed and extracted with ether. To the ethereal solution a small quantity of petroleum ether is added to precipitate impurities which are filtered off and the filtrate evaporated to dryness. The product on re-crystallisation yields the characteristic needles of juglon, with the peculiar smell of nut-shells. It dissolves in dilute alkalis with characteristic purple colour, and in concentrated H_2SO_4 with an intense blood-red coloration. The other properties are identical with those of the natural product.—J. B. C.

Coccerylalcohol and Coccerio Acid. C. Liebermann and O. Bergami. Ber. **20**, 959—966.

COCCERIN is a crystalline wax obtained from the cochineal insect. This substance may be resolved into coccerylalcohol and cocceric acid. Coccerylalcohol when treated with acetic anhydride yields an acetic ether of the formula $C_{30}H_{60}(O.C_2H_3O)_2$. With benzoic anhydride the benzoic ether of analogous constitution is obtained on oxidising cocceryl alcohol with chromic acid in acetic acid solution; an acid is obtained containing a small quantity of an indifferent substance, probably a derivative of cocceric acid, from which it is with difficulty purified. The acid is pentadecylic acid $C_{15}H_{30}O_2$. Cocceric acid when oxidised with chromic acid yields, in addition to a large quantity of unchanged cocceric acid, a new acid, which may be separated by its much more ready solubility in acetic acid. This acid is likewise pentadecylic acid. The methyl ether has the formula $C_{15}H_{20}O_2CH_3$.—J. B. C.

New Drugs from the Namaqua Country (South-West Africa). Chem. Zeit. **11**, 755—819.

1. *Jon.* It forms transverse sections of a pulpous angular stalk of 2 to 3cm. diameter. The drug swells very much in water and has a sweet taste. It is applied against hemorrhoids. 2. *Naheib.* A thick root covered with a light brown bark. It is useful against diseases of the uterus. 3 *Rabass.* Fragments of stalk and leaves, which taste and smell like oil of thyme. 4. *Blue Shrub.* Fragments of a green bark, which is used as a "healing plaster." The bark is probably derived from *Rhus tomentosa.* 5. *Wild Gourd.* The drug represents fragments of a root, probably from *Cucumis Citrullus Ser.*, which is very common in that country. It is said to produce blisters like cantharides. 6. *Jabi.* A root with a thin reddish skin, the taste of which is sweet at first, but afterwards bitter. It is applied against gonorrhœa. 7. *Ici heib.* A wood-like stalk. 8. *Kau.* Brown seeds of the size of a pea and rich in oil. 9. *The Seeds of Acacia Giraffae.* They are oval and of a greenish-brown colour. There is on each side of the seed a light-coloured circle, the interior of which is brown. The roasted seeds are used as a substitute for coffee and furnish a beverage of pleasant taste and nutritious value. 10. *Klipswilt.* A brown, thickish extract of salty taste, soluble in water. On heating it gives off a smell of urine, and its preparation has probably a mysterious and unpleasant origin. It is applied against diseases of the uterus.—S. H.

The Manufacture of Cocaïne and the Valuation of Coca Leaves. H. T. Pfeiffer. Chem. Zeit. **11**, 783, 784 and 818.

COCAÏNE is manufactured from the dry leaves of the *Erythroxylon coca*, which grows in the valleys of the East Cordilleras of South America—*i.e.*, in the interior of Peru and Bolivia. The fresh leaves contain 0·003 to 0·006 per cent. of cocaïne, which percentage decreases considerably if the leaves are stored any length of time before being worked up. On the other hand, the alkaloid can be transported and kept without decomposition. This circumstance caused the author to devise a simple process for the manufacture of crude cocaïne on the spot, neither Peru nor Bolivia being suitable countries for complicated chemical operations. After many experiments, he hit upon the following plan:—The disintegrated coca-leaves are digested at 70° C. in closed vessels for two hours, with a very weak solution of sodium hydrate and petroleum (boiling between 200° and 250° C.). The mass is filtered, pressed, while still tepid, and the filtrate allowed to stand until the oil has completely separated from the aqueous solution. The oil is drawn off and carefully neutralised with very weak hydrochloric acid. A white bulky precipitate of cocaïne hydrochloride is obtained together with an aqueous solution of the same compound, while the petroleum is free from the alkaloid and may be used for the extraction of a fresh batch of leaves. The precipitate is dried and by concentrating the aqueous solution a further quantity of the hydrochloride is obtained: both can be shipped without risk of decomposition. The product is not quite pure, but contains some hygrine, traces of gum and other matters. Its percentage of alkaloid is 75 per cent., while chemically pure cocaïne hydrochloride ($C_{17}H_{21}NO_4.2HCl$) contains 80·6 per cent. of the alkaloid. The sodium hydrate solution cannot be replaced by milk of lime, nor can any other acid be used for neutralisation. Alcohol or ether are not suitable for extraction. A repetition of the process with once extracted coca leaves gave no further quantity of cocaïne, proving that all the cocaïne goes into solution by one treatment. The same process serves on the small scale for the valuation of coca leaves. 100grms. of coca leaves are digested in a flask with 400cc. of water, 50cc. of $\frac{1}{10}$ NaOH (10grms. of NaOH in 100cc.) and 250cc. of petroleum. The flask is loosely covered and warmed on the water bath for two hours, shaking it from time to time. The mass is then filtered, the residue pressed and the filtrate allowed to separate in two layers. The oil layer is run into a bottle and titrated back with $\frac{1}{100}$ HCl (1grm. of HCl in 100cc.) until exactly neutral. The number of cc. of hydrochloric acid required for titrating back multiplied by 0·042 gives the percentage of cocaïne in the sample. The following are some of the results with different samples of coca leaves of various age:—

	Contained per cent. of Cocaïne.	
Coca-leaves from Mapiri, 1 month old	0·5	Of the weight of the dry leaves.

Coca leaves from Yungas and Cuzco, three years old, contained no trace of the alkaloid, whereas fresh green leaves from Yungas contained 0·7 per cent. of the weight of the dry leaves. The same process is also applicable for the manufacture of quinine from poor quinine bark, with the single alteration that weak sulphuric acid must be used for the neutralisation of the alkaline petroleum extract.—S. H.

Improvements in the Manufacture of Salicylic Acid "Esters." M. v. Nencki, Berne, Switzerland: and C. Kolbe, Dresden, Germany. Eng. Pat. 8018, June 16th, 1886.

THESE compounds, which are termed "salols," as well as their properties and manufacture, have been described at length in this Journal, 1886, 577—578.—E. G. C.

Improvements in the Production of Peptone from Nucleo-proteines. W. Merck, Darmstadt, Germany. Eng. Pat. 8468, June 28, 1886. 6d.

THE inventor claims:—(1) A process of eliminating the nucleïne by digesting the caseïne, for example, with water, dilute acid or dilute alkaline lye, under pressure and at a temperature of 150—170° C, and filtering: (2) a process of eliminating the nucleïne by digesting with dilute alkaline lye at 80—90° C., neutralising with acid and filtering: (3) the elimination of the nucleïne by digesting with a ferment, or ferment-containing substance, acting in an alkaline or neutral solution, neutralising and filtering.—E. G. C.

XXI.—EXPLOSIVES, MATCHES, Etc.

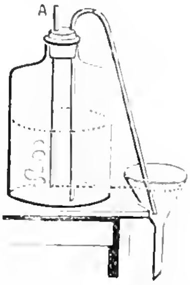
On Roburite. C. Roth. Chem. Zeit. **11**, 538.

ROBURITE belongs to the class of "combined" explosives. It is composed of two constituents, each of which is completely indifferent to friction, detonation and heat. Furthermore, the same can be said of the finished explosive. Thrown into the fire it burns quietly with a light flame, and it can only be exploded by an intensive flame such as is produced by a fulminating-mercury cap. One of the constituents consists of a nitrate, whereas the other is a mixture of the chloro-nitro compounds of the benzene-group. The mixture with the nitrate is in such a proportion that all the carbon burns to carbonic acid and all the hydrogen to water, while the chlorine combines with the alkali. The presence of chlorine in the nitro-compounds has not only a loosening effect on the nitro-groups of the aromatic series, but it increases the explosive power by at least 20 per cent. If roburite be mixed with water it loses its ability of exploding and becomes quite harmless. The principal application of roburite is in coal-mining, as it blasts the coal in large lumps with a small percentage of powder. Neither can it fire mine gases.—S. H.

XXII.—ANALYTICAL CHEMISTRY.

A Contrivance for Automatic Filtration. O. Billeter. Chem. Zeit. **11**, 509.

THE arrangement will be readily understood from the figure. The tube A is open at both ends, and its lower end is adjusted to the level up to which the liquid may rise in the funnel. In order to use the apparatus, the syphon is started by blowing into A, when the operation of filtering



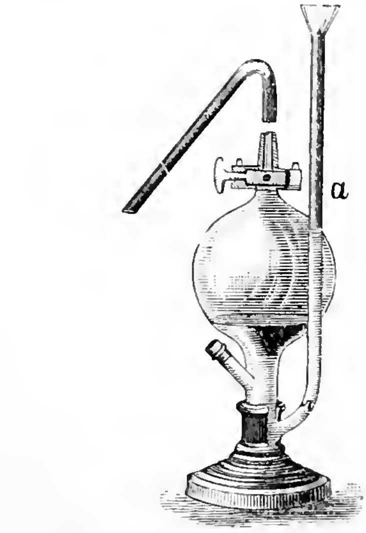
will proceed quite automatically. The liquid in the bottle may be heated if required and the funnel may be connected with a suction pump.—S. H.

A Simple Arrangement for the Regulation of Low Temperatures in Air-baths. M. Ekenberg. Chem. Zeit. **11**, 536.

A METAL CASING, provided with holes, is arranged below the air-bath. The source of heat is a gas burner, the flame of which must end about 4cm. below the bottom of the air-bath, so that the bath is not heated directly by the flame, but rather by warm air, which is partially retained by the metal casing. The key of the gas tap is elongated and made to play on a circular dial, which is graduated empirically. For temperatures up to 50° C. a small flame, provided with a well-fitting chimney, is employed; for higher temperatures a burner with several small flames should be used.—S. H.

A Spherical Gasometer. A. Ehrenberg. Chem. Zeit. **11**, 786.

THE apparatus is of glass, and rests after the fashion of the Gay-Lussac burettes in a wooden support. The accompanying illustration shows the shape given to it



and the gasometer is used in the usual manner, *a* being the tube containing the water to exert pressure on the gas.—S. H.

Improvements in Balances. P. Bunge. Chem. Zeit. **11**, 559.

IT is at first noted that in most balances the sensitiveness of a balance decreases uniformly with increase of load; this is conditioned by steel alloy used for the construction of the beam, which frequently contains pores invisible to the naked eye. To avoid this, and to produce the maximum sensitiveness with mean load, argentan alloy, drawn and rolled, is substituted for steel, which it approaches in solidity, while in elasticity it surpasses nickel alloy and aluminium bronze. In order to avoid vibrations of the pointer, the author adopts a peculiar sectional form, which is found to act better than the usual conical form. A cam arrangement is also described for opening the window of the balance case with one hand and for keeping it open in any desired position. The window opens out towards the observer, and the weights are introduced by side windows; thus the breath of the observer does not injure the balance. In conclusion, an arrangement is detailed in outline for transporting the weights wholly within the balance case, when it may be desired to conduct weighings in vacuo; such an arrangement also avoids a possible diminution in the weights by contact with pincers or the fittings of the box. The arrangement is not as yet completed.

—V. H. V.

A Reaction for Narceïne. P. C. Plugge. Nieuw. Tijdsh. Pharm. Nederl. 1887, 163.

IF a trace of narceïne be warmed with dilute sulphuric acid in a porcelain basin over a water-bath, a beautiful violet-red colour appears as soon as the solution is sufficiently concentrated: continued heating changes it to cherry-red. After cooling, the addition of a trace of HNO_3 or KNO_2 solution, produces bluish-violet streaks in the red liquid. 0·000015grm. of narceïne can be detected in this way.—D. E. J.

Hyposulphite of Sodium and Bismuth as a Test for Potassium. C. Pauly. Pharm. C.H.N.F. 1887, 187.

THIS reaction had already been pointed out by A. Carnot. The author, however, finds that the reaction is a delicate one and applicable as a test for the presence of potassium in very dilute solutions. An alcoholic solution of bismuthic sodium hyposulphite gives with potassium salts a strongly yellow crystalline precipitate of bismuth potassium hyposulphite $K_3Bi(S_2O_3)_3$, which dissolves in water to a colourless solution, but is reprecipitated unchanged by the addition of alcohol. Neutral solutions of sodium, lithium, calcium, magnesium and ammonium salts are without effect; barium and strontium salts give precipitates, but as the colour is white, they are sufficiently distinguished from the potassium precipitate.

The reagent is prepared in two solutions, which are kept separate until required for use. For the one, six molecules of sodium hyposulphite (1488 parts) are dissolved in the least possible quantity of water. For the other, one molecule of bismuth oxide, Bi_2O_3 (468 parts) is dissolved in hydrochloric acid and diluted with acidified water to a volume equal to that of the hyposulphite solution. The procedure recommended is the following:—One or two drops of the hyposulphite solution are placed in a test tube together with the same quantity of bismuth solution, and then 1cc. of water and 10 to 15cc. alcohol are added. If any cloudiness does not disappear on shaking, water is added in drops until the solution becomes clear. To this is added, drop by drop, the solution to be tested for potassium, which, if present, will produce a fine yellow precipitate after some lapse of time. The author obtained an unmistakable indication with 0·00005grm. KCl.—G. H. B.

On the Detection of small quantities of Lactic Acid. W. Windisch. Wochensch. Brauerei, **13**, 214.

LACTIC acid, when heated with potassium chromate and sulphuric acid, is decomposed into formic acid and acetic aldehyde. The solution to be tested is diluted to about 100cc.; 5—10cc. of concentrated sulphuric acid and a little potassium chromate are added and the mixture is submitted to distillation. The vapours are received in warm Nessler's solution. The presence of aldehyde causes a yellow precipitate, small quantities giving only a yellow opalescence. Formic, acetic, propionic, butyric, valerianic, succinic, malic, tartaric and citric acids do not give this reaction.—G. H. B.

A Reaction for Morphine. G. Vulpius. Arch. Pharm. 1887, **25**, 256.

ABOUT 0·00025grm. of a morphine salt is dissolved in a porcelain dish in about six drops of concentrated sulphuric acid, a few centigrams of sodium phosphate added and the mixture carefully heated. White fumes are evolved, and a violet colour appears. Water added drop by drop to the cold mixture produces at first a brilliant red, which, on further addition, changes to a dirty green; if the solution be then shaken with the same volume of chloroform, the latter is coloured blue.—A. R.

On the Detection of Boron in Milk and similar Liquids. M. Kretzschmar. Chem. Zeit. **11**, 476.

AFTER well shaking the milk, 5—6cc. are evaporated to about one-third their bulk in a platinum crucible. A few drops of hydrochloric acid are now added, and the evaporation continued, by means of the non-luminous flame of a Bunsen burner held in such a manner as to play on the top of the crucible. If boron be present the flame is coloured green, but the colour disappears as soon as inflammable gases are evolved. The author maintains that practically all the boron present is evolved in this manner, and that the test is therefore a very delicate one.—A. R.

A Novel Reaction of Chloroform. A. Jolles. Chem. Zeit. **11**, 786.

CHLOROFORM, if not quite free from water, gradually undergoes decomposition under the influence of daylight. An addition of 1 per cent. of alcohol effectually prevents oxidation. Nevertheless, the article in commerce frequently contains a high percentage of oxidisable matters, such as aldehyde, ethylene, and so forth, which may be readily detected in the following manner:—A few grains of chemically-pure potassium manganate (K_2MnO_4) are added to the chloroform to be tested. Pure chloroform does not act on it at all, whereas an addition of about 2 per cent. of alcohol or similar oxidisable matter quickly reduces the manganate, producing yellow-brown spots of potassium manganite (K_2MnO_3). The quicker the reduction and the more intense the spots, the greater was the addition of foreign oxidisable matter. The reaction is expressed by the following equation:— $K_2MnO_4 + C_2H_6O = K_2MnO_3 + H_2O + C_2H_4O$. Potassium permanganate ($KMnO_4$) does not act nearly so rapidly.—S. H.

The Estimation of Acetic Acid in Acetates by direct Titration. A. Sonnenschein. Chem. Zeit. **11**, 591—592.

THE method hitherto in use has been that of Fresenius, which involves a distillation, and to avoid this has been the object of several experimenters on the subject. The author claims to have devised a successful method of direct titration by availing himself of the colour reaction given by methyl-orange (Orange IV.). In testing a sample of sodium acetate, the solution is first titrated with normal hydrochloric acid in presence of phenacetolin in order to determine the sodium carbonate present, after which methyl-orange is added and the addition of acid continued until a red colour shows that the acetate has been decomposed. The sodium carbonate can also be removed by means of barium chloride as a preliminary to titration. The yellow colour of commercial calcium acetate is removed by treatment with animal charcoal; in other respects the procedure is the same as with the sodium salt. Using Fresenius' method as a standard, the author obtains closely-agreeing results by his direct method.—G. H. B.

Notes on the Blue Iodine-starch. F. Mylius. Ber. **20**, 688—695.

IF iodine combines with colourless substances which contain carbon, hydrogen and oxygen, the resulting compounds are, as a rule, either colourless or yellow. Iodine-starch is the only exception known, and this fact seemed to point to the probability of iodine combining with starch in a peculiar manner. The author has now found that the formation of blue iodine-starch is not caused by iodine alone, but by the simultaneous action of hydriodic acid or one of its salts. The properties of iodine-starch well agree with this statement. All the iodine solutions which colour starch blue, contain hydriodic acid or an iodine salt. If a compound be present which destroys hydriodic acid—*e.g.*, chlorine—no blue iodine-starch is obtained. A silver solution decolorises iodine starch; on the addition of iodine, the mixture becomes yellow, but hydriodic acid or one of its salts restores the blue colour. Again, an aqueous solution of iodine does not turn starch blue, whereas the addition of the smallest trace of hydriodic acid is sufficient for the formation of blue iodine-starch. As a consequence, all those substances which convert iodine in hydriodic acid, change yellow iodine-starch to blue. In analysing iodine-starch, it is not sufficient to estimate the total iodine present, but the proportion of iodine to hydriodic acid must also be ascertained. If starch solution be added to a solution of iodine in potassium iodide, acidified with sulphuric acid, a precipitate of blue iodine-starch is produced which quickly collects at the bottom of the vessel. By the titration of the filtrate, the relation of iodine to hydriodic acid can be ascertained; and if the proportion of iodine to hydriodic acid in the original solution is known, the quantities of iodine and hydriodic acid can be calculated which were absorbed in the formation of blue iodine-starch. A series of experiments showed that four iodine atoms and one molecule of hydriodic acid go to form blue iodine-starch, and if the formula $(C_6H_{10}O_5)_x$ represents the molecule of starch, the composition of blue iodine-starch is $[(C_6H_{10}O_5)I]_4HI$. On the other hand, the analysis of iodine-starch dried *in vacuo* yielded: C = 36·14 per cent., H = 5·66 per cent., I = 18·47 per cent. This best corresponds with the formula $(C_{24}H_{70}O_{20}I)_4HI$, which shows at the same time that the formula of starch is $C_{24}H_{40}O_{20}$. Pfeiffer and Tollens's formula, which is the same, and was obtained by another method, thus receives a confirmation. Iodine-starch contains a hydrogen atom which can be replaced by metals. These metallic compounds are obtained in the same way as the iodine-starch, by using the respective iodine salts. Several of these compounds are soluble in water—*e.g.*, the sodium and potassium compound, whereas others are insoluble—*e.g.*, the barium and zinc compound.

—S. H.

An Apparatus for the Estimation of Hydrogen in presence of Marsh Gas in Gaseous Mixtures. F. Hoppe-Seyler. Zeits. Physiol. Chem. **11**, 257.

THIS is an adaptation of the method of Winkler and Hempel, of passing the gas mixed with air over spongy palladium, when only the hydrogen burns, and the marsh gas remains unattacked.—G. H. B.

Titration of Phosphoric Acid with Uranium Nitrate. Ch. Malot. Monit. Scient. 1887, 487.

OXIDE of uranium gives a green lake with cochineal, which property may be utilised for a very exact determination of phosphoric acid. The phosphate is treated according to Joulie's method—*i.e.*, dissolved in HCl, the phosphoric acid precipitated with the citro-magnesium mixture and the precipitate dissolved in dilute nitric acid. A few drops of tincture of cochineal are added, then ammonia until the violet coloration just appears, and this in its turn is made to disappear with 1—2 drops of nitric acid. The solution is now heated to 100°, 5cc. of sodium acetate solution added and the mixture titrated with uranium nitrate. Each drop of the latter causes a greenish-blue zone, which, on agitation, disappears again. As soon as precipitation is complete, the solution assumes a lasting greenish-blue colour, remaining unchanged by excess of the uranium solution. The end-reaction is most distinct. By employing very dilute solutions of uranium nitrate, the determination is rendered very exact. The author uses solutions, 1cc. of which represents 0·002grm. of phosphoric acid. It is necessary to keep the temperature about 100 during the titration.—A. R.

Analysis of Sulphides. Fr. Weil. Ber. **20**, 695—697.

The sulphur in sulphides which are decomposable by hydrochloric or sulphuric acid can be rapidly estimated by passing the sulphuretted hydrogen evolved into a modified Fehling's solution, and retitrating the copper not precipitated with stannous chloride. The Fehling's solution used is prepared by dissolving 39·3375grms. of crystallised copper sulphate, 197grms. of Seignette-salt (sodium-potassium tartrate) and 125grms. of sodium hydrate per litre: this solution thus contains exactly 10grms. of copper. The finely-powdered mineral, wrapped in a piece of filter-paper, is quickly thrown into a flask which contains 50cc. of pure hydrochloric acid and heated on the sand-bath. The sulphuretted hydrogen is absorbed in 50cc. of the copper solution, which were previously diluted with 100cc. of a dilute sodium hydrate solution (70 to 80grms. of NaOH per litre). The distillation is finished in five minutes. The contents of the receiver are filtered, washed and a portion of the filtrate titrated back with stannous chloride. 1grm. of Cu = 0·50393grm. S.—S. H.

On the Detection and Estimation of Vanadium in Minerals and Ores. L. L'Hôte. Compt. Rend. **104**, 990.

In order to isolate the vanadium the author passes dry chlorine over a mixture of 4 parts of the substance with 1 part of charcoal heated in a tube to 250°. In the case of ores which contain arsenic, the mixture must first be made into a paste with oil and then heated to redness. Two Mohr's bulb tubes containing water are connected to the end of the tube. The presence of vanadium is indicated by a red colour in the first bulb due to the formation of vanadic acid, but the fluid remains colourless when only very little vanadium is present. The products of condensation are dissolved in dilute hydrochloric acid, the solution evaporated and the residue tested with a drop of colourless ammonium sulphide, producing the characteristic purple coloration of vanadium sulphide.

For the estimation of the vanadium, the author uses Margueritte's method for determining small quantities of iron, by reduction with zinc and titration with a dilute permanganate solution. The operations must be conducted at a somewhat elevated temperature, and special precautions must be taken in preparing the distilled water used.

If a larger quantity of vanadium be present, the contents of the first bulb will have a bluish-green colour, and in that case the acidified solution is treated with ammonia and evaporated to dryness; the residue, after heating to redness, is weighed as vanadic acid. The author found in bauxite 0·05 and 0·031grm., in Bohemian pitchblende 1·62 and 1·40grm., and in brown ironstone 0·083grm. of vanadium per kilo.—G. H. B.

The Influence of Barium Phosphate upon Acidimetric Analysis. A. Villiers. Compt. Rend. **104**, 1103.

Phosphoric acid can easily be estimated by means of caustic potash or baryta-water, using phenolphthaleïn as an indicator: a phosphate which has a neutral reaction being formed in the first case and insoluble di-barium phosphate in the second case. It might therefore be expected that in the volumetric determination of an acid, no difficulty would be occasioned by the presence of such a salt as di-sodium phosphate; this is true for caustic potash, but it is not so when baryta-water is used.

If HCl is neutralised with baryta-water in presence of phenolphthaleïn, so that a red coloration is produced, and if di-sodium phosphate (which reacts neutrally towards the indicator) is added, the same effect is produced as if there had been an addition of acid—*i.e.*, a further quantity of baryta-water is required to restore the red colour. This reappears at once, but again disappears in five or ten minutes and more baryta has to be added before it becomes permanent, the amount depending upon the relative amounts of di sodium phosphate and barium chloride. In presence of a large excess of di sodium phosphate the precipitate ultimately formed has the composition $BaNaPO_4$.

The main product of the reaction of barium chloride upon di-sodium phosphate is acid barium phosphate:—$Na_2HPO_4 + BaCl_2 = BaHPO_4 + 2NaCl$. On the addition of baryta-water the following decomposition occurs: $2BaHPO_4 + 2NaCl + Ba(OH)_2 = 2BaNaPO_4 + BaCl_2 + 2H_2O$.

Thus a free acid cannot be titrated with baryta-water in presence of Na_2HPO_4, even when phenolphthaleïn (towards which the salt is neutral) is used as indicator. This is also true for the estimation of phosphoric acid in presence of salts of the alkalis; but such determinations can be carried out when caustic potash is employed.

—D. E. J.

Estimation of Copper and Arsenic in Pyrites. R. Nahnsen. Chem. Zeit. **11**, 692.

It is supposed that the pyrites to be tested contain no more than 0·3 per cent. to 0·5 per cent. of copper. The mineral is powdered very finely and 12·5grms. of it are treated in a tall beaker with 10cc. of water and 1cc. of strong sulphuric acid. Nitric acid of 1·4 sp. gr. is then added until there is no further reaction, and the beaker covered with a porcelain dish. The liquid is made to boil, the porcelain dish removed after a few minutes and the beaker shaken very frequently, the boiling being continued until the liquid becomes very thick and commences to separate a yellow salt. The pasty mass is then dissolved in warm water. The solution, after cooling, is transferred to a 250cc. flask, filled up to the mark and 200cc. (=10grms. pyrites) are filtered through a dry filter. The solution, now free from silica and lead, is treated with sulphuretted hydrogen for several hours, until the precipitate forms small lumps and the liquid is quite clear. The former is then rinsed into a beaker, which contains a strong solution of sodium sulphide in sufficient quantity to dissolve all the sulphur on boiling. The solution is diluted with hot water, allowed to settle for some hours and filtered. The solution contains all the antimony and arsenic, whereas the cupric sulphide is on the filter and can be estimated as cuprous sulphide. By the addition of an acid to the sodium sulphide solution, antimony and arsenic is precipitated, the latter of which is extracted from the washed precipitate by ammonia.

—S. H.

On the Determination of Arsenic as the Pentasulphide. Le Roy W. McCay. Amer. Chem. Jour. **9**, 174—179.

The author strongly recommends that where arsenic has to be determined in an arsenate, it should be estimated gravimetrically as follows:—The solution containing from 0·1 to 0·3grm. of arsenic is placed in a flask with a well-fitting stopper, the capacity of the flask being about 200cc. It is then acidified with hydrochloric acid and diluted with freshly-boiled water until the flask is nearly full. H_2S gas is then passed in to saturation, the stopper inserted and fastened down, and the whole placed in a hot water bath for an hour. At the end of that time all the arsenic will be precipitated as As_2S_5, containing, as the author's experiments show, no free sulphur.—S. G. R.

Estimation of Hydrogen Peroxide. H. Thoms. Chem. Zeit. **11**, 118.

The two following methods for the determination of hydrogen peroxide are recommended as being both rapid and accurate:—(1.) The apparatus used is Fresenius and Wills's apparatus for the estimation of CO_2. Pour in 5cc. of the solution of hydrogen peroxide, and introduce a small tube nearly filled with coarsely-powdered MnO_2, without allowing the solution to touch this. Concentrated sulphuric acid is poured into the second flask, and after a little of this has been drawn over, the apparatus is shaken so as to bring the mixture into contact with the MnO_2. Oxygen is freely given off, and after the evolution of gas has ceased a stream of air is drawn through the flasks in the usual manner, after which they are weighed. The loss of weight indicates the amount of oxygen evolved; one-half of this comes from the hydrogen peroxide, according to the equation $MnO_2 + H_2O_2 = MnO + H_2O + O_2$. (2.) The second method depends upon the fact that hydrogen peroxide liberates from acid solutions of potassium iodide a corresponding quantity of iodine, which can then be titrated with $Na_2S_2O_3$. 0·5grm. of KI, 1grm. of dilute sulphuric acid (1:4) and 50grms. of water are heated to about 40°; to this is added 0·5cc. of the hydrogen peroxide (or, better, 5cc. of the solution diluted to a tenth of its previous strength) and the whole is allowed to stand, with frequent shaking, for about five minutes, after which it is titrated with decinormal thiosulphate solution. On further heating to 40° a slight brown coloration is produced, which is again destroyed by adding more thiosulphate. The re-action is as follows:—$H_2O_2 + 2KI + H_2SO_4 = K_2SO_4 + 2H_2O + 2I$; $2Na_2S_2O_3 + 2I = 2NaI + Na_2S_4O_6$. Thus 2I corresponds to H_2O_2 or $2Na_2S_2O_3$; and consequently 1cc. of decinormal thiosulphate is equivalent to 0·0017grm. H_2O_2.—D. E. J.

Notes on the Estimation of Morphia. H. Goebel. Chem. Zeit. **11**, 508.

5—10GRMS. of opium are digested with 110cc. of water at 55° C. and from 4 to 5grms. of quicklime are then added. The mass is allowed to stand with frequent stirring for one hour. It is then filtered, and 50cc. of the filtrate are shaken with 5cc. of 95 per cent. alcohol, 25cc. of ether and 3grms. of ammonium chloride. The mixture is allowed to crystallise over-night. The ether is then carefully decanted through a filter, the latter washed with pure ether, and the alcholic liquid is at last filtered into a graduated cylinder, using the mother liquor to bring the crystals on the filter. They are washed with cold water, until the filter is colourless. For every 10cc. of water 0·01grm. of morphia is allowed. The filter is dried at 100° C. and the weight noted down. The crystals are then removed from the filter and the latter is moistened with dilute sulphuric acid, and afterwards washed with water, until the washings give no reaction with starch solution and iodic acid. The filter is again dried and weighed, and the difference of the two weighings is the amount of morphia in the opium.

—S. H.

On the Estimation of Nicotine in Tobacco Extracts. Dr. R. Kissling. Chem. Zeit. **11**, 605.

THE following additional details are given by the author in further explanation of the method of determining nicotine, previously published by him (*Chem. Zeit.* **9**, 1336). 100grms. of the extract is a convenient quantity to work with; this is distilled in a current of steam until the contents of the distillation flask have diminished by about 25 per cent. (and not, as previously stated, until the volume is reduced to 10—15cc.). The flask must be very carefully heated over wire gauze, otherwise it may easily become over-heated owing to the precipitation of insoluble matters. It is found advantageous to grind up the mixture of ammonium and nicotine sulphates with 1cc. of concentrated caustic soda solution, then to add 40—50grms. of sand and as much powdered lime as is required to convert the whole into a pulverulent mass.—D. E. J.

Quantitative Determination of Lignin in Paper. C. Wurster. Ber. **20**, 808—810.

THE author has taken advantage of the fact that paper containing ground wood turns dimethylparaphenylenediamine an intense magenta colour, whilst paper made from linen or cotton fibre, or with chemically treated wood cellulose, only turns this substance slightly yellow. By taking a series of hand-made papers containing known amounts of ground wood the author was able to make a colour scale, the colours of which correspond to the colours given with dimethylparaphenylenediamine by papers of known strength. Test papers with the latter substance are employed, and since these and the scale can be carried on the person, this method forms a most convenient and quick means of estimating both qualitatively and quantitatively the amount of ground wood in paper. The author has also determined the amount of normal iodine solution corresponding to the scale colours.—G. H. M.

Chemical Examination of Silk. J. Persoz. Monit. Scient. 1887, 597.

DEVILLE first suggested that the quantity of pure silk present in silk fabrics might be estimated by determining the amount of nitrogen, and the method has been worked out by Moyret, who takes 2grms. of the material, bleaches, dries, cuts it up fine and determines the nitrogen by Will and Varrentrap's method. Moyret concluded, after making numerous analyses, that silk-fibre contained 17·6 % of nitrogen. The author recommends, in order to prevent loss in reducing the material to a finely-divided state, that it should be immersed for a few moments in HCl diluted with two to three times the volume of water, then exposed to the air for some time and dried at 120°, when it can easily be reduced to an impalpable powder. He now finds that silk contains 18 % of nitrogen and bases his calculations upon this result.

Silk fabrics often contain tin salts (especially the chloride): these can be detected by burning the silk and examining the ash before the blowpipe. Or the material may be warmed in a test-tube with just enough concentrated HCl to dissolve it completely, the solution diluted with water and H_2S passed through, when the presence of tin can easily be detected. To distinguish between pure mulberry-silk and the wild or Tussah-silk, the material under examination may be boiled for a minute with zinc-chloride solution of 45° B., which dissolves the mulberry-silk without appreciably attacking the other.—D. E. J.

Extractum Aconiti. A. Kremel. Pharm. Post. 1887, 253.

THE alkaloids in extract of aconite can best be estimated as follows: 7·5grms. of the extract are weighed into a porcelain dish, dissolved in 10cc. of water and carefully transferred, with 5cc. of water, to a flask graduated to hold 150cc. 95% alcohol is added in small quantities, with frequent shaking, until the flask is filled to the mark: it is then allowed to stand for three to four hours, after which 100cc. (=5grms. of the extract) are filtered from the precipitated albuminous matters. 25cc. of water are added to the filtrate, which is heated on a water bath to drive off the alcohol: after standing for a few hours, so as to allow of the precipitation of resinous matters, the liquid is filtered through a wetted filter, which should be carefully washed. The acid solution thus prepared (20—25cc. in volume) is shaken up with 15—20cc. of chloroform in order to remove free organic acids and any resinous matters which may still be present. The solution is separated from the chloroform, made alkaline with potassium carbonate and shaken up first with 15cc., then with 10cc. and, lastly, with 5cc. of chloroform. After each addition of chloroform, the mixture is allowed to stand for two or three hours; the chloroform-solution of the alkaloids is then transferred to a crystallising-dish, allowed to evaporate spontaneously and the residue dried over H_2SO_4. Other extracts can also be examined in this way.—D. E. J.

A Scheme for the Examination of Glue. R. Kissling. Chem. Zeit. **11**, 691 and 719—720.

(*a*) *Estimation of Water.*—2 or 3grms of glue shavings are dried at 110° to 115° C. until the weight remains constant. (*b*) *Estimation of Ash.*—The residue from the test *a* is burned in a platinum crucible, if necessary with the addition of a drop of nitric acid. (*c*) *Qualitative examination of the ash.*—The properties of the ash give a clue to the origin of the glue. The ash from bone-glue fuses by the heat of the Bunsen burner: its aqueous solution is neutral and it contains phosphoric acid and chlorine, whereas the ash from leather-glue does not fuse, owing to the presence of caustic lime. Leather-glue has an alkaline reaction and is free from phosphoric acid and chlorine. (*d*) *The determination of the Acid.*—30grms. of glue are suspended in 80cc. of water and allowed to stand for several hours. The volatile acids are then driven over by a current of steam. As soon as the distillate amounts to 200cc., the distillation is discontinued and the contents of the receiver titrated with standard alkali. Sometimes the distillate contains sulphurous acid, in which case the receiver should contain a known amount of standard alkali. (*e*) *Capacity of Drying.*—The solution of glue freed from volatile acids is made up with water to 150grms. and heated on the water-bath. 10cc. are spread on a watch-glass, and allowed to stand in a room which is free from dust and not exposed to frequent changes of temperature. The change of the glue jelly is observed for several days, and if possible the behaviour of this jelly is compared side by side with glue jellies of known quality, as the temperature and amount of moisture in the air has an influence on the consistency of the jelly. (*f*) *Foreign Matter.*—The rest of the glue solution from the test *e* is diluted with hot water and transferred to a cylinder holding 1000cc., and provided with a cc. scale. After filling up to the top, the contents of the cylinder are allowed to subside for 24 hours and the settlement noted down as "foreign matter." (*g*) *Smell.*—The smell of glue differs very much. Leather-glue smells least. Other glues do not smell in the solid state, while their jelly has an unpleasant odour. The above table shows the result of the examination of different kinds of glue.—S. H.

No.	Water per Cent.	Ash per Cent.	Qualitative Properties of Ash.			Volatile Acids per Cent.	Capacity of Drying.	Foreign Matter.	Smell of		Quality of Glue.	Price per 100kilos. Mark—*i.e.*, Shillings.

Methods of Analysing Opium. E. Dieterich. Pharm. C. H. N. F. 1887, 219.

THE so-called "Helgenberger" method of estimating morphia in opium and its preparations was introduced by the author. Objections were raised to it, mainly on account of its difficulty, by Schlickum, who proposed a modified method. In a long paper, containing a large number of analytical results, the author compares the two processes, and shows conclusively that Schlickum's method is no improvement upon his own.—D. E. J.

Estimation of Morphia in Opium. J. Biel. Pharm. Zeit. Russl. 1887, 241.

THE author has compared the best-known methods—those of Flückeger, Hager and Dieterich—and he draws from his analytical results the conclusion that Dieterich's (the "Helgenberger" method—see previous abstract) is the best, because (1) it gives the largest yield of morphia; (2) the precipitated morphia is the purest; (3) the method is an easy and convenient one; and (4) the results obtained agree well with one another.—D. E. J.

Determination of Starch in Paper. G. Schumann. Papier Zeitung, 1887, 389.

THE author finds that diastase (malt extract) is a good solvent for the starch. A strip of the paper weighing 5grms. is boiled four times with dilute alcohol in an Erlenmeyer flask, in order to remove resins and soluble salts, the alcohol being changed every half-hour. The extract is filtered through a parchment filter in order to retain any fibres held in suspension; the strip of paper and the contents of the filter are then dried at 100° until the weight becomes constant. They are next digested with the malt extract at 65—70° until the starch is all extracted, then washed with hot water, again dried at 100° and weighed. The loss gives the amount of starch.

To prepare the malt extract, pour a mixture of two litres of water and four litres of glycerine over 3·5kilos. of freshly-pounded malt; let it stand, with occasional stirring, for eight days, then press and filter. The solution keeps well; five drops of it are sufficient to dissolve 1grm. of starch.—D. E. J.

Quantitative Determination of Theine in Tea-leaves. Lösch. Pharm. Zeits. Russ. 1887, 177.

10—20grms. of tea-leaves are twice extracted with boiling water. The leaves are filtered off and washed

with hot water until the latter is no longer coloured. The filtrates are then evaporated with 1½ times the weight of magnesia, calculated on the weight of tea-leaves employed. The residue is finely powdered, extracted with chloroform, the latter evaporated off, and the residue dried at 100—105° and weighed. All the theine is thus obtained in a perfectly colourless state.
—A. R.

Notes on Sugar Analysis. Seyffart. Neue Zeits. f. Zuckerind. 1887, 150.

THE article first treats on a method for taking samples of raw sugar, particularly as regards the systematic mixing thereof. For igniting, without addition of sulphuric acid, vaselin free from ash may be advantageously employed. 5grms. of the sugar are weighed into a platinum dish. covered over with vaselin and the dish is gently heated and finally made red-hot. The author also refers to the determination of alkalinity of juices, particularly as regards the use of normal alkaline solutions and indicators of constant composition. For the determination of caustic lime in burnt lime, 4·667grms. of the powder are weighed off, boiled for 30 minutes in a 250cc. flask with water, and mixed with a solution of 80grms. of sugar in 150cc. of water, previously warmed to 65°. The mixture is well shaken, and the solution filled to the mark, filtered after 5—6 hours and 50cc. titrated with normal acid solution. Treble the number of cc. employed gives the percentage of caustic lime present.—A. R.

Determination of the Melting Point of Paraffin. L. Weinstein. Chem. Zeit. 11, 784.

MANY methods exist for the determination of the melting point of paraffin. Although the matter is very simple, discrepancies in the test are very frequent owing to different points being observed as the point of fusion. The Halle-Association prescribes to melt a small piece of paraffin in warm water, observe the temperature of the water while cooling, and note that point as the melting-point when the paraffin-drop shows the first signs of solidification. In America a sufficient quantity of paraffin is melted in a small beaker and allowed to cool, stating that point as the melting-point when the mass commences to be stiff. Again in Scotland, the paraffin is melted in a small crucible and the liquid mass is stirred with a thermometer, until half of it has solidified. At this point the temperature is said to remain constant for a few moments. The author tried to ascertain the melting-point in the manner usually employed in scientific laboratories—viz., with a capillary tube—and found that the results obtained are very concordant indeed. He recommends this method as the simplest, and it is the method most generally used for other substances. The results agree with those of the Halle and American method, but are lower than those obtained by the Scotch process by 2° C.—S. H.

Quantitative Examination of Strychnine and Brucine. G. Holst and H. Beckurts. Pharm. C.H.N.F., 1887, 119.

THE authors have now discovered a method involving the employment of potassium ferrocyanide, which gives absolutely certain results. A similar method had not hitherto given good results. On adding to a strong hydrochloric acid solution of both alkaloids (not too dilute; about 0·5—1%) a solution of potassium ferrocyanide till a sample of the filtrate produces a blue colour on ferric chloride paper, the whole of the strychnine is separated as strychnine ferrocyanic acid $C_{21}H_{22}N_2O_2H_4Fe(CN)_6$, whilst the brucine remains completely in solution. By using a standard solution of potassium ferrocyanide, the strychnine may be easily determined volumetrically. 244 parts of potassium ferrocyanide are equivalent to 334 parts of strychnine. In a mixture of strychnine alkaloids, the total of the strychnine and brucine would in the first place be determined by gravimetric analysis, then the strychnine as above and the brucine would be obtained by difference.—W. R.

Testing of Bitter Almond Water. H. Beckurts. Pharm. Centr. H. N. F. 8, 131.

BY adding magnesium hydroxide to bitter almond water until the solution just becomes opalescent and then titrating with decinormal silver solution, after the addition of a few drops of potassium chromate, the results obtained are always too low. An aqueous solution of hydrocyanic acid gives accurate results when similarly treated. The author considers the above inaccuracy to be due to the slowness with which the benzaldehyde hydrocyanide is decomposed with formation of magnesium cyanide, and not to the gradual decomposition of the latter by the silver chromate. By allowing the bitter almond water to stand for half an hour after the addition of the magnesium hydroxide better results are obtained; while by replacing the magnesium hydroxide by magnesium acetate, according to Kubel's suggestion, the reaction takes place quickly and uniformly.—C. A. K.

The Examination of Officinal Bromides. G. Vulpius. Pharm. Centr. H. N. F. 8, 133.

ACCORDING to the Pharmacopœia, the bromides of potassium, sodium, and ammonium are tested by the amount of decinormal silver solution needed to completely precipitate 0·3grm. of the salt. This method is no guard against the presence of chlorides in sodium or ammonium bromide, should they contain potassium bromide as well, owing to the higher molecular weight of the latter bromide. Ammonium or sodium bromide contained in potassium bromide would, owing to their lower molecular weight, have an opposite effect on the results.
—C. A. K.

Examination of Lead-plaster. A. Kremel. Pharm. Post. 20, 190.

LEAD-PLASTER is readily tested by extracting it with ether. Plaster prepared from oleïc acid, consisting of lead oleate, is almost completely soluble in ether; that from olive oil contains 17—20 per cent. of lead salts insoluble in ether (lead stearate and palmitate), and that from pig's fat 40—50 per cent.—C. A. K.

The following letter, addressed to Mr. DOUGLAS COGHILL, *M.P. for Newcastle-under-Lyme, has been handed to us for publication:—*

NORTH STAFFORDSHIRE.

DOUGLAS H. COGHILL, ESQ., M.P.

HONOURABLE SIR,—Having read in the newspapers a report of the statements made by representatives from the South Wales district to the Home Secretary on the Coal Mines Regulation Bill, we, as certificated managers in North Staffordshire—the most dangerous, fiery, and dusty district in the kingdom—desired to attend as a deputation to explain our views and give our experience to Mr. Matthews before the rules of the new Act as to blasting are settled; but we understand it is too late to arrange for the reception of such a deputation, and we, therefore, beg you to take an opportunity of conveying to the Home Secretary a digest of what we should have said.

Blasting by means of ordinary powder has been given up as quite unsafe in some of the mines in this district for years; but since the introduction of the gelatinous compounds and the water cartridge with electric firing apparatus, we have been employing the system for nearly two years, and at this moment its adoption is daily increasing, and not one single case of accident has occurred, while some 200,000 shots have been fired.

In the question of cost, the new system compares favourably with the use of powder and old-fashioned fuse, and on the average the expense is no greater, while the coal is got in an equally good, if not better, condition; but above all is the sense of security experienced by the workmen and managers, owing to the killing of the flame on the explosion of each shot.

We consider that the clauses on shot-firing in the bill as drawn are wisely drawn, and with some slight modifications should stand.

We object to the permission of the employment of gunpowder in any ventilating district where gas has been found issuing or accumulated within four weeks previously, on the grounds—

1. That it is wholly unnecessary.
2. That it would be unfair to allow it in one district and not in another.
3. That it is certain very soon to result in serious explosions and loss of life.

We have the honour to subscribe ourselves, Honourable Sir, yours respectfully,

THOMAS ROBSON, Manager, Podmore Hall Collieries, Mr. Craig's Collieries (late M.P.)
W. ROBSON, Duke of Sutherland and others, Great Fenton.
BENJ. JOHNSON, Audley Coal and Iron Co.
WILLIAM MEADOWS, Madeley Coal and Iron Co., Ltd.
WILLIAM SCOTT, The Butterley Co., Silverdale.
ENOCH EDWARDS, Miners' Agent, President of Midland Miners' Federation.
JAMES POTTS, Manager, Mossfield Colliery, Longton.
SIMON BARKER, Mossfields and Berry Hill Collieries.
EDWARD MILLINGTON, Harrison and Woodburn.
WILLIAM BRIDGETT, Chatterley Iron Co., Ltd.
J. CADMAN, Stainer & Co., Apedale Collieries.
On duplicate letter.
W. OSWALD, Talk-o'th'-Hill Collieries.

The above certificated colliery managers are directly and personally responsible for the lives of over 14,000 miners.

1885.—Coals raised in North Staffordshire, 4,815,000 tons.

Trade Report.

(From the Board of Trade Journal.)

BOARD OF TRADE NOTICE.

THE INTERNATIONAL EXHIBITION AT BARCELONA.

With reference to the notification on p. 522 of the 11th Number of the *Journal*, a communication, dated the 30th July last, has been received from the Foreign Office, to the effect that Mr. Frederick Witty, unpaid British Vice-Consul at Barcelona, who is engaged in business at that port as a commission agent and broker, is ready to act as agent for British exhibitors at the Exhibition proposed to be held at that place next year, and to afford information in regard to the Exhibition to persons who may wish to obtain particulars with the view to taking part in it.

TRADE BETWEEN SPAIN AND THE UNITED KINGDOM.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

SWITZERLAND.

Classification of Articles in Customs Tariff.

(*Note.*—Quintal = 220·4lb. avoirdupois. Franc = $9\frac{6}{10}$d.)

The following decisions affecting the classification of articles in the Swiss Customs Tariff have been given by the Swiss Customs Authorities during the month of June last:—

Peroxide of manganese; extract of oak and of oak bark, liquid. Category 16, duty 30 centimes per quintal.

Dualine (nitrite of soda); extract of oak and of oak bark, solid. Category 17, duty 1 franc per quintal.

RUSSIA.

Recent Customs Decision.

(*Note.*—Poud = 36lb. avoirdupois Rouble = 3s. 2d.)

The duty on ammonia and all salts of ammonia shall be raised as follows:—

Section 127. Ammonia and all salts of ammonia.

1. Salammonia (chloride of ammonia), carbonate of ammonia, and all salts of ammonia, excepting sulphate of ammonia, in a raw and refined state, as well as liquid ammonia, 1 rouble 20 copecks per poud.

2. Sulphate of ammonia, 50 copecks per poud.

NEW CUSTOMS TARIFF OF BRAZIL.

The following is a statement of the rates of import duty now levied under the New Customs Tariff of Brazil, which came into operation on the 1st July last:—

(*Note.*—Kilogramme = 2·201lb. avoirdupois. Litre = 0·22 Imp. gallon. Milreis = 2s. 3d., nominal value.)

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS

OPENINGS FOR BRITISH TRADE IN MEXICO.

The following information, respecting openings for British Trade in Mexico, is extracted from a report, dated the 16th of July last, by Mr. Lionel Carden, Her Majesty's Minister at Mexico, which appeared in No. 202 of the Foreign Office (1887) Annual Series of "Diplomatic and Consular Reports on Trade and Finance":—

"In view of the great field which exists for agricultural and mining enterprise in this country, a fact which is at last beginning to be realised abroad, the machinery trade may be considered to be as yet in its infancy, and offers special inducements to business men, in that (most of the articles being free of duty) not so much capital, comparatively speaking, is required as in other businesses.

"In a secondary degree, it is probable that houses for the sale of English hardwares, which have been almost entirely superseded in this country of late years by similar German and American goods, might be established with a good chance of success.

"Another class of business in which English capital might be profitably employed, is that of ore-buying for shipment to England. There are already two American agencies established in the capital for that purpose, but the cheaper rates of freight to England, and the lower cost of reduction there, would enable English firms to compete with every prospect of success. This business is likely to be one of very great importance in the near future, in view of the large number of mines which are at present unworked on account of the heavy cost attendant on the establishment of reduction works, and from which large quantities of ore of moderate ley might be exported.

"In conclusion, it may be said that if English manufacturers are contented to leave the distribution of their goods in Mexico to merchants of foreign nationalities, though they may continue to retain a certain share of the trade, a considerable part of what they might have will unquestionably be wrested from them by their more active competitors. The superiority of English manufactures is not so unquestioned nowadays as to ensure for them a constant demand in foreign markets, and the indifference of the manufacturers to the special requirements of their foreign customers stands out in strong relief to the solicitude shown by American and German merchants to anticipate their wants and provide for them.

"With equal advantages as regards the prime cost of their productions and the expense of placing them on the market, it only requires the same tactics of advertising and canvassing, which have been so sucessfully employed by other nationalities, to secure to British merchants their due share in the trade of Mexico, the future importance of which can scarcely be overestimated.

CONCESSION FOR PAPER MAKING IN TURKEY.

The following information respecting industrial monopolies recently granted in Turkey is extracted from a report by Mr. W. H. Wrench, Her Majesty's Consul at Constantinople:—

"During the year 1885—86, six concessions for the establishment of factories in Turkey have been granted by the Ottoman Government, among which the following one is of interest:—

"A monopoly for the manufacture of paper, granted to a high palace official. Besides the privileges conceded to the foregoing monopolies, this concession enjoys a term of monopoly for 50 years for the whole empire, and the factory may be established in any part of Turkey the concessionary may select. If the site chosen should belong to the State it will be granted free and without purchase. At the expiration of the 50 years the concessionary is bound to give up the factory to the Ottoman Government, who will purchase the machinery, etc., but take over the building. The refusal for the future working of the affair will then be offered to the concessionary or his heirs.

"This concession is now in the market, and negotiations are being carried on with certain Austrian financial houses."

MISCELLANEOUS TRADE NOTICES.

THE NEW GERMAN SUGAR LAW.

On page 190 of the *Board of Trade Journal* for August will be found a dispatch from Mr. C. S. Scott, Her Majesty's Charge d'Affaires at Berlin, enclosing copies of the text of the new sugar law which was published in the *Official Gazette* on the 15th July, and of a memorandum thereon.

PRODUCTION AND EXPORTS OF CHILIAN NITRATE.

The following information respecting the production of Chilian nitrate during the month of April last, and the exports for the four months ended the 30th April, is extracted from the *Chilian Times* for the 21st May:—

"The total exportation of nitrate from all the nitrate ports in April was 968,654 Spanish quintals as compared with 712,266 quintals in the corresponding month of last year.

"The total loadings of nitrate at all the nitrate ports on April 30th amounted to 815,440 Spanish quintals, as compared with 806,304 quintals on the corresponding date of last year.

"The total production of nitrate in the province of Tarapacá in April was 512,237 metric quintals; the quantity sent down to the shipping ports was 438,080 metric quintals; and the stocks on hand at the works on the 30th April amounted to 456,346 metric quintals.

"The exports of nitrate to the United Kingdom directly amounted to 105,771 Spanish quintals for the first four months of 1887, as compared with 21,831 quintals for a corresponding period in 1886; the exports to the United Kingdom or to the Continent for orders amounted to 1,505,508 quintals in 1887, as compared with 1,346,667 quintals in 1886; the exports to Hamburg and Bremen 576,669 quintals in 1887, as compared with 205,282 quintals in 1886; those to the United States, east coast, reached 663,209 quintals in 1887, as against 422,137 quintals in 1886. The total amount exported during the first four months of 1887 was 3,311,742 Spanish quintals, as compared with 2,180,988 for the corresponding period of 1886.

THE POSITION OF THE CHEMICAL INDUSTRY IN CHILI.

The chemical products of Chili are as follow:—Sodium nitrate, iodine, copper, silver, gold, mineral acids, beer, alcohol, brandy, wine, matches and sugar. The nitre and iodine industries are very important, and both form the most important articles of the Chili export trade. The mining industry is considerable, as regards the production of copper and silver. The works are not managed by chemists, but rule of thumb assayers—ensayadores—make the necessary tests without having any notion of the chemical reactions. These ensayadores have a low social position, and are very badly paid. At Quilpué, near Valparaiso, there is a small works making sulphuric, hydrochloric and nitric acids, owned by an Englishman and managed by a German chemist. There are match works at Santiago and Rancqua. At Vina del Mar there is a large sugar refinery owned by a German and managed by a German chemist. Another similar works, which owes its origin to German enterprise, is in course of erection. All these establishments buy their engines and machines from England and Germany. At Valparaiso there are several engine shops and foundries, but it is cheaper to get engines from Europe. The mining industry is partly in the hands of Chilian and partly English capitalists. The mining engineers are chiefly natives, who received their training in Germany. Laws, taxes and fiscal conditions are very favourable to the establishment of chemical works, and the Chilian Government promotes the development of any industry. Foreigners enjoy the same rights as natives. However, the consumption of chemical products is still very small both in Chili, Peru and Bolivia.—*Chem. Zeit.* xi. 815.

CONSULAR REPORTS.

BRAZIL.

Chemical Imports.

During the financial year 1885—86 the imports of chemical and pharmaceutical products into the port of Ceará amounted to 23,961 reis value, of which 13,412 reis were received from the United Kingdom, the rest from the continent of Europe. The port of Pernambuco imported in 1885 £36,412 worth of chemical products, and in 1886 £40,775 worth.

BULGARIA.

Drug Imports.

English imported goods are mostly articles of the first necessity, which are not likely to be undersold by foreign importers, and include drugs and dyes. In these articles the demand has been considerably in advance of that obtaining in 1885, and still more of that of 1884. Turkish imports, though relatively greater than those of the year 1885, have in reality very much fallen off owing to the import duty of 8 per cent. *ad valorem* imposed on them since June of last year. Austria is making rapid strides, and at her present rate will soon compete with England in the value of her imports.

CHINA.

Dyestuffs.

The imports of dyestuffs into the Chinese port of Chin-Kiang increased from 244,245 bottles in 1885 to 271,139 in 1886. Foreign dyes are displacing native for dyeing silk and the finer kinds of cloth. They cost £6 a case of 250 bottles, whilst 133lb. of native can only be bought for the same sum. The foreign article can also dye a greater number of pieces than native, but the Chinese dyes stand washing better, and do not fade. Indigo is being grown in the neighbourhood of Chin-Kiang in increasing quantities, but the growers complain of the competition they have to endure from foreign bottles, reducing their profits and underselling their blue. Dealers in native dyes say, on the other hand, their business is as large as ever, but is confined more than was formerly the case to coarse foreign cloth and to native cloth; the quantity of these kinds of cloth sold increases, however, from year to year. Dyes come from Germany from Messrs. Lembke, Gipperich, Baumwaldt, and from Offenbach, the latter being the best.

FRANCE.

Corsican Industries.

At Bastia, on the island of Corsica, large works have been erected for the manufacture of tanning extract from the wood of the chestnut trees, and very excellent quality is produced, most of which finds a market in England, the total exports in 1886 being 390 tons. Sulphide of antimony is successfully worked in two small mines in the Cap Corse, owned and worked by Corsicans; their production might be much increased with more skilled management. An English company are also erecting sulphuric acid works, but the building of these has been greatly delayed through local opposition. Large quantities of mineral water (1195 tons in 1886) are annually shipped from Corsica to France.

GERMANY.

The Frankfort-o-M. Drug Trade.

The prices of nearly all pharmaceutical articles on the Frankfort-o-M. market declined without interruption till September, 1886, and the decided improvement which then set in was principally due to a more active demand. The low price of many articles procured them a sale in new districts, and a fresh impulse was also given by a conference of the manufacturers, held for the purpose of establishing a conformity in production of sale prices.

After a lapse of many years, during which the chemical industry had to struggle for sales, an improvement seems to have set in last year, most of the articles selling well, and obtaining even higher prices, as potash, prussiate of potash, borax, blue vitriol, spirits of sal-ammoniac, etc. The import of most British chemicals fell off seriously, caustic soda declining from 2621 tons in 1885 to 1645 in 1886, soda ash from 1566 to 1079 tons, soda crystals from 5538 to 894 tons, and chloride of lime from 5096 to 508 tons. On the other hand, the imports of ammonia sulphate from Great Britain rose from 25,170 tons in 1885 to 28,270 in 1886, cinchona bark from 2373 tons to 3170 tons, chromate of potash from 571 to 853 tons, and dyewoods from 2067 to 2679 tons.

The rise in the price of chlorate of potash which set in early in 1886, continued throughout the year; it appears that English manufacturers possess the power of regulating prices for this article, as well as for chloride of lime, as the rise in the latter, for which the condition of the market did not show any valid reason, was not at all objected to by German manufacturers, but, on the contrary, met with their full approval.

UNITED STATES.

The Petroleum Industry.

In 1886 there was a marked increase in the production of petroleum in the United States, but a steady decline in all the old reliable districts; a large increase in field operations, a material increase in domestic and foreign consumption, and necessarily a larger export of crude as well as refined oil than has ever been recorded in the history of the trade.

The grave feature of the American oil industry is that the yield of the old Bradford (Pennsylvania) district, long regarded as the mainstay of the industry, where the production in one day, August 31, 1881, reached 81,000 barrels, has greatly declined, and now produces only 25,000 barrels per day. The Alleghany (Pennsylvania) district, showing in 1882, 24,000 barrels per day, now yields but 5000 barrels per day. These two districts have been the chief producers, and their rapid decline causes apprehension, and seems to foreshadow a further general decrease in the production, so far as the present available sources of supply are concerned. The domestic consumption of petroleum was at least 8 per cent. greater in 1886 than it was in 1885. The exports for the year 1886 show an increase of 5 per cent. over the previous year, especially to the East Indies, India and Siam, and South America; but the shipments to China and Japan have fallen off. Holland, Norway, and Sweden have increased their consumption, while Great Britain, Germany, Denmark and Austria have taken less.

NEW OPENINGS FOR TRADE.

SPAIN.

Opening for British Goods.

Consul Wooldrige says that he would strongly advise the increased introduction of British manufactured goods into Barcelona, and adds that he can almost promise a sure success in the speculation, English articles being better and cheaper than native goods, if the country's wants are duly studied and considered.

Elsewhere in his report, the same Consul says that very few goods are imported from foreign countries into Barcelona that could not be so from England. New industries have lately cropped up in this busy corner of Spain, which are genuinely national, such as petroleum refineries. Large quantities of petroleum arrive from Russia, Germany, and the United Stakes; also large quantities of drugs and chemical productions come to this port, which, before the treaty, giving this country most favoured nation treatment, was signed, it was most difficult for England to compete with, as was shown by the insignificant quantities of these articles imported from here. The power of foreign competition is becoming lessened, and British success by no means depends, as before, on custom-house tariffs, enabling other foreigners to enjoy advantages denied to British traders, but on the commercial attainments possessed by British agents in opposition to German and French. The countries which at present compete with England in supplying goods to Barcelona are France, Germany, Belgium and Italy, and they compete strongly in, among other things, drugs.

Travellers must be Sent.

The British Consul at Malaga, in common with his fellows almost everywhere else, takes up the parable of the necessity for English traders to send out travellers. Something more, he says, than the mere reduction of the tariff on British goods is still apparently wanting to bring back from German, French, and Belgian competitors the trade which they were able to divert from us during the many years that British manufactures were handicapped by a differential tariff. So much has already been written on the subject of the imperative necessity of pushing our trade and commerce, by the means adopted by our foreign rivals, that it seems superogatory to insist again upon the matter, but unless our manufacturers are prepared to make some sacrifice in this direction by the employment of commercial travellers acquainted with the language of the country, and qualified to study the requirements of their customers, they can, it is feared, hardly regain the ground that has been lost in Spain. There are at Malaga a number of young German clerks who, on their return home, will be well prepared by knowledge of Spanish for employment in German firms having business with Spain, and some such system as this might doubtless advantageously be adopted at home.

High Price of English Goods.

The same Consul goes on to say that such British goods as do find their way to Malaga, although generally acknowledged to be of better quality than foreign manufactures of the same class, are usually complained of as being too expensive, and so the dealers are forced to fall back on the cheaper wares of other countries.

SWEDEN.

The Old Cry.

Our Consul at Gothenberg declares that British trade would no doubt greatly develop by commercial travellers visiting the country with samples, studying the requirements of the people, and meeting local tastes in the nature, quality, and value of the goods most in demand.

Cash Terms Favoured.

The same Consul says that the three to six months' credit in business transactions accorded to natives by European manufacturers is not recommendable. The English system of cash terms, though inconvenient to local tradesmen, is far more preferable, and may, if other facilities be afforded, cope successfully with the money concessions of France, Austria and Germany.

TURKEY.

Diminished Trade with England.

The import of petroleum into Turkey shows an increase for 1886. Consul Dickson, writing from Damascus, says that the decrease in the imports of British goods is attributable to the stocking of the market during the previous year, on account of the over-supply in England, and also to the efforts at competition of other European countries. As regards foreign competition, he goes on to say, efforts must not be neglected on the part of British manufacturing firms to promote their interests in the East, in the same way as other foreign houses. Costly and elaborately got-up circulars are sent out to Turkey by every post which arrives from England, and no opportunity is missed by Consul Dickson to bring them to the notice of native merchants and traders; but much more could be done in the interests of British trade by the periodical visits of commercial travellers.

Credit and Travellers.

The British Acting Consul General at Beyrout cautions firms at home against giving long credit. German traders are infinitely more accommodating in this respect than British, and it is due greatly to this fact that Germans hold in their hands as much of the trade as they do. But increase of trade does not always mean increase of profit, when on an unsound basis, and under these conditions it is more than doubtful whether in the end any profit will be realised. It would be impossible to do much business with Beyrout if cash payments were insisted on, but three months should be the outside limit of credit.

With regard to the question of commercial travellers, he says that it is undoubtedly a fact that whereas many German and French travellers visit Beyrout, a traveller on behalf of an English firm is a rarity. He thinks something might be done by catering for the requirements of the natives.—*Brit. and Col. Drug.*

STATISTICS.

TRADE STATISTICS FOR JULY.

The Board of Trade Returns for July show the following figures :—

Imports.

	July, 1886.		July, 1887.
Total value....	£29,452,497	....	£28,958,156

Exports.

	July, 1886.		July, 1887.
British and Irish Produce ...	£18,480,374	....	£19,181,595
Foreign and Colonial Produce (partly estimated)	6,097,107	....	5,541,601

Below are the details affecting drugs and chemicals :—

Imports.

		July 1885.	July 1886.	July 1887.
Drugs, unenumerated..	value £	58,712	46,226	54,517

MISCELLANEOUS.

RESTRICTIONS ON THE RUSSIAN TRADE IN FOREIGN MEDICAMENTS.

The Russian Government some time ago adopted most stringent measures to restrict the trade in foreign medicinal preparations in Russia, which consumes very large quantities of these articles. Recently an official order has been issued reminding the customs officials of the provisions of the new law, and ordering them to be applied with the utmost rigour. The importation and sale of foreign medicinal preparations is only permitted if the preparations do not contain any noxious ingredients, and if they can be manufactured only by the aid of expensive or not easily obtainable appliances, or if special skill is required in their manufacture (a proviso obviously intended to foster Russian industry by excluding all preparations which can be manufactured in the country itself). The articles to be imported must be in good condition. All prepared medicaments, the importation of which is permitted, must be sold in Russia at a price fixed by Russian authorities. The formula of secret medicines must be published three years after their first importation. All newspaper and other advertisements relating to medicines must be approved by the authorities previous to publication.

SOAP-MAKING IN JAVA.

At Samarang, in Java, a soap factory is now in full swing; every preparation has been made, and all the raw material for the purpose are at hand. It is well known that of all animal and vegetable fats, cocoa-nut oil is the best for manufacturing certain kinds of soap in great demand in Europe. Mr. Steenberg, who has started the Samarang enterprise, is confident that he can turn out soaps equal in every way to the imported article, at moderate but remunerative rates. If the project succeeds there is a chance that the very large market for English soaps which now exists in Java may, to some extent at least, be lost.

THE CONVENTION OF GERMAN SODA MANUFACTURERS.

The firms which belong to the above syndicate are the Deutsche Solvay-Werke in Bernburg, the Chemische Fabrik Buckau in Magdeburg, Rob. Suermont and Co. in Bontwy, the Nurnberger Sodafabrik, Engelcke and Krause Trotha, the Rothenfelder Salinen- und Soolbad-Actiengesellschaft in Rothenfelde, the Actiengesellschaft Georg Egestorff's Salzwerke in Linden, and the Chemische Fabrik Schöningen in Schoningen. The syndicate hopes to succeed sooner or later in establishing a universal German soda association in the interest of all the manufacturers. At any rate the articles of association at present adopted leave it open to the works which have not yet joined to become members when they please.

DRUGS AND CHEMICALS FOR JAPAN.

A comprehensive review of the foreign trade of Japan in 1886 has jost been published. It is dated May 28, 1887, and is signed by Sir F. R. Plunkett, British Consul at Tokyo, who states that it has been prepared by Mr. Vice-Consul Longford. The report deals with all branches of trade, but contains several paragraphs relating to the importation of drugs and chemicals. These we shall quote verbatim, though it should be first stated that the total value of Japanese imports in 1886 was £5,577,817 and of Japanese exports £7,999,659, amounts largely in excess of any previous year.

The import trade was divided as follows:—

	£
Great Britain	2,599,753
China and Hong Kong	1,456,263
East Indies and Siam	729,615
United States and Canada	687,433
Germany	474,092
France	272,635

And the export trade as follows:—

	£
United States and Canada	3,326,103
France	1,605,009
China and Hong Kong	1,513,202
Great Britain	693,430
Germany	143,119
East Indies and Siam	107,531

Referring particularly to drugs and medicines, the Consul writes as follows:—

A considerable proportion of the import was of Chinese and Indian production, but the European portion was principally divided between Great Britain and Germany, the respective imports from each being: From Great Britain, to a value of £102,203; from Germany, to a value of £27,494. As compared with the figures for the previous year, the above amounts represent an increase of nearly £42,000 in the import of English drugs and medicines and of over £10,000 in those from Germany.

As this is not already an important trade, but one which is likely to assume in the future very considerable dimensions, I have made careful inquiry into it. I was induced in some degree to do so by various paragraphs which I have seen from time to time quoted from German trade journals, in which free expression was given to hopes that in a very short time the whole trade would become a German monopoly, and that all British drugs would be completely ousted from this market.

It is satisfactory to find that little or no foundation is afforded for these hopes by the figures contained in the customs returns for 1886, two-thirds of the total increase in the trade for that year having been in British manufactures. The customs returns have, however, to be taken with some modifications, some of the drugs which, owing to their having been imported by British merchants, are included under the heading of British manufactures, having been undoubtedly of German or French origin; while others again, entered as German manufactures, because imported by German merchants, were just as undoubtedly of British origin. As instances of these discrepancies, I may quote, salicylic acid, 5096lb., value £1782; iodide of potassium, 10,658lb., value £5572; and quinine, 36,833oz., value £5927, returned as among the British imports, but a great proportion of which was certainly of German origin; and, on the other hand, 14,700lb. of bicarbonate of soda returned as German, but, like caustic soda and other heavy chemicals, almost certainly of British manufacture. Making full allowance, however, for these and some other similar slight modifications, it is more than probable that the aggregate values above given of the import from the two countries are very nearly correct, in which case British manufactures have as yet no reason to dread the realisation of German anticipations on this trade.

The list on next page contains the principal drugs, not of Oriental origin, enumerated in the customs returns, and the approximate quantities of each imported during the past two years.

The only important items in this list in which, according to the Customs returns, the German exceeded the English import in 1886 were those of salicylic acid, cinchonine, santonine, and worm-seeds, but the modifications to which allusion has been made must be remembered.

Salicylic acid is made a specialty by large companies in Germany, holding patents for its manufacture, and the trade in it is entirely a German monopoly. The manufacture of santonine is in Russian hands, factories being established in proximity to Turkestan, where the flowers and seeds are produced, but German firms have control of its sale in Europe.

Iodide of potassium is an article not subject to any patent protection, but controlled by a trade combination; Scotch, Peruvian, and Scandinavian makers of iodine having agreed among themselves to a general course of action in regard to price and production. So far as cost of raw material is concerned, manufacturers of iodide of potassium of all countries are, therefore, on an equality; but the Germans make a nicer-looking crystal than English makers, and the Japanese, being particularly alive to appearance where, as in this case, not accompanied by inferior quality, give the preference to the German, and nearly all the trade in this article goes to Germany. German quinine is cheaper, but, though up to the necessary Japanese standard, it is doubtful if it is equal either in strength or purity to the English. Other drugs in which those of Germany have a preference to English make are cinchona, cinchonine, glycerine, and worm-seeds. Tartaric acid, glycerine, and quinine are to some extent obtained from France, and bromide of potassium from the United States. England, on the other hand, supplies carbolic acid, tartaric acid, bleaching powder, phosphorus amorphous, bicarbonate of soda, caustic soda, crystal soda, and bromide of potassium —all of which are very important items in the whole trade.

—	Import in 1886.	Import in 1885.		Increase or decrease in 1886, as compared with 1885.

In order to protect the people against the consequences of the sale by native dealers of inferior and spurious drugs, an analytical laboratory, carefully organised under foreign direction, was a few years ago established by the Government. Theoretically, this laboratory exercised no control whatsoever over foreigners, who were nominally left free to import any drugs they pleased, whether of good or bad quality. As far as drugs used for medicinal purposes are concerned, foreign importers are, however, practically entirely subject to it. No Japanese dealer is permitted to sell medicinal drugs that are not strictly in accordance with the vernacular Pharmacopœia which the laboratory has issued; and they, in consequence, decline to purchase from foreign importers any that have not either already passed through the laboratory, or that are unaccompanied by a certificate from a well-known chemist, or other satisfactory guarantee that they meet all the necessary requirements.

The tests used by the laboratory generally admit of a lower standard than is recognised by the English Pharmacopœia; but they are at the same time more severe in some details. They are, without exception, observed with the very utmost strictness, no latitude whatsoever being allowed, and any drugs, however pure and good in themselves, that fail in the minutest particular to conform to them are at once rejected.

British manufacturers are generally guided only by the British Pharmacopœia, and it is with the utmost difficulty that they can be induced to alter their productions so as to bring them into conformity with Japanese requirements. The English drug trade is very vigorously pushed by one English firm—the only firm of any nationality established in Japan whose business is exclusively in this line. A great portion of the whole trade is in their hands. A member of this firm has informed me that they are, in their own interests, in many cases forced, for the reason above stated, to have recourse to German manufacturers. In one which was quoted to me, that of bismuth, which, though included under the heading of "Unenumerated Drugs" in the Customs returns, is largely imported, he stated, "We are obliged to get all ours from Germany, as all our efforts to get from English sources an article which will satisfy the Japanese laboratory have failed, English makers considering the Japanese tests too severe, whereas we are able to get the article required from our German friends. Generally speaking, we find it more practical to do business with German makers. They are more alive to the fact of competition existing, and it is easier to do business direct with the manufacturers; while with the English it is often difficult to arrange transactions, owing to mere detail, and not price or quality."

The import of drugs is only an item in the business of those German merchants in Japan who deal in them, and cannot, therefore, receive from them the same attention and thought that the English firm just referred to is able to give to it. On the other hand, Japanese medical practitioners have been almost entirely educated by German professors, and, actuated by the spirit to which allusion has been made in another part of this report, no doubt, therefore, wherever possible, give a preference to German pharmaceutical preparations.

It is not, however, from an increase of the import of drugs of the latter class that an extension of this trade is to be expected in the future. The general adoption throughout the country of the European in preference to the old Chinese system of medicine, and the great increase that is yearly taking place in the number of skilled native practitioners trained under foreign professors, no doubt is creating a demand for European medicines; but there is no branch of Western science in which the Japanese have attained greater proficiency than that of chemistry, and they can already, and are yearly becoming more and more able to make themselves all extracts, tinctures, and other preparations prescribed by the Pharmacopœia. This trade will, therefore, always be a restricted one, even if it does not in time come to an end altogether, or if, as is not impossible, the Japanese do not become exporters rather than importers. But in all heavy chemicals, alkalis, and such as are required in manufacturing industries, the import is not only yearly increasing, but it promises to continue a progressive one, and to grow ultimately to very large dimensions. It is this class of goods which really interests British manufacturers most, and in it they need fear no competition to any serious extent, if they will only adapt themselves to the requirements of the Japanese market, rather than expect the latter to adapt itself to them.—*Chem. and Drug.*

Monthly Patent List.

I.—GENERAL PLANT, APPARATUS AND MACHINERY.

APPLICATIONS.

10128 H. Appleby, London. Improvements in and connected with blast pipes. July 19

10166 J. Imray—From A. Moszczensky, Russia. Manufacture of refractory crucibles, pots, bricks, and lumps for furnaces. July 20

10203 H. C. Bull & Co., Lim., and H. C. Bull, London. An improved calcining oven. July 21

10205 H. C. Bull & Co., Lim., and H. C. Bull. Improvements in or connected with gas producers. July 21

10216 G. Downing—From F. Morin, L. van Effenterre, and P. Thiercelin, France. Method of and means and appliances for regulating the pressure of liquids and gases. July 21

10269 J. A. Breysse, London. Insulating pipes, etc., for the retention or exclusion of heat, and for like purposes. July 22

10301 W. Heidenhain and H. Hoffmann, Berlin. Platine presses. Complete specification. July 23

10393 F. W. Tucker, London. Hot-air bridge walls for furnaces. Complete specification. July 26

10401 J. Shone and E. Ault, Liverpool. Apparatus for raising and forcing liquids. July 26

10402 A. J. Boult—From W. C. Shaffer, United States. Application of the expansive power of heat, and apparatus therefor. Complete specification. July 26

10512 J. Stewart and T. Charlton, London. Method and means for storing volatile or inflammable liquids. July 28

10513 J. Stewart and T. Charlton. Method and vessels for storing and transporting volatile or inflammable liquids. July 28

10535 H. Davey, Westminster. Air-compressing pumps. Complete specification. July 29

10595 J. J. Hicks, London. Anemometers and pressure and vacuum gauges. July 30

10723 R. Cunliffe and J. Lund, London. Apparatus for calcining, drying, roasting or carbonising substances or materials and extracting gases, spirits or acids therefrom. Complete specification. August 1

10735 H. A. Snow, London. Means for connecting pipes and cocks to vessels of earthenware, stoneware, glass and other similar materials. August 4

10758 N. Clayden—From D. Francis, South Africa. An improved amalgamator. August 5

10862 W. H. Symons, London. Construction of cocks and valves. August 8

10957 L. Mond, London. Apparatus for treating solids by gases, also applicable to other purposes. August 10

10976 J. B. Hannay, Glasgow. Furnaces or heating apparatus. August 11

10991 J. H. Plant, Liverpool. Improvements in heads and lids of caustic drums, and for like purposes. August 11

11022 T. Nixon, Sheffield. An improved valve for water, steam or other fluids, and especially suitable for acids. August 12

11035 R. Clayton, London. Construction of filters. Complete specification. August 12

11050 G. E. Stead and T. W. Duffy, Leeds. Means or method for purifying water; applicable also for preventing incrustation in boilers. August 12

11139 R. Johnson, Bradford. Air compressors. Complete specification. August 15

11154 R. Howarth, London. Machines for drying granular, fibrous and like materials; also applicable for cleaning, bleaching, damping, germinating and disinfecting. August 16

11127 J. P. Jackson, Liverpool. Filters August 17

11292 J. S. Croft and G. T. Appleyard, London. Refrigerators. August 18

11310 E. Edwards—From E. M. Heiber, Germany. Improved boilers, and apparatus for preventing and removing deposit or incrustation therein. August 18

COMPLETE SPECIFICATIONS ACCEPTED.[*]

1886.

10037 E. Edwards—From G. Lunge and L. Rohrmann. Apparatus for effecting the absorption of gases by liquids or solids. July 30

11959 C. G. P. de Laval. Apparatus for supporting and working centrifugal machines. July 23

12018 A. M. Clark—From V. A. Pilloud. Apparatus for automatically compressing air. July 23

12061 H. R. Lipscombe. Composition for softening and purifying water. August 17

12352 J. L. Wade. Composition for preventing incrustation. July 30

12395 T. Hill. Apparatus for heating, cooling and condensing. August 10

12418 G. Best. Apparatus for condensing steam. August 13

12769 W. Burns. See Class III.

12975 F. H. Stacey and H. Wilkinson. Apparatus for blowing, exhausting and pumping. August 6

13799 W. G. Gard. Liquid for preventing and removing incrustation in steam boilers. August 3

14933 A. Cockey and W. Smith. Self-acting safety bye-pass gas valves for gas exhausters. July 23

16290 J. B. Hannay. Apparatus for condensing, absorbing or washing gases or fumes, etc. August 17

1887.

7723 O. Kruschki. Heating apparatus with air supply from above. July 30

7814 E. Palmer. Bricks and fire bridges for furnaces, etc. July 30.

9015 H. H. Lake—From A. P. Ligbthill. Atomisers. July 27

9047 O. Brunler and C. G. Rommenhöller. Pressure reducing valves for highly compressed gases, and especially for carbonic acid. August 6

9110 P. A. Newton—From R. A. Chesebrough. Hot air furnaces. August 3

9165 G. Blackwell. Rotary exhausters or pumps for gas and other fluids. August 6

II.—FUEL, GAS AND LIGHT.

APPLICATIONS.

10112 R. Haddan—From T. T. Prosser and H. Waller, jun., United States. Process for utilising products of heat. Complete specification. July 19

10127 J. J. Hood and A. G. Salamon, London. Improvements in the desulphurisation of gaseous and other products. July 19

10371 E. F. Gwynne, London. Improved combination of ingredients for lighting fires. July 25

10558 O. E. Guibout, Liverpool. Improvements in and relating to apparatus for lighting and heating by means of gas. July 29

10603 T. Fletcher and A. Clare, Manchester. Improvements in incandescent gas fires. July 30

10628 A. D. Mackenzie and G. G. Moncur, Glasgow. Improvements in radiators for heating purposes August 2

10686 T. H. Gray, Norwood. Improvements in the treatment of hydrocarbon illuminating oils. August 3

10684 E. Grahn, Liverpool. An improved process for treating gas liquor and other ammoniacal liquors. August 3

10743 J. H. W. Stringfellow and W. Brown, London. Improvements in carburetting or enriching gas or air, and apparatus therefor. August 1

10861 R. H. Michell, Wiesbaden. Consuming smoke, and thereby economising fuel. August 8

11119 J. Castle, E. Castle, and E. Braithwaite, London. A new or improved arrangement of reflectors for distributing, concentrating, increasing and shading artificial light. August 15

11195 O. Imray—From C. A. von Welsbach, Austria. Improvements in incandescence bodies for illuminating purposes, and in the treatment of mantles produced therefrom. August 16

11201 J. Tennent, Liverpool. Improvements in or appertaining to the transmission of heat from one fluid body to another. Complete specification. August 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10861 T. P. Hollick. Apparatus for raising the covers of gas-purifiers and other weights. August 17

11833 J. M. Turnbull. Manufacture of gas from mineral oil, and apparatus therefor. August 10

12769 W. Burns. See Class III

14111 G. Sengrave—From P. Fougeron, jun. Construction and arrangement of carburetting apparatus. August 3.

14958 W. Burns. Distillation of tar, oil, resin and liquid hydrocarbons; the manufacture of illuminating and heating gases therefrom, and apparatus for that purpose. July 30.

1887.

7518 J. Belou. Process for manufacturing pure hydrogen. July 30

9391 C. S. Ellery and J. Chaflin. Preventing the choking of pipes between the retort and hydraulic main in gas-works. August 3

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

12769 W. Burns. Construction of retorts and apparatus for the destructive and cummulative distillation, carbonising and calcining of dry compound substances. August 6

14958 W. Burns. Distillation of tar, oil, resin and liquid hydrocarbons in the manufacture of heating and illuminating gases therefrom, and apparatus therefor. July 30

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

10223 S. Hallsworth and R. Bailes, London. Improvements in the manufacture or preparation of a certain material to be used for dyeing purposes. July 21

10554 J. A. Walton, London. A liquid blue. July 29.

11318 H. H. Lake—From Leonhardt & Co., Germany. Improvements in the manufacture of alpha-naphtholdisulpho acid, and in the production of colouring matters therefrom. August 18

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

12054 R. Ripley. Forming blacklead, blue and other like substances into packets.

12908 G. Pitt—From L. Cassella & Co. Manufacture of new naphtylaminemonosulphonic acids and of dyestuffs therefrom. August 10

13166 C. A. Bennert. Manufacture of Colouring compounds or materials. August 20

13473 C. A. Bennert. Treatment of certain colouring compounds to render them soluble, or more soluble, and suitable for dyeing and printing. August 20

1887.

10046 C. A. Bennert. Manufacture or production of colouring matters. August 20

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

10137 T. F. Wiley, Bradford. A new or improved process of, and apparatus for, waterproofing textile fabrics. July 20

10650 P. Cohnreich, London. Improvements in oiling or fatting wool, and apparatus therefor. August 2

10979 W. Marriott, Huddersfield. A new process and means for separating silk, cotton, or vegetable matter from wool. August 11

11182 W. J. Grawitz, London. Process for the treatment of textile materials dyed with aniline black. August 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10035 A. Wilkinson. Treatment of plants, shrubs, barks and other fibres to be used in spinning processes, and to be woven into textile fabrics. August 6

13054 T. Honeywood. Preparation of fibre for textile and other purposes. August 17

1887.

6461 C. C. Kauffmann. Process and apparatus for treating ramie, jute and other fibres. July 23

8575 H. H. Lake—From C. Shrebler. Drying and carbonising wool, and apparatus therefor. August 17

---

[*] The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

VI.—DYEING, CALICO PRINTING, PAPER STAINING AND BLEACHING.

APPLICATIONS.

10113 A. Gilliard, P. Monnet, and J. M. Cartier, London. Improvements in the production upon fibres and fabrics of colours varying from black or brown-black to blue-black and blue. July 9

10591 J. Robertshaw, London. Improvements in machines employed in dyeing, sizing washing, and wringing hanks. July 30.

10679 C. F. Young, Manchester. Improvements in the treatment or method of using certain dyes or combinations of dyes. August 3

11154 R. Howarth. See Class I.

11219 E. Sutcliffe and G. E. Sutcliffe, Manchester. Improvements in the production of grey and coloured cotton yarns. August 17

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

13,362 F. A. Gatty. Dyeing cotton, cotton yarns and cotton fabrics. August 17

1887.

9720 C. Meadowcroft and P. Denanhouer. Apparatus for dyeing skeins. August 13

9722 W. P. Thompson—From J. Meikle. Apparatus for cleaning and bleaching cotton and other fibrous and textile fabrics. August 13

VII.—ACIDS, ALKALIS AND SALTS.

APPLICATIONS.

10093 C. J. Bayer, London. Process or processes and apparatus for obtaining pure alumina compounds from bauxite and similar materials containing alumina. July 19

10141 S. Hallsworth and R. Bailes, Leeds. Improvements in or relating to the manufacture of copperas, and of ferric sulphate or sesqui-persulphate of iron, commonly called nitrate of iron. July 20

10153 J. Fleming, Glasgow. Improvements in connection with the calcining of sulphurous ores. July 20

10154 J. Fleming, Glasgow. Improvements in the construction of chambers or towers wherein acids are generated, or through which they are passed, the said improvements being applicable to the construction of condensers or tanks used in the manufacture of acids. July 20

10168 W. H. Knowles—From — Phol, United States. Improved apparatus for generating carbonic acid gas for forcing or raising beer and other liquids, and for other purposes. July 20

10222 S. Hallsworth and R. Bailes, London. Improvements in or relating to the manufacture of ferric sulphate, or sesqui-sulphate of iron, commonly called nitrate of iron. July 21

10295 C. Wigg, Liverpool. Improvements in obtaining ammonia and carbonic acid from the residual chloride liquors of the ammonia alkali process. July 23

10305 E. H. Hutchinson, London. Improvements in compressing sea-salt and chemicals having the same properties, and apparatus therefor. July 23

10307 P. Bateson and M. C. Arnoltz, Liverpool. Improvements in apparatus for the manufacture of bicarbonate and carbonate of soda by the ammonia soda process. July 23

10329 T. Bayley, Birmingham. Improvements in the treatment of waste acids. July 25

10346 J. F. Peasgood, Streatham. A specially pure and acid vinegar. July 25

10585 S. Wolf, Liverpool. Improvements in or connected with the application or utilisation of acid sulphate of soda in the manufacture of cellulose, and for other purposes. July 30

10610 T. O. Nesbit and T. Forster. See Class XII.

10759 H. W. Deacon—From C. Arnois, United States. Improvements in the manufacture of carbonic acid gas. Aug. 5

10818 J. Hanson, London. The utilisation of alkali waste for the manufacture of sulphuric acid. August 6

10900 J. B. Thompson, London. Improvements in the manufacture of soda, and in apparatus therefor. August 9

10955 L. Mond, London. Improvements in obtaining ammonia, chlorine and hydrochloric acid from ammonium chloride, and in apparatus therefor. August 10

10957 L. Mond, London. See Class I.

10966 T. Schloesing, London. Improvements in the treatment of hydrochlorate of ammonia resulting from the manufacture of carbonate of soda, with a view to the extraction of chlorine. August 10

10991 J. H. Plant, Liverpool. See Class I.

11022 T. Nixon. See Class I.

11156 T. S. Mathieson and J. Hawliczek, Liverpool. Improvements in the manufacture of caustic soda and caustic potash from their respective sulphates, the recovery of certain by-products therefrom, and apparatus employed therein. August 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10298 F. Maxwell Lyte. See Class XII.

11891 A. Brin and L. Q. Brin. Manufacture of bleaching liquid. July 23

12070 A. Brin and L. Q. Brin. Treatment of copper and iron pyrites for the manufacture of sulphuric acid and oxides of copper and iron; and treatment of the said oxides for the production therefrom of metallic copper and the higher oxides of iron. August 3

12110 J. J. Hood and A. G. Salamon. Manufacture and purification of metastannic acid. July 23

12769 W. Burns. See Class III.

13001 J. I. Watts and W. A. Richards. A new sodium product and method of manufacturing same. August 10

16290 J. B. Hannay. Apparatus for condensing, absorbing or washing gases or fumes. August 17

1887.

9047 O. Brunler and C. G. Rommenholler. See Class I.

9048 O. Brunler and C. G. Rommenholler. Apparatus for using liquid carbonic acid in large quantities. August 13

9188 E. Banisch and M. Schroder. Process and apparatus for production of sulphuric anhydride. August 6

VIII.—GLASS, POTTERY AND EARTHENWARE.

APPLICATIONS.

10085 C. Toft, Newcastle-under-Lyme. The ornamenting and decorating of pottery and porcelain by an imitation of lead or metal mountings used for stained glass. July 19

10156 R. W. Willis and A. J. Willis, London. Improvement in enamelled letters and figures for fixing to glass and other polished surfaces. July 20

10258 J. B. Payne and R. Davison, London. A new or improved portable or fixed gas kiln for burning and staining glass, china, enamels, tiles and ceramic wares, also applicable to other purposes. July 22

10556 T. Buck, junr., London. Improvements in brick and tile making machines. July 29.

10735 H. A. Snow, London. See Class I.

10762 W. Lewis, Halifax. Improvements in the arrangement and construction of fire-clay, terra-cotta or fire-brick domestic fire-places. August 5

10812 J. Earle, G. Bourne, and T. Bourne, London. Improved apparatus for cutting and ornamenting glass. Complete specification. August 6

10811 H. J. Shawcross. See Class XIX.

10858 J. Gill, London. Improvements in machinery or apparatus for the manufacture of pottery, pressing bricks, and the like. August 8

10874 A. J. Boult—From P. Sievert, Germany. Improvements in glass furnaces. Complete specification. August 8

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

11870 R. Kelsall and W. Lee. Machinery for drying pottery ware. July 30

12793 H. L. Doulton and W. P. Rix. Production of ornamental pottery ware. August 20.

13209 W. Lutwyche—From A. Ceresa. Producing mosaics by means of enamel substances and coloured glass. August 20.

1887.

7516 H. Godwin and W. Hewitt. Making and connecting tile or ceramic fenders and ceramic mouldings generally on new and improved principles. August 10

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

APPLICATIONS.

10236 C. A. F. Gregson, London. Improved means or appliances for use in the erection of walls of concrete or like material. Complete specification. July 21

10244 J. S. Rigby, Liverpool. Improvements in the manufacture of cement. July 22

10324 W. Matthews, London. Improvements in the manufacture of Portland cement. July 23

10377 W. Youlten, London. Improvements in fireproof floor construction. July 26

10385 E. Larsen, London. Improvements in the manufacture of slag cement and in the preparation of raw materials used therefor. July 26

10446 C. J. Howe, London. Improvements in the manufacture of plaster of Paris. July 27

10530 J. W. H. James and F. Ransome, Liverpool. Improvements in and connected with furnaces for burning hydraulic lime, cement and like substances. July 29

10764 F. W. S. Stokes, London. Improvements in the methods and apparatus for drying cement slurry, and the subsequent cooling of the burnt cement. August 5

10779 **E. de Pass**—From **J. M.** Danielli, France. A method or process for imitating, by casting, white and coloured marble. August 5

13898 **E.** Keirby, London. A new or improved compound or cement, and application of the same in making asphalte walks, in renovating and repairing old asphalte walks, in coating and protecting masonry, and for other analogous purposes. Complete specification. August 9

11274 J. S. Rigby, Liverpool. Improvements in the treatment of lime mud and like substances, to obtain whiting and cement, and in apparatus therefor. August 18

COMPLETE SPECIFICATION ACCEPTED.

1887.

857 A. C. Ranyard. Paving road and other ways. August 3.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

10152 J. Fleming, Glasgow. Improvements in treating copper matte. July 20

10153 J. Fleming. See Class VII.

10189 R. Bentham, Atherton. Miners' portable electric lamp. July 21

10206 H. C. Bull & Co., Limited, and H. C. Bull, London. An improved metallurgical process, and apparatus therefor. July 21

10266 J. Wilkes and E. Mapplebeck, London. Improvement in cores used in casting tubes of copper, brass and other metals and alloys. July 22

10276 C. Netts, London. Improvements relating to the preparation of sodium and potassium. July 22

10338 J. Routledge, Sunderland. The safe blasting of shots with a safety blasting cartridge. July 25

10387 J. W. Wailes, Liverpool. Improvements in and applicable to open hearth steel-melting and like furnaces. July 26

10400 W. J. Wilder, Liverpool. Improvements in process of coating metals. Complete specification. July 26

10406 H. J. Allison—From B. Atha and W. R. Hinsdale, United States. Process and apparatus for forming metallic ingots in a sectional bar. July 26

10443 C. P. Tabary, London. A new description of metallic cement and processes for its manufacture. July 27

10538 C. E. Miles, London. Improvements in furnaces for smelting ores. July 29

10552 H. Johnson, London. Improvements in hand punches for making bore holes for blasting and wedging operations in getting coal and other minerals, and for like purposes. July 29

10561 A. Neujean, London. Improved method of utilising and applying basic slag alone or in combination with other materials to various useful purposes. July 29

10570 A. E. Carroll and W. P. Burnley, Manchester. Improvements in compositions for use in the preparation of the moulds for steel and other metal castings. July 30

10588 F. Fenton, Batley—From J. Woolford, France. Improvements in extracting gold from simple, compound and refractory ores, or slags, or wastes, or cinders of ores or metals containing gold or gold blends. July 30

10594 C. T. J. Vautin, London. An improved method of extracting gold from the various auriferous ores. July 30

10614 L. Mellett, London. Improvements in means or apparatus for use in ascertaining and indicating the presence of mineral ores or metallic substances. Complete specification. August 2

10622 J. Gill, London. Improvements in apparatus for the manufacture of sleeves of refractory material for the stopper-bars of vessels containing molten metal. August 2

10659 W. P. Thompson—From G. L. Kobert, France. Improvements in converters. August 2

10738 A. W. Daw and Z. W. Daw, London. Improvements in rock drills. Complete specification. August 4

10815 W. P. Thompson—From M. G. Farmer, United States. New and improved process and apparatus for procuring aluminium. Complete specification. August 6

10817 J. Y. Johnson—From La Compagnie Anonyme des Forges de Châtillon et Commentry, France. Improved means and apparatus for tempering armour-plates and other massive articles of iron or steel. August 6

10820 T. Mallinson, London. Improvements in apparatus for use in the manufacture of tinned wire. August 6

10868 J. Toussaint, London. An improvement in the construction of furnaces for refining iron, steel or other metals. August 8

10893 M. H. Smith, Halifax. Improvements in apparatus for separating iron from other substances. August 9

10918 F. W. Dahne, London. Improvements in refining copper, copper regulus and copper precipitate, and more especially such copper products as contain arsenic and other volatile impurities. August 9

10922 C. Roth, London. Safety apparatus to be employed for igniting fuses especially adapted for use in blasting operations in coal mines for preventing explosion of fire-damp. Complete specification. August 9

10951 J. H. Lamprey, London. An improved armour for ships, floating structures, fortifications, targets, and the like. August 11

11025 J. Coombs, London. Improvements in ore separators or gold extracting machinery. August 12

11128 J. Foster and J. S. Caldwell, Liverpool. Improvements in miners' or safety lamps. August 15

11142 H. H. Lake—From B. Atha, United States. Improvements relating to the casting of metal ingots or bars, and to apparatus therefor. August 15

11210 H. H. Lake—From S. Heilbronn, Germany. Improvements in apparatus for boring or drilling earth, rock, or the like. August 16

11233 J. Hollnay, London. An electro deposition of metal. August 17

11267 W. Priestland, Chesterfield. An improved core barrel for making cast-iron pipes. August 18

11268 G. A. Jarvis, Wellington, Salop. The manufacture of sodium and potassium. August 18

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

11972 B. H. Thwaite. Purification of iron ore and fluid iron metal, and apparatus therefor. July 30.

12070 A. Brin and L. Q. Brin. See Class VII.

12128 R. Poole. Box and cover, for use in annealing sheet iron, etc. July 27.

12601 J. D. Ellis. Manufacture of iron or steel plates with ribs or projections, and apparatus therefor. August 6.

12692 H. W. Bessemer. Manufacture of malleable iron and steel, and apparatus therefor. August 6.

12866 J. Gilchrist and D. Ballardie. Miners' lamps. August 13.

13238 J. Havenhand. Ingot moulds. August 10.

13239 G. H. Lloyd, A. L. Lloyd and H. Bewlay. Manufacture of pipes of malleable metal. August 17.

13460 R. Heathfield. Apparatus for coating sheets and articles of iron and steel with zinc or alloys of zinc and other metal. August 10.

1887.

2780 J. Dahl. Annealing steel. July 30.

3531 T. Shaw. Method and apparatus for testing gases drawn from mines, and signalling results. July 27.

6370 S. T. Montagne. Process and apparatus for recovering tin from tinned cuttings and scrap. July 27.

7519 J. Belou. Treatment of ores. July 30.

7533 F. J. Clamer and J. G. Hendrickson. Process for cleaning, preparing and coating metal plates and surfaces. July 23.

8599 E. Walsh, jun. Method and apparatus for reducing zinc ores and collecting metallic zinc therefrom. July 30.

8712 J. Y. Johnson—From A. de Meritens. Process for browning or colouring iron or steel surfaces and protecting them from rust. July 27.

9499 A. J. Boult—From W. H. Larimer. Drills for mining purposes. August 20.

XI.—FATS, OILS and SOAP MANUFACTURE.

APPLICATIONS.

11021 G. Gourley, Glasgow—From T. Bell, Auckland. An improved lubricating oil, and the method of manufacturing the same. August 12

11115 W. P. Kelly, London. A new composition to be used as a lubricant. August 15

XII.—PAINTS, VARNISHES and RESINS.

APPLICATIONS.

10610 T. O. Nesbit and T. Forster, Newcastle-on-Tyne. An improved method of producing white lead and other compounds and combinations of lead. August 2

10656 A. J. Boult—From T. Rosenfeld, J. Zeleny and A. Weiss, Austria. An improved manufacture of paste for protecting metal alloys against rust. Complete specification. August 2

11068 J. J. Speakman, London. Improved compositions for use as "paint restorers," or paint or varnish removers, and for cleaning various surfaces. August 13

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10298 F. M. Lyte. Manufacture of white pigment. August 3.

13416 J. B. Hannay. Manufacture and treatment of lead pigments and compounds, and apparatus therefor. August 17.

13799 W. G. Gard. See Class I.

XIII.—TANNING, LEATHER, GLUE and SIZE.

APPLICATION.

11253 T. Palmer, London. Improvements in tanning, and in tanning apparatus. August 17

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

11005 C. Wagner, jun. Machines for skiving or sharpening leather. August 17.

12681 E. P. Nesbit. Process for clearing hides, skins, hair, wool, or fur from lime. August 6.

13636 T. Palmer. Purifying and graining or bating hides and skins, and apparatus therefor. August 20.

XIV.—AGRICULTURE, MANURES, Etc.

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

12772 W. S. Squire. Obtaining manure from distillers' spent wash. August 10.

1887.

10060 T. Roxburgh. Process of making manure. August 29.

XV.—SUGAR, GUMS, STARCHES, Etc.

APPLICATIONS.

10158 J. T. Griffin—From R. J. Henderson, United States. The manufacture of soft or spongy material from rubber compound. Complete specification. July 27

10523 R. T. Lloyd, London. Improvements in and connected with syrup pumps. July 28

10812 L. E. A. Prangey, London. Improvements in the manufacture of sugar, and in the apparatus to be employed therefor. August 8

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

11048 F. Candy. Materials for use in purifying and decolourising liquids and solutions. August 3.

13168 E. M. Knight and A. H. Hobson. Manufacture of liquid cement or gum. August 17.

1887.

9751 E. J. P. Robet. Treating vegetable milky juices, and extracting therefrom indiarubber, gutta-percha, mangabeira, etc. August 13.

XVI.—BREWING, WINES AND SPIRITS.

APPLICATIONS.

10108 W. Wild, London. Improvements in or applicable to the manufacture of grape wines. Complete specification. July 19

11227 J. P. Jackson, Liverpool. Improvements in filters for wine and other liquids. August 17

11232 R. Ranger, London. Improved apparatus for regulating the surface-flow of wort from coolers used in the manufacture of beer.

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

12772 W. S. Squire. See Class XIV.

13259 G. Thornley and T. Buxton. Apparatus for expelling liquid from spent hops. August 20

1887.

9015 O. Brünler and C. G. Rommenholler. Means for impregnating beer and other liquids with carbonic acid in the cask. July 27

9016 O. Brünler and C. G. Rommenhöller. Process and apparatus for automatically mixing liquids with carbonic acid. July 27

9019 O. Brünler and C. G. Rommenhöller. Process and apparatus for the automatic mixing of liquids with carbonic acid. July 27

10018 W. Wild. Manufacture of grape wines. August 20

XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, Etc.

APPLICATIONS.

A.—Chemistry of Foods.

10117 A. Brin and L. Q. Brin, Westminster. Improvements in means and apparatus for producing pure oxygenated drinking waters. July 27

10647 J. Lyle, London. Smoke-curing fish, flesh and other food, and the application of tar and other substances for the purpose. August 2

10810 H. R. Romney, London. An improved process for desiccating cocoa-nut and other materials. August 6

10915 H. H. Lake—From H. C. Andrews, United States. Improvements in apparatus for drying or curing fruit, tobacco, and other substances. Complete specification. Aug. 9

10917 H. H. Lake—From T. C. Oakman, United States. Improvements in apparatus for drying or curing fruit, tobacco and other substances. Complete specification. Aug. 9

10918 W. F. Reid, London. A new or improved method or process for the preservation of fruit. August 10

10991 A. Dunderdale, Liverpool. Improvements in extracting the black colouring matter from pepper-corns, and obtaining light coloured pepper-corns thereby. August 11

11031 G. W. Charter, London. Improvements in manufacturing and preserving whole-meal, wheat and other crushed cereals used for bread, and preventing fermentation. Aug. 12

11051 G. F. Redfern—From A. Mosser and L. Chiari, France. Improvements in apparatus for preserving alimentary and other like substances. August 12

11311 G. Grout, Hornsey. An improved preparation of cocoa. August 18

B.—Sanitary Chemistry.

10901 A. H. Curling and J. Dunbar, London. Improvements in the deodorisation and disposal of sewage, and in apparatus therefor. August 9

10912 H. C. Bull and Co., Lim., and H. Clay Bull, London. Improvements in and connected with the treatment of sewage. August 10

C.—Disinfectants.

10306 E. H. Hutchinson, London. An improved method of compressing solid and liquid disinfectants, and apparatus therefor. July 23

10309 J. Hanson, London. Improvements in apparatus to be used in the generation of gases for disinfecting or deodorising. July 23

10747 A. Boake and F. G. A. Roberts, London. Improved means and apparatus for disinfecting and deodorising. Aug. 4

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1887.

1171 C. Kranz. A preparation for use as a food and condiment. July 30.

8962 F. Sievers and R. Damm. Manufacture of sausages from fish. August 10

B.—Sanitary Chemistry.

1886.

8999 W. Horsfall. Furnace for burning towns' or other refuse. August 6

12218 T. Ogden. Furnaces for desiccation, deodorisation and combustion of refuse. August 13

12382 W. B. Hallett. Preparation of materials for use in treatment of sewage, method of treatment, and apparatus therefor. August 10

XVIII.—ELECTRO-CHEMISTRY.

APPLICATIONS.

10177 E. L. Mayer and H. Leipmann, London. Improvements in the manufacture or treatment of porous pots, plates or partitions for electric batteries.

10201 H. C. Bull & Co., Limited, and H. C. Bull, London. Improvements in electric storage batteries. July 21

10217 J. Serson and J. Orville Whitten, London. Improvements in galvanic batteries. Complete specification. July 21

10322 C. Gassner, junr., London. Improvements in carbon manganese electrodes. July 23

10474 E. De Pass—From Cuénod, Sautter, et Cie., Switzerland. An improved dynamo-electric machine. July 28

10514 V. J. J. Hirbec, London. An apparatus for storing electricity and facilitating the utilisation thereof. July 28

10565 C. P. Elieson, London. Improvements in electrical batteries. July 29

10606 L. Gerard, London. Improvements relating to the distribution, storage, and regulation of electric currents. July 30

10611 R. P. Milburn, Newcastle-on-Tyne. Improvements in electrical batteries. August 2

10767 W. Lowrie, C. J. Hall, and H. W. Kolle, London. Improvements in instruments for measuring electric currents, and for regulating and controlling dynamo-electric machines and prime movers. August 5

10834 A. R. Upward and C. W. Pridham, London. Improvements in galvanic batteries. August 6

10919 E. Jones, London. Improvements in the construction of plates for secondary batteries. August 9

10952 L. Anspach and L. Gerard, London. Improvements in or connected with dynamo-electric machines and electromotors. August 10

11188 H. H. Lake—From W. E. Case, United States. Improvements relating to the conversion of chemical energy into electrical energy, and to apparatus therefor. Complete specification. August 16

11189 H. H. Lake—From W. E. Case, United States. Improvements in apparatus for the conversion of heat into electrical energy. Complete specification. August 16

11213 T. J. Digby, London. Improvements in electric accumulators or secondary batteries. August 17

11252 H. Mower, London. Improvements in secondary batteries or electrical accumulators. August 17

11315 H. H. Lake—From G. E. Cabanellas, France. Improvements in and relating to dynamo-electric machines. August 18

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

8693 W. J. Starkey-Barber-Starkey. Secondary batteries. August 6

11101 T. J. Jones and W. H. Tasker. Secondary batteries. August 3

11239 H. Carter. Electric battery, with means for regulating the amount of submersion or withdrawal of the positive plates. July 27

11242 D. E. Fitzgerald. Means for effecting the electro-chemical generation of chlorine in metallurgical operations for the extraction of gold from its ores, and for other purposes. July 23

12117 W. Maxwell. An electric furnace. July 27

12595 E. Andreoli. Secondary batteries. August 6

1887.

1648 C. L. Tweedale. Primary batteries. August 13

5720 C. Coerper. Dynamo-electric machines. August 3

9013 C. Coerper. Dynamo-electric machines. July 27

9726 W. P. Thompson—From G. Westinghouse, jun. Armatures for electric generators. August 17

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

10814 H. J. Shawcross, London. The preparation and treatment of paper, woven or tissue fabrics, glass or other material for the production of copies of drawings, designs, pictures, photographs, writings, and the like, by the action of light. August 6

11056 J. L. Lewis, London. An improvement in the manufacture of paper. August 12

11190 G. A. Wilkins—From L. H. Thomas, United States. Improvements in the manufacture of paper bottles. Complete specification. August 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

12217 R. D. Sinclair and J. G. Brown. Manufacture of paper, to render same antiseptic and germ-proof. August 10

1887.

8969 H. Gardner—From S. S. Stevens. Manufacturing pulp for paper, and apparatus for the purpose. July 27

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATION.

10260 C. Kolbe, London. Improvements in the manufacture of salicylic esters, called "Salols." July 22

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

11816 A. Brin and L. Q. Brin. Means for the manufacture or production of ozone. August 6

12610 P. H. Lecorme and Raynaud. Manufacture of perfumery. August 6

XXI.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

10518 J. Nicholas and H. H. Fanshawe, London. Improvements in the manufacture of explosives. July 28

10655 E. Turpin, London. Improvements in the production of explosives. August 2

10667 E. Turpin. Improvements in explosives. August 2.

10729 A. J. Boult—From J. S. Foley, United States. Improved match magazine and lighter. Complete specification. August 4

10821 A. Brock and G. J. Mayer, London. Improvements in the manufacture of gunpowder, and machinery or apparatus therefor. August 6

10822 A. Brock and G. J. Mayer, London. Improvements in the manufacture of quick-match and apparatus for covering the same, and other fire-work compositions. August 6

10905 H. Echberg, London. Improvements in and relating to channel torpedos. Complete specification. August 9

10922 C. Roth. See Class X.

10939 J. Boag, Glasgow. Improvements in the construction of blasting cartridges. August 11

11120 T. W. Newey, Birmingham. Improvements in matches and paper lighters. August 15

11286 J. Masters, London. Improvements in the manufacture of wax-matches. August 18

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

12561 H. S. Maxim. Manufacture of cartridges and explosive projectiles. August 3

12741 G. J. Smith. Method and material for rendering the coating of fuses incombustible. August 13

1887.

7603 G. S. Spencer. Detonating signal apparatus for railways. August 6

9209 L. G. Heusschen. A new explosive. July 30

XXII.—GENERAL ANALYTICAL CHEMISTRY.

APPLICATION.

10801 W. Devoll, Erdington. Improvements in apparatus for testing butter. August 6

UNCLASSIFIED.

APPLICATION.

10099 M. W. Hydes, Liverpool. Improvements in the treatment and utilisation of a hitherto waste, or nearly waste-product. July 19

Printed and Published by Emmott & Co., New Bridge Street, Strangeways, Manchester, for the Society of Chemical Industry.
London Office, for the Sale of Copies and Receipt of Subscriptions; 6, York Street, Covent Garden.

THE JOURNAL
OF THE
Society of Chemical Industry:
A MONTHLY RECORD
FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 9.—Vol. VI. SEPTEMBER 30, 1887. Non-Members 30/- per annum; Members 21/- per Set; Single Copies 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.

COUNCIL FOR YEAR ENDING JULY, 1888.

President: Prof. James Dewar, F.R.S.

Vice-Presidents:

Prof. F. Clowes, D.Sc.
Sir J. Neilson Cuthbertson.
David Howard.
Dr. Ferdinand Hurter.
Ivan Levinstein.
E. K. Muspratt.
Dr. W. H. Perkin, F.R.S.
Sir H. E. Roscoe, M.P., F.R.S.
John Spiller.
Prof. W. A Tilden, F.R.S.
John Williams.
Philip J. Worsley.

Ordinary Members of Council:

John Calderwood, F.R.S.E.
Eustace Carey.
R. Forbes Carpenter.
James Duncan.
Dr. John Evans, F.R.S.
S. H. Johnson.
John Pattinson.
B. S. Proctor.
F. J Rowan.
Dr. Edwd. Schunck, F.R.S.
T. W. Stuart.
Lewis T. Wright.

With Sixteen Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Ludwig Mood, 20, Avenue Road, Regent's Park, N.W.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

NOTICES.

Comment having been made on the delay in reprinting the numbers for January, 1882 and 1883, the Secretary begs to inform those whom it may concern, that the delay is due to the fact that up to the present not more than twenty orders for those numbers have been received. It is hoped that this notification may stimulate those who desire to complete their sets, to make early application with a view to expedite the consideration of the question of reprinting by the Council. Notice is also hereby given that the numbers for January and February, 1886, being exhausted, no orders for those copies, nor for complete sets of Vol. V., can be executed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January, 1882 and 1883, at the following prices:—January, 1882, 5s.; January, 1883, 2s. 6d. Members possessing odd copies of these numbers are particularly requested to communicate at once with Mr. Cresswell.

Authors of communications read before the Society or any of its Local Sections are requested to take notice that, under Bye-Law 43, they cannot receive the prescribed 50 copies of their communications unless they comply with the condition laid down in that Bye-Law—viz., that they give notice of their desire to receive such copies upon their manuscript before sending it to the Editor. Mention should also be made as to whether the Discussion is to be included in the reprint.

CHANGES OF ADDRESS.

Jno. Anderson, l/o Glengarnock; 56, Jamaica Street, Glasgow.

Dr. R. J. Atcherley, l/o Starch Green: 80, Elsham Road, Kensington, W. (for Journals); and 23, Bucklersbury, E.C.

R. W. Peregrine Birch, l/o Victoria Street; 2, Queen Anne's Gate, Westminster, S.W.

C. von Buch l/o Cavendish Place; 12, Buckingham Street, Strand, W.C.

F. G. Claudet, l/o Runcorn; 13, Townley Park Villas, Dulwich Rise, S.E.

F. J. H. Coutts, l/o Bolton; 216, Plymouth Grove, Manchester.

Spencer Dunn; Journals, etc., to 50, Upper Park Road, Haverstock Hill, N.W.

H. Frankland, l/o Eaglescliffe; Streonshalh House, The Crescent, Linthorpe, Middlesbrough.

Alex. Galt, l/o Hillhead; 9, Park Place, Rutherglen, Glasgow.

R. Gracey, l/o Nile Street; Tobacco Works, 70, Great George Street, Liverpool.

Agoew Griffith, l/o Liverpool; Daisy Mount, Blundell Sands, Liverpool.

Dr. F. von Heyden; Journals, etc., to Chemische Fabrik, Radebeul, bei Dresden, Saxony.

Wm. Jones, l/o New Broad Street; c/o Mr. Weils, 8, Derby Road, Burton-on-Trent.

J. Falconer King; Joornals, etc., to Russell Place, Edinburgh.

F. W. T. Krohn, l/o South Hampstead; 12, Brunswick Terrace, Newark-on-Trent.
Jas. L. Muspratt, l/o Flint; Kempton House, Rhyl, North Wales.
Jas. Muter; Journals, etc., to Oil Mills, Dunneedaw, Rangoon, Burmah.
B. Nickels, l/o St. Mary-at-Hill; 150, Holborn, London, E.C.
Thos. Parker, l/o Commercial Road; 6, Crawford Street, Wolverhampton.
A. G. Perkin, l/o Cheetham; 55, Victoria Crescent, Eccles, Manchester.
W. G. Reid, l/o Uphall; 2, Hailes Street, Edinburgh.
Jas. Richards, l/o Swinton; 340, Lower Broughton Road, Manchester.
Sir H. E. Roscoe, M.P., l/o Manchester; 10, Bramham Gardens, South Kensington, S.W.
C. Sevin, l/o Fenchurch Street; Morris Road, Chrisp Street, Poplar, E.
J. Fleming Stark, l/o Clapham; Bromborough Pool, near Birkenhead.
R. L. Taylor, l/o Higher Broughton; 37, Mayfield Road, Alexandra Park, Manchester.
G. Tunbridge, l/o Leicester; c/o W. H. Brown & Co., 54, Leadenhall Street, London, E.C.
G. Ward, of Leicester; Journals, etc., to c/o Richardson & Co., 10, Friar Lane, Leicester.

CHANGE OF ADDRESS REQUIRED.

G. J. Hamlen, l/o Muir Street, Silvertown, E.

Communications.

ON THE COMPOSITION OF SOME COKE-OVEN TARS OF GERMAN ORIGIN.

(Read before the British Association, Manchester, 1887.)

BY G. LUNGE,

Professor of Chemical Technology in the Federal Polytechnic School, Zurich.

THE composition of gas-tar—that is, that tar which is obtained as a "residual" in the manufacture of illuminating-gas, has been ascertained by many analyses, and is, moreover, thoroughly known from practical experience in the great industry of tar-distilling. But the case is quite different with the tar obtained as a by-product in the manufacture of coke, this industry having sprung up only within the last few years, apart from its isolated existence in the St. Etienne district. It is now placed beyond any doubt that the old mode of coke-making is very uneconomical, particularly when carried out in "bee-hive ovens," as it is almost universally in England, where the distillation gases freely escape and burn at the mouth of the oven, without as much as contributing to heat the ovens. But it is not sufficient to utilise the gases for heating purposes, as it has been done for many years past in the "Belgian" ovens and many other descriptions of coke-ovens, widely disseminated throughout Germany, France, and Belgium. Since the prejudice against the quality of the coke obtained in any other but bee-hive ovens has been thoroughly refuted by the practice of many of the foremost iron-smelters (which does not at all involve the *extinction* of that prejudice, no more than is the case with any other prejudice), it may be taken as an established fact that the only rational way of manufacturing coke is that in which all the products of the destructive distillation are utilised—tar and ammonia being condensed as liquids, and the gas being burned as fuel to carry on the process of distillation, without consuming any of the substance of the coke for that purpose.

It can be only a question of time when all the coke-works will be established on this basis. But it is self-evident that the enormous capital required for the reconstruction of all the old-fashioned coke-ovens now existing cannot be found all at once; nor is it even desirable that this reconstruction should take place with undue haste, for this would have a disastrous effect on the value of tar and ammonia, and completely disorganise all the industries in connection therewith. It can hardly be doubted that even the comparatively small quantity of those by-products which has hitherto come into trade has had a considerable share in the unprecedented fall in the value of those products, from which, fortunately, a reaction has taken place during the last few months. But it suffers no doubt that, as soon as any considerable and lasting rise of the prices of tar and ammonia should set in, there will be no lack of coke-works fitted up to meet the demand.

But it is not permissible to class coke-oven tar altogether with gas-tar without further enquiry. Undoubtedly an imperfect realisation of that fact has greatly contributed to check the expansion of the modern coke-manufacturing processes in England. This is owing to the circumstance that in this country the bee-hive coke-oven was pertinaciously regarded as the only one fit to turn out proper coke for iron-smelting, and that it was thought indispensable by most of those interested in this industry to connect any plant for recovering the by-products with the bee-hive oven, in the preconceived idea that the tar recovered from these must be of the same quality as that recovered elsewhere. On the other hand, in Germany coke-manufacturers had been familiar for a long time with closed coke-ovens, especially those on the Coppeé system, which are heated from without by means of burning the distillation gases, and it was a comparatively easy step to apply to those the Carvès process for taking out tar and ammonia, before burning the residual gas. It was soon found by practical trials that the quality of the tar obtained from Coppeé or Carvès ovens did not greatly differ from that obtained in the manufacture of coal-gas, and that the quantity of ammonia was about the same in both cases. English inventors jumped to the conclusion that these conditions must apply to coke-making generally, and that it was greatly preferable, in lieu of the Continental plan, to adapt some cheap recovery-plant to the ancient bee-hive ovens, both on account of the very much smaller outlay of capital, and of the assumed superiority of bee-hive coke, produced by internal combustion of part of the coal, to any coke produced by distilling the coal from without. But it soon turned out that the yield of ammonia from such modified bee-hive ovens (of which Jameson's are the most widely known type) was decidedly inferior; and matters were still worse with the tar, which could not by any means be employed in the same way as gas-tar, nor even for the production of illuminating and lubricating oils. This has been made very clear by the exceedingly thorough investigations of Mr. Watson Smith.* There were also other drawbacks connected with the working of the modified bee-hive ovens, and all this has evidently deterred the great majority of British coke-manufacturers from going into any improvements concerning the recovery of by-products. They preferred an expectant attitude, until the depression of prices made any further efforts in this direction altogether impracticable for the time being.

Fortunately in the meantime a few English coke-works had adopted the Carvès system (introduced into this country by Mr. H. Simon, of Manchester), and it was soon found that the tar produced by them is totally different from Jameson tar, and is comparable to gas-tar as to its yield of products useful in the manufacture of colouring matters. This tar has been repeatedly examined by Watson Smith.†

---

*J. Soc. Chem. Ind., 1883, pp. 403 and 499; Industries, 1886, p. 162.

†J. Soc. Chem. Ind., 1883, p. 500; 1885, p. 451.

Now the general principle of the Coppée ovens is so similar to that of the Carvès ovens, much difference as there exists in details, that the tar from both descriptions of ovens might be expected from the outset not to offer any essential chemical differences. Experience has proved this to be the case, as is evidenced by an analysis of tar from his ovens, quoted by Dr. Otto in *Stahl und Eisen*, 1884, p. 399. But this analysis is not authenicated by any name, and is much too little detailed in comparison with those instituted by Watson Smith. When meeting with this gap in the course of preparing the new edition of my "Coal Tar and Ammonia," I resolved to fill it up myself. Through the kindness of Dr. Otto I procured large average samples of two descriptions of tar—viz., one from the "Germania" pit near Dortmund, where there is a set of 50 Hoffmann-Otto ovens, and another from the "Hibernia and Shamrock" pit near Bochum, where there is a set of bee-hive coke-ovens, modified by a system totally different from those tried in England—viz., by making flues below the bottom, adding a Siemens recuperator, and heating the ovens entirely from without (by means of the bottom flues) without any internal combustion. These bee-hive ovens thus enter into the class of closed coke-ovens, and we shall not be surprised to find that the tar obtained from them is very similar to, although not identical with, that obtained from the Hoffmann-Otto ovens. The system in question has been patented by Dr. C. Otto in common with the Hibernia and Shamrock Coal Mining Company (Germ. Pat. No. 37,280) I shall refer to it, for the sake of briefness, as the "Hibernia" system.

Before entering into a description of the analytical investigation of those tars, I have to state that most of the practical laboratory work connected with it has been carried out in the most painstaking and conscientious way by my assistant, Dr. Jacob Schmid.

Such an investigation cannot be expected to yield useful results, unless somewhat large quantities are taken in hand. But in a scientific laboratory it is difficult to employ more than a few kilograms for each distillation. The results thus obtained will never exactly coincide with those obtained in manufacturing practice, but experience proves that they give a very good idea of the general quality of the tar. It would be most convenient to employ for such quantities distilling vessels made of metal, and I would, indeed, strongly recommend this for factory laboratories, all the more as it is thus easy to work upon very much larger quantities. But in scientific laboratories, where for more reasons than one it is out of the question to distil a hundredweight of tar or some such quantity, it will be always preferred to accurately observe the progress of the operation, and this it is only possible to do in glass retorts. Especially the dehydration of the tar, such as will be described further on, can be hardly carried out in any other way, whilst it is comparatively easily done in glass retorts. Watson Smith has also used such for his investigations.

My retorts were tubulated, holding about 5 litres, and were heated in a kind of sand-air bath—that is, in a suitably-shaped thin wrought-iron dish, the bottom of which was covered by a layer of sand, one centimetre thick. About half of the retort was within the dish, and the whole of it, down to the sand, and including the upper part of the neck, was wrapped round with wire gauze. The heating was done by a Fletcher's gas-stove, placed in a large flat pan, partially filled with sand. Hence, in case of an accident, the tar would have first run into the upper pan, forming the sand-air bath, and anything boiling over from this would have been caught in the lower pan.

The tubulure of the retort was fitted with a twice-perforated cork, holding a thermometer and a tube, drawn out into a capillary at the lower end, with the object of passing a minute current of air-bubbles through the liquid, in order to prevent bumping. This precaution, first introduced by Dittmar, and also employed by Watson Smith, was found to be very useful indeed; but it seems possible that the air current might carry away a minute quantity of benzene.

The retort was, during the first part of the operation, connected with a Liebig's condenser, so long as the distillate remained entirely liquid. When it began to partly solidify—that is, between 170° and 180°, the cooler was removed; and since now the last portions of water had been volatilised, and no more bumping was to be apprehended, the current of air was discontinued. The last of the water escaped between 140° and 170° with explosive violence.

The distillation of 2½ or 3 litres of tar took about 8 hours. It is decidedly advisable to carry it right through without any interruption, both because the heating-up, after the contents of the retort have been semi-solid or solid on cooling, is always an awkward operation, and because during the cooling-down and the heating-up a considerable quantity of substance passes over far below the proper boiling-points.

The distillates were collected in tared, narrow, graduated cylinders, and after cooling down they were measured and weighed. The fractions were made in the way to be stated below. But although, as a matter of course, every precaution was taken to keep the temperature as constant as possible, still, without any recognisable reason, the thermometer showed considerable oscillations, and sometimes went down 20° without any diminution in the rate of distillation.

It cannot be said that such assays are exact analytical operations. The fractions will differ to some extent, as the distillation proceeds more or less slowly. Each time, when substances are poured from one vessel into another, small losses are unavoidable, although in the case of the higher-boiling substances the vessels were rinsed with ether, which was subsequently evaporated. In washing and drying, in the case of the first distillates also by evaporation, small losses will occur, which become all the more important when the absolute quantity of substance is only slight.

If the tar had not been previously dehydrated, the work must begin with that operation, which is of great importance. It was easy enough with the "Germania" tar, which reached me almost completely dehydrated, but in the case of the "Hibernia" tar it could not be effected by several weeks' rest, even at a somewhat elevated temperature. It is not feasible to go as far as 100°, because then the tar would lose many valuable portions, especially as the operation takes so much time. Hence, the dehydration was performed in the retort itself, turning its neck upwards and connecting it with a cooler, inclined downwards, in order to collect any benzene escaping along with the water. The heating was continued in this manner to 60—70° for a full fortnight; every morning, before re-commencing, the water collected in the meantime on the surface was removed by a pipette. For all that some water remained behind, evidently in chemical combination with phenol, pyridine, etc., and this could only be removed by distillation.

Previous to the distillation, and after completing the dehydration as much as possible, the specific gravity of the tar was taken by pouring it warm into a 200cc.m. flask, and filling this up to the mark on cooling; the quantity left in the (previously tared) retort was taken as the basis of the subsequent calculations.

The fractions were made as follows:—

1.—Light oil, up to 170°.

2.—Middle oil, up to 230° (Carbolic oil).

3.—Creosote oil, up to 270°.

4.—Anthracene oil, up to the close of the distillation, which was continued as long as anything would come over; this explains why the pitch was extraordinarily hard.

The above fractions were treated in the following manner:—The *Light oil* was first agitated with caustic soda solution of specific gravity 1·1, and the contraction of volume was calculated as "phenols." The oil was then washed with water, with concentrated sulphuric acid, and again with water, and the total contraction was calculated as "loss by washing." The residual oil was distilled, and the fractions coming over up to 100° and 140° were separately collected. The distillate up to 140° was considered as "crude aniline benzol," and its degree of purity was examined by nitrification with the ordinary mixture of acids. The portion remaining behind at 140° was calculated as "heavy naphtha"; it must, of course, leave a good deal of residue on rectification, and this residue will practically go to the creosote oil; but, on the other hand, some heavy naphtha will come back from the "middle oil," and on the small scale it was impossible to say how far this would compensate for the residue left on rectifying. The small quantity of liquid also made it impossible to separate the "aniline benzol" into benzene, toluene and xylenes.

From the *Middle oil* and the *Creosote oil* a quantity of naphthalene crystallised on cooling. This was filtered through calico, strongly pressed, and calculated as "crude naphthalene." The liquid portion of the oil (making allowance for the mechanical loss in pressing) was treated with caustic soda solution, and the contraction of volume again set down as "phenols."

The *Anthracene oil*, after cooling, was filtered through calico, the crude anthracene was pressed cold, then spread out upon porous earthenware slabs, heated in an air bath to 30—40°, pressed while warm, and weighed. It was now analysed by the "Höchst" test (washing the anthraquinone with sulphuric acid), and the percentage of pure anthracene was thus established. But since commercial anthracene is generally sold at 33 to 40 per cent, three times the weight of the pure anthracene was deducted from that of the crude anthracene oils, in order to find that of the liquid anthracene oil. In actual work, probably the distillation would not be carried quite so far as in our case, or at any rate some of the liquid oil would be employed for softening the hard pitch, so that for practical purposes the quantity of liquid anthracene oil would be considerably less, and that of pitch correspondingly more than in our tests.

The *Pitch* was tested for its softening-point, by heating a piece of the size of a pea, stuck upon a wire, in an air bath alongside of a thermometer, until on pressing with the fingers, it proved to be distinctly plastic. The water bath did not suffice for this purpose. It was further tested for "carbon"—one of the most tedious parts of the work. For this purpose it was extracted alternately with boiling benzene and carbon disulphide; but it took many days toil, the solvents did not show any but a faint colour, and left no more residue when evaporated on a watch-glass. This operation must be carried out with the greatest caution, since otherwise fine particles of carbon will pass through the filter; for this reason Soxhlet's extracting apparatus, otherwise so convenient, could not be employed.*

The results were as follows:—

First Distillation.	A "Germania" tar: Hoffmann-Otto Ovens.		B "Hibernia" tar Otto's modified Beehive Ovens.	
Specific gravity at 15°	1·1198		1·1368	
	wght.	vol.	wght.	vol.
Light oil up to 170°: per cent...	6·55	7·43	1·88	5·21
Middle oil „ 230 „	10·54	10·16	14·14	13·97
Creosote oil „ 270 „	7·62	7·23	9·99	9·77
Anthracene oil.... „	14·35	—	22·65	—
Pitch .... „	30·55	—	43·41	—
Water .... „	trace	—	3·84	—
Loss .... „	0·39	—	1·09	—
	100·00	—	100·00	—

By working up the fractions we obtained:—

	A "Germania" tar.	B. "Hibernia" tar.
LIGHT OIL.		
Phenols..........................	3·30 % vol.	5·32 % vol.
Total loss on washing	18·42 „ „	33·05 „ „
Distillate from 78–100	8·11 „ „	trace.

PITCH.		
Softening point....................	165°	160°
Percentage of carbon	51·66	42·44

The *distillate from the washed light oil* up to 140° in the case of the "Germania" tar had the specific gravity = 0·869 at 15°; it could be nitrified without leaving any residue, and yielded 133 per cent. weight of nitro compounds of specific gravity 1·191. On distilling these yielded only 1·1 per cent. up to 190°, too small a quantity to be submitted again to the acid treatment. This distillate may, therefore, be set down entirely as "aniline-benzol," comprising within this term its percentage of xylenes. The portion distilling above 140° contained a good deal of naphthalene, against which should be set the naphtha coming back from the treatment of the middle oil. Since it was not possible to examine these small quantities of liquid more closely, I have set the whole down as "heavy naphtha"; but it cannot be expected to recover it all in the shape of commercial solvent or burning naphtha.

---

* An attempt to substitute for this tedious process a simple coking of the pitch did not yield any trustworthy results.

On rectifying the washed naphtha from the "Hibernia" light oil, the thermometer rapidly rose above 100°, then slowly up to 140°; a somewhat considerable proportion distilled only above 170°. On nitrification the distillate up to 140° yielded 129·6 per cent. weight of nitro compounds of specific gravity 1·188. On rectifying these, 2·47 per cent. of oil distilled between 110° and 190°, along with a little water. When submitting this oil once more to nitrification, nearly the whole of it remained unchanged. Hence, this "aniline-benzol" is not as pure as that from "Germania" tar; moreover, it contains very little benzene and principally toluene and xylenes; its value must be a good deal lower than that obtained from the "Germania" tar. Unfortunately the quantity of benzene from 2·7kilos. tar is too small to admit of any more extended investigation.

The described data will enable us to make the following statement concerning the commercial products to be got out of the two tars examined:—

	A		B	
	"Germania" tar per cent.		"Hibernia" tar per cent.	
Aniline-benzol	—	1·68	—	1·12
Heavy naphtha	—	3·61	—	2·06
Crude naphthalene from middle oil	4·54	—	1·09	—
Crude naphthalene from creosote oil	3·15	—	0·11	—
Crude naphthalene total	—	7·69	—	1·53
Crude phenols from light oil	0·25	—	0·28	—
" " " middle oil	1·56	—	1·90	—
" " " creosote oil	0·42	—	1·75	
" " total	—	2·23	—	6·93
Anthracene, calculated as 33 per cent.	—	1·59	—	0·72
Creosote oil for pickling timber	—	8·21	—	15·67
Filtered anthracene oil	—	42·76	—	21·93
Pitch (very hard)	—	30·55	—	43·11
Water	—	—	—	3·83
	—	98·38	—	97·21

Always bearing in mind that the above are only laboratory results, we may, nevertheless, draw the following conclusions.

The tar from Hoffmann-Otto's modified Coppeé ovens is at least equal in value to the best descriptions of gas tar. The "aniline-benzol" contains a good deal of real benzene, and is almost free from non-nitrifiable oils. There is an abundant quantity of heavy naphtha. That of the phenols and of naphthalene is normal, also that of anthracene (0·53 of pure anthracene in 100 tar). An essential difference between this kind of coke-tar and ordinary gas-tar, and that in favour of the former, consists only in the smaller proportion of creosote oil and of hard pitch, and a larger proportion of filtered anthracene oil, which is more and more employed for pickling timber and for lubricating purposes, and part of which can be usefully employed for working up with the hard pitch into soft pitch, varnishes, etc. All this is easily explained by the fact that the coke ovens in question work at a temperature at least as high as that of gas retorts, and that the coal remains in them for a longer space of time.

The "Hibernia" tar, produced in *outwardly heated* beehive ovens, and evidently at a lower temperature than the "Germania" tar, is not as valuable. It contains less aniline-benzol of inferior quality, less naphtha, and less anthracene. Especially remarkable is the very small quantity of naphthalene and the large proportion of phenols. It is also awkward to dehydrate. Still, this tar undoubtedly belongs to the same class as gas tar, and can be worked up exactly in the same manner. It is most sharply distinct from the Jameson tar, which must rather be classed with brown-coal tars, but does not, like these, yield a large quantity of good burning oils and solid paraffin.

Tar distillers still complain that even in Germany (where tars of the Jameson type are not produced), coke-oven tars are of unequal quality, and on the average yield less benzene than gas tar. But it should not be overlooked that gas tars are also nothing like uniform in quality, and there is some risk in that respect, even with the tar from one and the same gas-works, because they may make changes in the coal employed, and very frequently the quality of gas tar is deteriorated by the addition of bituminous shales in gas making. Such additions can never happen in coke making, and the coal used at a certain part must be always very nearly of the same quality. The differences in coke oven tars noticed up to the present will be partly caused by the unavoidable difference in the description of coals coked, and partly by the fact that the tar produced by different systems of coke ovens is not identical, as we have seen. Otherwise, there is no reason why, in the manufacture of coke, there should be any more irregularities than in the manufacture of coal-gas.

◆

ON THE COMPOSITION OF THE BLAST FURNACE TARS FROM THE GARTSHERRIE IRON WORKS.

(Read before the British Association, Manchester, 1887.)

BY WATSON SMITH, F.C.S., F.I.C.,

Lecturer in Chemical Technology in the Victoria University, etc.

The first examination of tar from blast furnace gases obtained by the condensing process patented by Messrs. Alexander & McCosh, and adopted in the Gartsherrie Iron Works of Messrs. Baird & Co., at Coatbridge, I undertook in 1883, and the results formed the subject of a paper read before the Society of Chemical Industry (Liverpool Section) in that year. The specific gravity of the tar was found to be 0·954. It was a tar lighter than water, and consequently would be subject to the immediate suspicion of tar distillers, all true gas tars of value for the aromatic constituents being slightly heavier than water. Subsequent examination showed that about 1 per cent. of paraffin wax could be extracted from the blast furnace tar, the crude Scotch shale oils yielding about 9 per cent of solid paraffin. The ordinary process of oxidising with chromic acid in glacial acetic acid solution failed entirely to discover for me any traces of anthracene in the higher boiling products from this tar, but I am convinced some anthracene is present, and shall submit the product to treatment by another process very shortly, so as first to effect separation of the preponderating paraffin. But the phenols presented a remarkable feature in this tar, on account of their abundance, as has been more recently confirmed by A. H. Allen and L. Archbutt ("Commercial Organic Analysis," vol. ii. 572 : Allen). However, my first experiments quantitatively aimed rather at a comparison of the amounts of crude phenol (carbolic acid) obtained by the commercial method of undersaturation with caustic soda of 18° Tw. It was then found that whilst—

(1.) Ordinary Lancashire gas retort tar oils, known as the carbolic oils, yield about 5 per cent. by volume of good crude phenol containing 65 per cent. (volume) of crystallisable phenol, that—

(2.) The blast furnace oils nearly corresponding to the above, gave by the same treatment no less than 17½ per cent. of phenols, containing, however, very little carbolic acid. The creosote oils gave 14·3 per cent. of phenols.

By a more recent trial (1885) I found that on exhaustive treatment with stronger caustic soda of the oils in the blast furnace tar of Gartsherrie analogous to the carbolic and creosote oils of ordinary coal tar, about 23 to 24 per cent. by volume of crude phenols could be extracted. Allen and Archbutt extracted from their samples of blast furnace tar oils even larger quantities.

It was also found that on extracting the same blast furnace oils with sulphuric acid of specific gravity 1·2, exhaustively, 11·09 per cent. by volume of crude basic constituents could be extracted.

K. E. Schulze (*Annalen*, 227, 143) propounded the theory that the aromatic coal-tar hydrocarbons are formed by the breaking up at higher temperatures of first-formed phenols into the elements of water and hydrocarbons, and this theory would, of course, pre-suppose the possible existence of certain *transition tars*, if we may so call them—*i.e.*, *transition* from the predominance of the paraffinoids to that of the benzenoid and allied products. Such a link of logical connection is supplied by the existence of a tar like that of the Gartsherrie iron furnaces, as well as those of certain coke ovens, which contain considerable quantities of benzenoid hydrocarbons and phenols. Schulze's theory being accepted as correct, we ought, moreover, to be able to find amongst the phenols in the transition tars those members most nearly corresponding to the hydrocarbons which predominate in what we may term *normal coal tar*, or perhaps, better, *gas tar*, as produced in gas retorts at the highest temperatures. In order to test this question an investigation was instituted in conjunction with Messrs. Coutts & Brothers (*J. Chem. Soc.* January, 1886; see also this Journal, 1885, p. 738) for the purpose of discovering which are the principal constituents of the blast furnace tar phenols. These were found to be ordinary phenol, the cresols (chiefly metacresol), xylenols (chiefly metaxylenol 1:3:4), pseudocumenol and the naphthols. It has been mentioned that an exhaustive extraction with dilute sulphuric acid yielded 11 per cent. by volume of basic constituents—*i.e.*, nitrogen bases. A more recent examination of these bases shows that aniline is present amongst them. The odour of the mixed bases is just that of the crude bases extracted from ordinary gas tar, reminding one of the pyridine and quinoline series. It was now of great interest to discover what hydrocarbons, especially of the aromatic series, are present in the blast furnace naphthas, since following Schulze's theory, and having detected the predominating presence of phenol, cresol and xylenol, more especially metaxylenol, also pseudocumenol and naphthol, we now ought to be able to find amongst the naphtha constituents the corresponding hydrocarbons.

In a recent investigation with the object of isolating the benzenoid and other aromatic hydrocarbons from the mixture, in which the paraffinoid hydrocarbons largely predominate, the hydrolytic method of Armstrong and Miller was made use of (*J. Chem. Soc.* 1884, 148). I desire to record here my opinion, after an extended experience of this method, that it is one of the simplest and at the same time most valuable solutions of a hitherto tedious and difficult problem that has been put into the hands of chemists for a long time, and Messrs. Armstrong and Miller deserve the thanks especially of technological chemists, whose vocations necessitate the frequent examinations of coal tars, naphthas and tar oils. The hydrocarbons thus isolated in the pure state are toluene, xylene containing 70 per cent. of metaxylene, pseudocumene and mesitylene. Also, I have identified the presence in the higher boiling oils of small quantities of naphthalene.

Benzene I have never been able to discover in the light naphthas, specimens of which have been kindly sent me from time to time by Mr. Andrew McCosh, of the Gartsherrie Works. However, I believe firmly that benzene is present in the crude gas used as fuel, and with the kind permission of the firm, I shall make this subject a further matter of experimental inquiry. The question, "Is bisulphide of carbon formed at the temperature at which such a low temperature tar as this is formed?" I shall try to answer at the same time, and it would doubtless be of practical interest to the gas industry.

It is certainly interesting, and so far confirmatory of Schulze's theory, that not only xylene and the other hydrocarbons corresponding to the aromatic phenols are present in the coal fed blast furnace fumes, but that the xylene is substantially of the same composition as that found in gas tar—*i.e.*, it contains about 70 per cent. of the meta-isomer. That this is the case was proved by means of Levinstein's method based on the reactions of Brückner and Jacobsen, as well as by the fact of the xylene obtained furnishing dyestuffs of the azo class. Thus, I have here a specimen of xylidine scarlet R. obtained from about 20cc. of the xylene of the blast furnace tar.

Mr. Hamilton, my assistant, whose valuable aid in this research I desire to acknowledge, will dye a piece of flannel with this scarlet, and I think I may assure you that no one has seen before a piece of fabric dyed with a colour derived from the waste gaseous products hitherto escaping in flames from coal-fed blast furnaces. Though I believe there is much truth in Schulze's theory of the formation of the aromatic hydrocarbons, I should be slow to ascribe this formation exclusively to the decomposition of the phenols, but would be most inclined to believe that the reaction is one running concurrently with several others. For example, the theories proposed by Berthelot, O. Jacobsen and Anschütz may all likewise, at least to some extent, hold good in the formation of the aromatic constituents of crude coal gas (see *Compt. Rend.* 62, 905; *Ber.* 1877, 853; *Ber.* 1878, 1215).

◆

A NEW APPARATUS FOR CONDENSING GASES BY CONTACT WITH LIQUIDS.

BY G. LUNGE.

The problem of condensing gases by contact with liquids is one which is presented in a very large variety of cases, only a few of which are enumerated here:—The condensation of hydrochloric acid, both when its manufacture is a principal object, and when it is only done to prevent pollution of the atmosphere; the condensation of sulphurous acid as a "noxious gas;" the manufacture of nitric acid, and its recovery from nitrous vapours by means of water and air; the condensation of ammonia in the shape of liquor ammonia; the absorption of chlorine in the manufacture of chloride of lime, of chlorates, of ferricyanides; the recovery of nitrous acid in the Gay-Lussac apparatus, and many others. We must also class herewith the drying of gases (chlorine, sulphur dioxide, atmospheric air, etc.) by means of sulphuric acid, as required for the Deacon chlorine process, and for the manufacture of sulphuric anhydride; the condensation of carbon disulphide by contact with cold water, and so forth.

For some of these processes special apparatus has been invented, according to the specific nature of the compounds to be treated, and with these we shall not occupy ourselves hereafter. We will confine our attention to that most numerous class of processes where, up to the present time, manufacturers in this country have almost exclusively employed the well-known coke tower, whilst continental manufacturers in many cases prefer a string of three-necked stoneware receivers or "tourilles." The latter are now generally supplemented by a small coke tower, mostly constructed from large stoneware pipes, and this combination, properly carried out, would seem to be the most favourable where the highest possible yield, along with the greatest possible concentration, are principally looked for, whilst the coke tower is found more suitable where the largest possible quantity of work is the primary object. Both kinds of plant have their advantages and their drawbacks. The tourilles system owes its success in producing very concentrated liquids to the systematical way in which the water or other condensing liquid travels from the further end of the set of receivers to the end nearest the furnace, always rising from the bottom of each receiver on to the top of the next receiver; the large cooling surface of the stoneware jars and pipes also comes into play here. On the other hand, the contact between the gas and the liquid takes place exclusively at the surface of the latter; the great bulk of the liquid participates but indirectly in the work of condensation, and some of the gas entering at the top of the receiver and leaving it at the opposite side does not come into contact with the condensing liquid. Hence a long string of receivers, often fifty and upwards, must be employed, and even then experience has proved that very perceptible quantities of condensable gases escape condensation, being carried along with the bulk of inert gases over the top of the liquid. Therefore, in the manufacture of hydrochloric acid the tourilles are now always supplemented by a small (sometimes even a large) coke column; and where the proportion of condensable gas in the total volume of gases is but small, as in the recovery of nitrous compounds in the manufacture of sulphuric acid, the tourilles system has been entirely superseded by the coke tower.

The manufacture of nitric acid by the ordinary method does not come under this head, for here the compound in question is itself a liquid, and the vapours need only be cooled down in order to yield the final product, therefore a smaller number of tourilles suffices, and they may be almost entirely superseded by stoneware worms, or the like.

The coke-tower is too well known to need any description or any specification of its merits. It is agreed that this apparatus has been instrumental in procuring the excellent and almost absolute condensation of the hydrochloric acid vapours in alkali works. But far superior as the coke tower is to the tourilles for taking out a small quantity of condensable gas from a great bulk of inert gases, it is not altogether beyond reproach. It has been found practically inefficient for washing sulphur dioxide out of furnace gases by means of water, nor is it a *perfect* condenser for the nitrous vapours in the Gay-Lussac process, even when made of very large size. Just these large dimensions, and the great attendant cost, form one of the drawbacks of the coke tower.

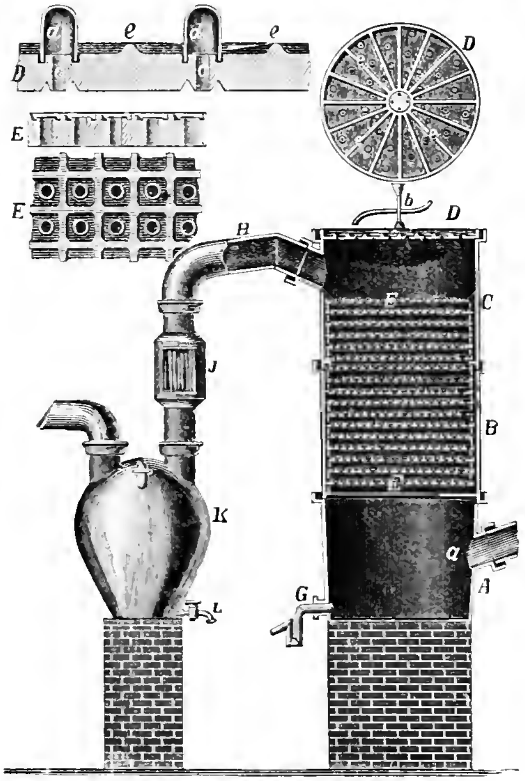
Let us consider in which manner a coke tower, say a hydrochloric acid condenser, acts. It is filled with large pieces of coke, about a foot long, at the bottom; then follow pieces of the size of a child's head, and at the top pieces of the size of an apple, but everything is kept out which passes through a sieve with 2in. meshes. The interstices between the pieces of coke thus must be pretty large, and very irregular. The coke is moistened by a shower of water, but this must not be too abundant, lest the acid should become too dilute, and it is therefore resolved into a number of drops, occupying a very small portion indeed of the channels left between the pieces of coke. These drops during their fall will therefore have but little action; almost the whole action of the tower depends upon the moisture covering the surface of the coke. Unless the latter is very well "packed," so that the gaseous current is constantly compelled to change its way, the tower acts very badly indeed; for naturally the gas ascends by preference in the widest and straightest channels, and just these are evidently least supplied with water in comparison to the air space. But even in a properly-packed tower the channels are comparatively very large, and, especially, very irregular; for this reason it is necessary to procure a very large condensing area, and to leave the gases in long contact with water, by constructing the towers of very large dimensions.

Of course all this has been very well known long ago, and attempts have not been wanting to diminish the size of condensing towers by substituting for coke regular pieces of perforated tiles, bundles of tubes, and similar objects. But not much has come of this; the remedy has never been a thorough one, and occasionally very expensive. Probably such apparatus are mostly in use only in such cases where coke is too rapidly destroyed by the agents at work within the condenser.

The just mentioned failures have deterred many from attacking the problem. Still I did not like to submit to coke towers as a finality, and I have tried to work out another system which should be founded on rational principles throughout. I have in this benefited by the co-operation of a manufacturer of chemical stoneware, Mr. Ludwig Rohrmann, of Krauschwitz, near Muskau, in Prussian Silesia, who has the command of most suitable material for acid and heat resisting stoneware, as well as great experience in the manufacture of chemical apparatus made from it, and untiring energy in overcoming the manifold difficulties which accompanied our first efforts. But success has not been wanting, and the apparatus which we have ultimately constructed has more than fulfilled the hopes I had entertained of it.

The following description and diagram will give an idea of the new apparatus, which I have styled the "Plate column," because its essential feature is in the perforated plates with which it is filled. It can be carried out in many shapes, and can be made of any suitable material, but so far it has only been made of that kind of stoneware which is the speciality ot Mr. Rohrmann. It is unnecessary to say that the material must offer the greatest possible resistance both to the action of acids and to changes of temperature, but it should also admit of a great deal of nicety in moulding every detail. For some purposes such apparatus might be made of metal, or even of wood lined with lead, especially when it is made of a larger size than can be well done with stoneware.

The plate column, in that shape which is now preferably made, consists of a number of earthenware cylinders of as large diameter as can be conveniently turned out. It is at present made 72 centimetres (say 2ft. 5in.) wide. The bottom is formed by a trough, A, with an outlet for the liquid, and an inlet for the gas, *a* (compare diagram). This bottom trough is surmounted by one or more cylinders, B, C, which contain the perforated plates, and at last by the top cylinder D, provided with an outlet for the gas, H, and an arrangement for spreading the condensing liquid. That liquid (in the majority of cases, water) is run from a store tank on to the cover of the column, and is spread out by means of the self-acting "acid-wheel" *b* all over the divisions, produced on the cover by the radial ledges, as seen on the plan D. The water runs off by the holes *c*, closed by the cups *d*, serving as hydraulic seals, and the bottom of the cover is so shaped that the liquid must drop out of each single hole without spreading along the under side of the plate. By this means the liquid is forced to drop quite regularly all over the area of the column, and to cover the whole surface of the uppermost of the plates EE.



Except the last-mentioned arrangement, there is nothing novel in the construction of the cover, indeed any other suitable means for spreading the liquid quite evenly all over the area of the column might be employed. But the peculiar feature of my apparatus appears in the plates EE. Each of these is covered with a network of small ledges, and in each of the squares thus formed there is a perforation, with a somewhat raised margin. The height of that margin is not quite as great as that of the ledges, hence there is always a layer of liquid, about ⅛in. deep in each of the squares, and as there is always more liquid dropping in, the excess is forced out through the perforations drop by drop. The plates are not identical in shape, but differ as to the position of the holes. To each perforation in any one plate there corresponds the point of union of the ledges in the plates above and below. Hence the liquid cannot drop straight through the holes in the following plates, but strikes the solid portion of the next plate, is scattered about, and is divided among the adjoining squares. This action is repeated from plate to plate. Thus the thin layer of liquid resting upon the plates and clinging to the holes is constantly renewed, and by the scattering about of the liquid another absorbing surface is created.

The gases and vapours rising within the column pass through the numerous holes of the lowermost plate, and are thus divided into a great number of fine jets. Immediately on issuing through the holes of this plate, they strike against the solid places in the next plate above, which correspond to the holes, and are thus divided and mixed again; and this process is repeated as many times as there are plates provided. Whilst the gases and vapours thus travel upwards in continuously renewed mixtures they come into the most intimate contract with the absorbing liquid, which they meet within the narrow holes on the plates and scattered all over in fine drops. By the incessant changes in the direction of the current, and the equally incessant renewal of the surface of the liquid, the most favourable conditions are produced for a mutual action of the gaseous and liquid substances. Owing to the principle of the apparatus, no false channels can exist, in which the gases or liquids would travel separately without coming into proper contact with each other.

This circumstance partly accounts for the enormous difference in condensing power between the "plate column" and a perfectly well constructed and packed coke tower, or any similar apparatus, fitted with pieces of pottery and the like. The liquid within a coke tower is never quite evenly distributed; there are always many places where it drops down a considerable height without meeting a piece of coke, and where, on the other hand, the gases find channels in which they can ascend without for some time getting mixed and coming into contact with liquid. Moreover, the individual gas channels are too wide, and the inner portion of the gaseous current does not enter into reaction with the absorbing liquid. This is unavoidable, because the interstices between the pieces of coke are quite irregular, and therefore the section of the tower must be made wide enough, and the pieces of coke large enough to secure a sufficiency of draught for the worst case. Nor, as experience has demonstrated, have any arrangements of pieces of pottery hitherto had a better effect than coke. Hence, coke towers must be made very wide and high, thus offering a long time and corresponding opportunities of mixing the gases and contact with liquid; and in this way the reaction is certainly very complete at the end. But this enormous enlargement of space can be avoided by the systematical way in which, in my new apparatus, the gaseous current is split up into upwards of a thousand very thin and exactly equal jets, which must continually alter their direction, and must, therefore, be thoroughly mixed every time they pass through a new plate. On their way they come into the most intimate contact with constantly and systematically renewed thin layers of liquid. The network of ledges prevents any unequal downward passage of the liquid, differently to the action of coke towers or of any other hitherto known form of similar apparatus. Perhaps a still more important difference is the following:—That there is a very thin and constantly renewed layer of liquid standing on each plate, and that the gases, in passing through the perforations of the plate, must frequently break through the drops of liquid. This seems to produce an action somewhat similar to the Coffey still, or other "rectifying" apparatus, and it may to a great extent explain that such an intense action takes place in so small a space.

Undoubtedly, with respect to the condensing action one of the most important conditions is this: that the gaseous current, holding small drops of liquid in suspension, should be exposed to very frequent *shocks* against solid surfaces. It is very well known that such shocks enormously assist the precipitation of extremely minute particles of liquid, existing in the shape of a mist, and not uniting into real drops under ordinary circumstances. This action is made use of in the Pelouze and Audouin process for purifying coal-gas from tar; it is at play in the vitriol chambers, and explains several phenomena unintelligible in other ways, as proved by Dr. Naef. It is also most certainly at work in the ordinary coke tower; but nowhere that I know of has it been so systematically and thoroughly brought about as in my apparatus, and this must go far towards explaining its great efficiency. It is unnecessary to say that these continuous shocks also greatly promote the mixture of the gases.

In one respect only the plate column is inferior to the tourilles system, and perhaps, even to the coke towers, namely, that the cooling action of the air has comparatively little scope. In the tourilles this action is very considerable; in the coke towers, with their thick stone walls, it cannot be anything like so complete; but the slow passage of the gases through these towers makes up for this to some extent. Whether the thin walls of the plate column do not compensate for the very much greater speed with which the gases pass through, I have no means of judging. In any case this cooling action is nothing like so important as the other considerations mentioned before, and it can be partly replaced by a good preliminary cooling of the gases before entering the columns. But for such cases where it is desirable that there should be good cooling in the columns themselves, I have constructed a special form of column, provided with an external water-cooling arrangement. This, of course, makes the apparatus much more complicated, and the simpler form of apparatus, as shown in the diagram, will be found sufficient for most purposes.

It is hardly necessary to say that several modifications of my apparatus have been arranged in order to adapt it to the special requirements of various technical operations; but I would not trouble the meeting with such details, confining myself to an explanation of the general principle. I may, however, be allowed to conclude with a short report of the work done by the first and necessarily imperfect form of apparatus at one of the best conducted German alkali works. They have there salt-cake furnaces, consisting of a combination of two pans with one roaster. The charge is 7cwt. of rock salt (98 per cent.) to each pan, or 14cwt. in all, and there are 7 charges made in 24 hours. The average proportion of HCl in the roaster-gas, as determined by a very large number of analyses, is 1·26 per cent. in one set, and 2·64 per cent. in another set (minimum 0·4 per cent., maximum 4·4 per cent.); the average proportion of HCl in the pan gases was 11·73 and 31·78 per cent. respectively (minimum 1·2, maximum 85·0 per cent.). The present condensing plant for the pans (we will leave the roaster gas out of consideration, as I have not tried any operations with it) consists in one case of 12 stone cisterns, with a water surface of 38·88 superficial metres; in the other case of 49 tourilles, with a water surface of 21·56 superficial metres. Although the air cooling in the latter case is far more thorough than in the former, the tourilles being connected with one another by U-tubes, a metre high, yet the cistern apparatus performs much better work, thus proving that the external cooling is nothing like so important as an efficient contact with water. The condensation in these cisterns or tourilles still being imperfect, the residual gases are carried into a coke tower, 100 feet high, which serves for the whole works. There was supplied to that works a set of five plate columns, consisting of 11 plates each, and possessing a total surface of only 1·36 square metres per column, or 6·8 square metres in all. A great deal of difficulty arose from this cause: that it proved practically impossible to equally divide the gases issuing from the bottom column among the four columns placed at a higher level. But just this circumstance led me to a brilliant demonstration of the efficiency of my system. I caused first two of the top columns to be cut off, and when it proved to be the case that there was still sufficient draught, and that the condensation was still good, a third column was cut off, so that all the gas from the pans passed only through the bottom column and *one* top column, thus applying a condensing surface of only 2·72 square metres, or about one-fifteenth of the surface of the water in the stone cisterns. But even then the acid came out between 23° and 36° Tw., the average strength being 32·4° at 15° C., and the quantity condensed amounted to 90 per cent. of that calculated from the salt charges. The trials were continued through 27 hours consecutively. Now, if it is considered that in this, the first attempt on a working scale, the apparatus still contained several imperfections, which could not possibly be remedied on the spot (the most important being a faulty system of feeding the columns with water, which caused great irregularities), it will be granted that the result obtained was most encouraging, and proved a great superiority of the plate columns over any other apparatus of similar size and cost. It cannot be doubted that, if it had been possible to apply half as many plates again, that is, about 33 plates in lieu of 22, in a consecutive set, and with a better system of water feeding, the condensation would have been as perfect as in all the cisterns or tourilles and the coke tower combined. But it was not feasible at the time to alter the apparatus in that manner, and only now it has become possible to turn it out in an improved form, guided by the experiences made in those preliminary trials. I hope to be able, at no distant time, to report the results obtained with the plate column in that improved form, as shown in the diagrams. But even as it stands now, I thought that a short report of a condensing apparatus, devised on more scientific principles than those previously existing, would not be unwelcome to those members of the Section who are interested in technological chemistry.

SACCHARINE: THE NEW SWEET PRODUCT FROM COAL-TAR.

(Read before the British Association, at Manchester, September 5, 1887.)

BY DR. CONSTANTIN FAHLBERG.

The subject which I am going to bring before you is one which may, perhaps, be known to many of you, at least, by name. In the first place, I think it well to give you a short history of this new and interesting compound, stating how I came to discover it, and what my principal work was during the period of nine years, in developing it for purposes of manufacture on a large scale.

When, in the year 1879, I became connected with the Johns Hopkins University of Baltimore, part of my work was to repeat the older experiments of Latchinow, Anna Wolkow, Remsen, Beckurts, and others, on the toluene sulphamides. I prepared first the toluene sulphamides, in order to study their oxidation products; some of them, the "para" and "meta" compounds, had previously been studied by others, but the "ortho" compound had not been investigated up to that time.

By oxidising pure orthotoluene sulphamide, I found that it yields a remarkably sweet compound, but the amount obtained by the process employed was so small, that it was hopeless to think of making the laboratory experiment fit for a manufacturing process. Not discouraged by this fact, I set to work to study other reactions, in order to get a better yield of the sweet body.

In the first place, the costly anhydrous or fuming sulphuric acid was not fit for yielding sufficient orthotoluene sulphonic acid: it was found that by treating toluene with anhydrous sulphuric acid the parasulphonic acid was the principal product formed. Experimenting with different strengths of acid, it was found that sulphuric acid of 66 Baumé answered the purpose best at low temperature, converting almost one-half of the toluene into the orthosulphonic acid.

The next step in the process was the treatment with phosphorus pentachloride—a reaction which cannot be carried out on a large scale. I therefore experimented with phosphorus trichloride, employing a current of chlorine gas, and found by this method of treatment that the action was less violent and more under control, but it gave the same results as when phosphorus pentachloride was employed. In order to manufacture phosphorus trichloride a new apparatus had to be devised, this compound not having been manufactured up to that time in sufficient quantities to warrant the hope of obtaining a continuous supply for my purpose.

The apparatus which I have devised for effecting this object is made of cast-iron, and the phosphorus used is the yellow and not the red modification; the apparatus being so constructed as to allow of continuous flow of phosphorus into it through a funnel. With this apparatus an unlimited quantity of the trichloride may be manufactured, the cost of production being comparatively small, whilst the purity of the article is very high.

In my laboratory work I made use of aqueous ammonia for transforming the orthosulphonic chloride into the amide, but I found that the water was very dangerous, changing the sulphonic chloride frequently back into the sulphonic acid and not into the amide as desired, and so rendering this step of the process very uncertain. To avoid this inverse reaction, water had to be excluded, and dry ammonia gas had to be used, which again required complicated apparatus and study of the conditions under which the reaction progressed most favourably.

My apparatus as now constructed, and the knowledge which I have gained by patient study of this part of the reaction, have so overcome this inverse reaction as to make the yield almost a theoretical one.

The oxidation of toluene orthosulphamide into saccharine requires great precaution, and it was found necessary to change very materially the work at this stage of the process from the laboratory method to that necessary for a manufacturing operation. In my previous work I had stated that toluene sulphamide yields on oxidation with potassium permanganate two products—namely, saccharine and orthosulphobenzoic acid. At that time I had assumed the reaction to take place with elimination, not of ammonia as a chemist would be inclined to suppose, but in that of nitrogen. Now I find that this reaction is an entirely different one; that neither ammonia nor nitrogen is formed, but that by oxidation, part of the amido group is changed into nitrates in the presence of potassium permanganate.

To check this formation, very dilute solutions have to be employed, and the subsequent evaporation becomes a very expensive operation.

A discovery which took place at this time helped me greatly to utilise the sulphobenzoic acid formed during the process, by transforming it into saccharine. This discovery consisted in the following reaction:—If a neutral salt of sulphobenzoic acid be treated with phosphorus pentachloride or with trichloride in a current of chlorine gas, the bichloride formed in this reaction yields, on treatment with ammonia, not as might be assumed, a diamid, but an ammonium salt of saccharine, from which saccharine can be easily separated, like from any other salt of it, by the addition of a mineral acid. The parasulphonic chloride, which forms a bulky mass, in order to carry through the operations to separate the orthosulphonic chloride, is now transformed in autoclaves under pressure, and by super heated steam into toluene and sulphuric and hydrochloric acids. The toluene is made use of again, and by this reaction almost all the substance started with is transformed finally into saccharine.

Works of such an extensive character as those at Salbke Westerhüsen, Germany, erected to supply the whole world with saccharine, require very large quantities of potassium permanganate and phosphorus, and to work economically it is necesssary to utilise the manganese hydroxide obtained as a by-product for reconversion into permanganate. It may also be necessary to utilise the phosphate residues for making phosphorus later on, if this material continues to be sold at its present high price, but I hope that the existing phosphorus manufacturers will be able to supply me for some time to come.

From the above statements you can easily conclude that there was much work to be done to put me in the position in which I am at present, to supply the world with a sufficient quantity of saccharine.

My previous publications on saccharine, although of an entirely theoretical value, had not been accurate enough in their statements, so as to leave no doubt about the constitution of saccharine. Remsen, Maumené, and others, had speculated on various formulæ for this new body. The former had assumed the formula to be  $C_6H_4\left<\begin{array}{l}COH\\SO_2\end{array}\right>N$; whereas Maumené had thought to find a similarity between saccharine and taurine, probably through his manipulative errors in the determination of sulphur.

For the formulæ of the salts of saccharine I had assumed the non-existence of the orthosulphaminebenzoic acid, and had thought the salts of saccharine corresponded to the formula belonging to sulphaminebenzoic acid. Later on the existence of orthosulphaminebenzoic acid was proved by Noyes, who had oxidised sulphamide with ferricyanide of potassium in an alkaline solution. It now became of the utmost importance to decide between the two formulæ assumed by Remsen and myself; and taking into consideration the work published by Noyes, whether the existence of orthosulphaminebenzoic acid was true or not, and which of the two formulæ really belonged to saccharine—namely,  $C_6H_4\left<\begin{array}{l}COH\\SO_2\end{array}\right>N$, or the formula suggested by me,  $C_6H_4\left<\begin{array}{l}CO\\SO_2\end{array}\right>NH$. I repeated the work of Noyes, and found that he was correct in all his statements. At present I have an investigation in progress, which will prove that the above orthosulphaminebenzoic acid of Noyes can also be made in a different way, and with a better yield, which reaction I will make known at a future time. The formulæ for the salts of saccharine, as assumed by me, were accordingly wrong in some respects, as it is impossible for two isomeric orthosulphaminebenzoic acids to exist. On re-examining my salts of saccharine I found them all to correspond to the formula  $C_6H_4\left<\begin{matrix}CO\\SO_2\end{matrix}\right>NM$, in which the hydrogen atom of the imide group is replaced by monad metals, or monad-organic radicles. The ethers which in my first attempts I found impossible to prepare, I have finally succeeded in forming, and these were greatly instrumental in helping me to prove the constitution of saccharine and its salts, without any doubt whatever. If any of these ethers be enclosed in a sealed tube in the presence of hydrochloric acid an alkylamine and sulphobenzoic acid are formed. I have proved, in one instance, the existence of ethylamine by the isonitrile reaction of Hofmann and the formation of the double salt of platinum chloride. This transformation proves beyond any doubt the constitution assumed by me, as given above, for saccharine and its salts, as well as for its ethers.

According to the above facts we must look upon saccharine as an inner-anhydride or benzoylorthosulphonic imide, which yields salts and ethers entirely different from the orthosulphaminebenzoic acid; in fact I have succeeded in transforming one into the other, and *vice versâ.*

If orthosulphaminebenzoic acid be heated, it changes into saccharine (*i.e.*, benzoylorthosulphonic imide) with the elimination of water; if, on the other hand, saccharine be subjected to a current of hydrochloric acid gas in the presence of alcohol, the ether of orthosulphaminebenzoic acid is formed, which also yields, on heating, saccharine, with the exception, that in this case not water but alcohol is eliminated. A further interesting reaction of the ether of saccharine, and not of orthosulphaminebenzoic acid, is this, that it forms by saponification with an alcoholic solution of potash a double potassium salt of ethylsulphaminebenzoic acid, having the formula $COOK—C_6H_4—SO_2N.KC_2H_5$. If this compound be treated with hydrochloric acid, or any mineral acid, the potassium is eliminated, and an isomeric compound of the ether of orthosulphaminebenzoic acid is formed, which I have designated as ethylsulphaminebenzoic acid, and which is isomeric with the above-stated ether of orthosulphaminebenzoic acid. I have an investigation in progress which will prove that these reactions hold good for all sulphimides; as, for instance, terephthalic and mesitylenic sulphimides, and other bodies of the same constitution.

Having mentioned the first difficulties which I met with, and having given you a short outline of the chemical side of the saccharine question (the material which has been of late so prominently before the public notice), I wish, at this stage of my paper, to call your attention to the uses of saccharine in the arts, in the household, and in medicine. I may say that there are at the present moment a number of manufacturers using saccharine already for the purposes of sweetening bread, cakes, champagne, lemonade, oils, essences and medicines of all kinds. Its sweetening power being three hundred times greater than that of sugar, you can imagine that it will serve for many purposes to which sugar cannot be applied, such as disguising the unpleasant taste of medicines, and be used in flavouring the food of patients to whom the use of sugar would be injurious.

One very important fact must be here pointed out with respect to saccharine, and that is, its non fermentable character, distinguishing it from the sweetening materials belonging to the carbohydrate class or sugar family proper; it is in no way altered by the action of yeast or other ferments, in the way that the carbohydrates are degraded, in fact, it rather acts in such a way as to prevent fermentation, so that saccharine retains its sweetening property under all conditions for an indefinite time.

In addition to the high sweetening power of saccharine, it has also antiseptic properties, which will make it useful in preserving articles of food, as I have frequently seen suggested in the newspapers; it is nothing more than a condiment or spice, and should never be tasted in the pure state, because taken in too large a quantity it will act upon the nerves in such a way as to paralyse the sense of taste, just as powerful music stuns or deadens the auditory nerves, or a very bright light acts upon the optic nerves.

I may inform you that almond and other breads are now to be had sweetened with saccharine, as well as champagne similarly sweetened, for diabetic patients and those suffering from fatty degeneration.

October (date to be fixed).—Opening Meeting: Address by the Chairman, Lewis T. Wright, Esq.

November.—C. Spackman, Esq., on "Portland Cement."

Notices of papers and communications for the meetings to be sent to the Local Secretary.

Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS AND MACHINERY.

Improvements in Chemical Fire Extinguishers. J. Haslam Tonge. Eng. Pat. 12,253, Sept. 27, 1886. 8d.

This invention relates to that class of apparatus wherein a bottle containing acid is placed in a solution of a carbonate, and broken when the occasion for use arises, and consists in providing means for readily charging and breaking the said bottle. The extinguisher case is provided at the top with a metallic nozzle closed by a

---

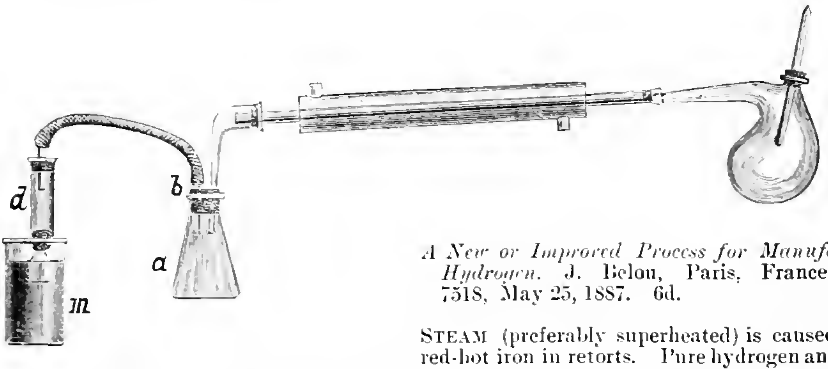
* Any of these specifications may be obtained by post, by remitting the cost price, *plus* postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.........	½d.
Above 8d., and not exceeding 1s. 6d...	1d.
,, 1s. 6d., ,, ,, 2s. 4d...	1½d.
,, 2s. 4d., ,, ,, 3s. 4d...	2d.

swivel lid or cover, the joint being made tight by an indiarubber ring. Attached to the underside of the nozzle is a wire cage containing the bottle of acid, and on the side of the extinguisher case is inserted a bar or plunger passing through a suitable stuffing box and provided with a convenient handle for driving it sharply against the bottle inside and effecting the breakage thereof. The same end may be attained by the use of an eccentric mounted on a spindle passing through a stuffing box in the case side. An outlet pipe delivers from the bottom of the casing and is of course controlled by a tap.—A. R. D.

Method for Distillation in an Indifferent Gas. P. Raikow. Chem. Zeit. **11**, 572.

The apparatus is filled with gas by means of the generator *d*, the cork of the retort being removed. This having been effected the cork is replaced and the distillation commenced. The evolution of gas is stopped by the pressure within the apparatus, but whenever this diminishes, the acid in the beaker rises in *d*, and the evolution of gas recommences.—A. G. G.



II.—FUEL, GAS AND LIGHT.

Improvements in the Manufacture of what are known as Mantles used in what is called Incandescent Gas Lighting. A Paget, Loughborough. Eng. Pat. 11,287, Sept. 4, 1886. 6d.

The patentee describes his improvements under four heads. 1. He temporarily strengthens the mantles (after due incineration and preparation) by immersion in a solution of some resinous, glutinous or farinaceous substance, 2. He attains the same end by immersion in some melted substance such as paraffin wax or beeswax, from which the mantles can be removed while hot. 3. He proceeds as under head 2, but allows the wax to cool with the mantle embedded in it. This entirely removes risk of breakage in transport. The surrounding substance left on the mantles by the above methods of treatment is easily burnt off previous to use. 4. To prevent the mantle from oscillating he drops upon its point of attachment to the suspending hook a drop of one of the well-known solutions of glass. The liquid is evaporated when the burner is lighted, and the residue, vitrified by the heat, cements the mantle to the suspending hook.—A. R. D.

Improvements in the Distillation of Tar, Oil, Resin, and Liquid Hydrocarbons in the Manufacture of Illuminating and Heating Gases therefrom, and in Apparatus for that Purpose. W. Burns, Leith. Eng. Pat. 14,958, Nov. 18, 1886. 8d.

This specification, which is unsuitable for abstraction, contains two sheets of drawings. The claims are:—1. "The particular mode of making gas from liquid hydrocarbons by distilling the said liquids in a double distilling retort and in mixing the vapours under hoods placed inside the retort and then decomposing the said vapours in a separate retort by passing them through red hot charcoal contained therein." 2. "The use of a fluted perforated pipe surrounded with charcoal inside the decomposing retort for distributing the hydrocarbon vapours and steam equally through the charcoal." 3. "The blowing of air through fluted and perforated pipes inside the decomposing retorts and surrounded by charcoal." 4. "The mixing of the fresh hydrocarbon liquids with distilled naphtha in the hydraulic main and then distilling the mixture in a low temperature still, placed on the top of the high temperature distilling retort, and then distilling the heavier portions in the high temperature still.—D. B.

A New or Improved Process for Manufacturing Pure Hydrogen. J. Belou, Paris, France. Eng. Pat. 7518, May 25, 1887. 6d.

Steam (preferably superheated) is caused to pass over red-hot iron in retorts. Pure hydrogen and oxide of iron are thus formed. The hydrogen passes on to a gasholder for use, and the oxide is reduced to metallic iron again by the introduction of charcoal dust. This latter operation generates so much heat that the retort is again immediately ready for decomposing steam. By using a number of retorts and carrying on the two processes of decomposition and revivification alternately, the production of hydrogen may be made continuous. Suitable provision must, of course, be made for the removal of the carbonic acid and carbonic oxide formed during the revivification.—A. R. D.

Improvements in Apparatus for Producing Gas or Vapour from Hydrocarbons, and for utilising Gas or Vapour for Lighting or Heating and for Igniting Gas. J. A. Marsh, Cleveland, U.S.A. Eng. Pat. 3418, March 5, 1887. 8d.

This specification is unsuited for useful abstraction. It has fifteen drawings explanatory of the patentee's twenty-one claims.—A. R. D.

Improvements in Regenerative Hydrocarbon Lamps or Lanterns. L. Chandor, St. Petersburg; and C. H. Nölting, London. Eng. Pat. 8790, June 18, 1887. 6d.

The lamp proper is contained within a casing provided with a double bottom. Air is admitted into the lower part of the casing, but cannot make its way direct to the lamp flame, as this is protected by a sheath. It therefore rises through a funnel kept hot by the escaping products of combustion, and then passes downwards by tubes to the hollow bottom of the casing, where suitable provision is made for causing it to circulate around the oil reservoir (which stands upon this case bottom) and then to pass through the upper part of the wick sheath to the flame. Glass chimneys are dispensed with, but the upper part of the lamp is provided with two sheet metal cowls, one within the other, whereby the draught can be regulated. Drawings accompany the specification.—A. R. D.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Improvements in Apparatus for Petroleum Distillation. Dingl. Polyt. J. **264**, 227—229.

THE usual forms of apparatus do not allow of a sufficient separation of the products by one distillation; the large quantity of raw naphtha to be operated upon in each still causes the lower layers to be overheated, and a continuous distillation necessitates a regular system of stills. O. K. Lenz, of Baku, has patented two distinct apparatus in which these objections are avoided. The one consists of a long four-sided boiler of thin iron or copper plate, on the two longest internal sides of which shallow gutters are horizontally fixed, along which the naphtha is made to flow from one end to the other, and thence on to the next lowest gutter, until the bottom of the boiler is reached. In this way only naphtha with a high boiling point runs out at the bottom of the last of a series of such apparatus, from each of which oil of certain special boiling points is obtained. To obtain constant regular results in working these boilers the inflow of raw naphtha must be accurately regulated, as also the heating. Lenz, by the use of two zinc rods fixed to one side of the boiler, passing out through stuffing boxes in the other side, and connected with levers which regulate the taps for the raw naphtha supply to the stills and the supply of naphtha residues to the fires, has rendered this apparatus entirely automatic.

The second apparatus consists of a long, four-sided metal box made up of two parts resting one above the other and bolted together. The lower one, which receives the raw naphtha for the distillation, is divided into numerous chambers by means of upright cross-walls projecting alternately from either side almost to the opposite side, so that the naphtha which flows in at the end furthest removed from the fires has to make a long zig-zag passage to the other end of the still. The upper vessel is likewise divided into a corresponding number of chambers; these, however, are not at all connected with each other, but each chamber is provided with a separate condensing apparatus. With this form of still a continuous fractional distillation can easily be carried on, raw naphtha entering at one end and the heavy residues being drawn off at the other. The still is fired by the gasoline vapours from the first compartment.—T. L. B.

Improvements in Apparatus for Washing or Treating Mineral Oils with Acids or Alkalis. A. C. Thomson, Edinburgh. Eng. Pat. 11,300, Sept. 6, 1886. 8d.

THE liquids which are to be agitated together are caused to flow through a series of turbines placed one above the other in a vertical cylinder. By another modification the process goes on in a horizontal or inclined cylinder divided into compartments and traversed by a central shaft, on which are fixed discs provided with bars or studs. As the shaft revolves these studs work in between corresponding bars or studs projecting from the partitions of the cylinder, and cause a thorough mixing of the contained liquids. The compartments communicate with each other, and the liquids travel from one end of the cylinder to the other.—A. R. D.

IV.—COLOURING MATTERS AND DYES.

On the Orange Azo-colours. Dr. Otto Mühlhäuser. Dingl. Polyt. J. **264**, 181—187 and 238—244.

THE paper opens with a short historical sketch of this class of colouring matters, ranging from the discovery of azo-benzene by Mitscherlich in 1834, and that of the diazo-bodies by Griess in 1858, to the investigation and manufacture of chrysoidine, and the tropœolins or oranges by Caro, Roussin, and Otto N. Witt in 1876—77. The author then proceeds to give details of the technical production of four of the most important simple members of this class of oranges, which are known under the names of orange I., or tropœolin OOO No. 1; orange II., or tropœolin OOO No. 2; orange R, and orange RR. The first operation in the manufacture of these bodies is the production of the amido-sulphonic acids of benzene, toluene, and xylene. In the case of the benzene and toluene compounds, the sulphates of aniline, or *o*- and *p*-toluidine, are decomposed by the aid of heat at 190—200°, according to the equation:

$$C_6H_5.NH_2.H_2SO_4=H_2O+C_6H_4.NH_2.(SO_3H).$$

An iron pan provided with cover, lead cooler, and stirrer, serves to mix the aniline and sulphuric acid together in; 49kilos. H_2SO_4 (66° Bé.) are placed in the pan, and 46·5 kilos. pure "aniline for blue" poured in a thin stream through the cooler into the acid, whilst well stirring for about twenty minutes. The cover is then removed and the acid aniline sulphate is equally divided among three shallow sheet-iron trays, 75cm. square and 25cm. deep, provided with slides to facilitate the drawing in and out of the oven. One of these trays at a time is then placed in an iron oven, 100cm. square and 50cm. high, which is built in a muffle-furnace so as to receive the heat at the bottom, at the two sides, and the end, the top being provided with an opening to allow the steam to escape. The temperature of the oven must be kept between 220—230°, for if raised above this, charring will ensue, and if allowed to fall below, there will be some of the sulphate left unconverted. In about three hours' time the reaction will be complete, and the cakes on the trays should, whilst still quite hot, show no sticky centres when broken up by an iron tool, but should be quite hard and brittle. The yield of crude sulphanilic acid averages 80kilos. from the above quantities. In the case of the toluidine sulphonation the proportions are 53·5 kilos. toluidine to 49kilos. H_2SO_4, but the temperature should not exceed 220°, and be maintained for from five to six hours. The xylidine sulphonic acid, which is used for the production of the orange RR, is obtained from *m*-xylidine by the action of fuming sulphuric acid. 175 kilos. 20 per cent. fuming acid are placed in an iron jacket, provided with stirring gear (20 revolutions per minute), and connected with both steam and cold water mains. Whilst well stirring, 50kilos. metaxylidine are slowly added, care being taken that the temperature of the mixture does not exceed 50°. The whole is then heated for four hours to 105—110°, until a sample thrown in water and made alkaline dissolves completely and gives no smell of xylidine. Hereupon the melt is blown by air pressure into a 3000-litre vat containing a solution of 64kilos. sodium sulphate in 1000 litres of water, the mixture made alkaline by the addition of about 120kilos. lime, raised to the boil by free steam and then say 500 litres of cold water added to cause the gypsum to crystallise. After being forced through a filter-press, the lime cakes are re-boiled, again put through the press, and the united filtrates evaporated to about 600 litres, then treated with about 5kilos. sodium carbonate to precipitate any lime still remaining in solution, when after another filtration the solution of sodium *m*-xylidinesulphonate is ready for further treatment. The crude sulphanilic acid is, after dissolving in the requisite amount of soda and water, boiling to remove aniline, and after filtration, also ready for subsequent operations.

The amount of sulphonic acid contained in these solutions is determined by normal nitrite solution, the reaction being

$$C_6H_4.NH_2(SO_3H)+NOOH=2H_2O+\overbrace{C_6H_4.N_2.SO_3}.$$

A solution containing say 2 per cent. of the acid, is acidified with excess of hydrochloric acid, and in the cold the nitrite solution slowly added until a sample dropped upon potassium iodide and starch paper gives the blue iodide of starch reaction. The normal nitrite contains 69grms. $NaNO_2$ per 100cc., 1cc. corresponding to 0·173grm. sulphanilic, 0·187 toluidinesulphonic, or 0·201 xylidinesulphonic acid. The nitrite solution may be standardised by the same reaction, using a $\frac{1}{10}$ normal sodium sulphanilate solution (19·5grms to 1000cc.), 1cc. of which equals 0·0069grm. $NaNO_2$.

In the actual manufacture of the colours, the amidosulphonic acids are by the action of nitrite of soda converted into diazo-sulphonic acids, and these then combined with either α-or β naphthol in alkaline solution, the quantities being so chosen as to correspond as exactly as possible to the theory as expressed in the following equations:—

$$\text{I.}\quad SO_3Na-R-NH_2+H_2SO_4+NaNO_2=Na_2SO_4+H_2O+\overline{R.N_2.SO_3}.$$

$$\text{II.}\quad \overline{R.N_2.SO_3}+C_{10}H_7.ONa=SO_3Na.R.N_2.C_{10}H_6.OH.$$

It is to be noted that excess of acid, *acid and nitrite*, or of naphthol, are prejudicial to a good result; it is advisable therefore to always have a small excess of diazo-compound and some 3 per cent. excess of alkali present.

Manufacture of Orange II., Tropæolin OOO No. II. $NaSO_3.C_6H_4.N:N\ C_{10}H_6.OH.(\beta)$. — 100kilos. sulphanilic acid are dissolved in an iron vessel in 400 litres of water containing 26kilos. solid caustic soda, and the solution boiled during twenty minutes till no smell of aniline is noticeable. The solution is passed through a six-chambered filter-press into a vat arranged upon a scale, the weight taken, the analysis made, and then run into the diazotising vat. This is provided with stirring gear, and should hold 2000 litres. The sulphanilic acid is then thrown down in a fine crystalline condition by the careful addition of 64kilos. H_2SO_4.(66° B.) whilst well stirring, and the mixture left over night to cool. Supposing the analysis gave 98·7kilos. sulphanilic acid, that would require 41·3kilos. nitrite of soda containing 95 per cent. $NaNO_2$ and 82·1kilos. β-naphthol. This naphthol is dissolved in 30kilos. caustic soda and 400 litres water, also being allowed to cool over-night. The next day it is run through a filter-press into the precipitating vat, which should hold 4000 litres and be provided with rapid stirrers. The stirrers of the vat containing the sulphanilic acid being put in motion, ice is added until the temperature of the mixture is reduced to 4°; the solution of 41·3kilos. $NaNO_2$ in 200 litres of water is then run in during say 10—15 minutes, until the starch papers show a slight excess of nitrite. If necessary more ice must be added, so that the temperature does not exceed 10°. After stirring for some five minutes or so longer, this diazo-benzene sulphonic acid solution is run carefully into the naphthol solution in the precipitating vat, which has been cooled with ice to 4°, stirring vigorously. This operation takes about forty minutes to accomplish, during which the temperature of the mixture must not exceed 12°. After stirring for about an hour the mass of golden yellow glistening needles is lowered into a montejus placed in the ground, forced through two 18-chambered filter-presses, and the mother-liquor well blown out of the cakes, which are then placed on zinc trays, cut up, and dried at 60—70° during three or five days. The yield of dry ground colour from the above quantities averages 200kilos. The mother-liquors are run to waste.

Manufacture of Orange I., Tropæolin OOO No. I. $NaSO_3.C_6H_4.N:N.C_{10}H_6OH(\alpha)$. — All the proportions and operations are exactly similar to those described for orange II., with the exception that in this case α-naphthol takes the place of the β-naphthol. Further, the mother-liquors are not run to waste, but are raised to the boil in a suitable vat, and the colour they contain salted out. When sufficient of this residual colour, say 10 lots, has collected, it is boiled up in about 2000 litres of water and again salted out, forming when dry one of the acid brown colours of commerce, *Acid Brown R.* The yield of orange I. averages 170kilos.

Manufacture of Orange R, $(NaSO_3)CH_3.C_6H_3.N:N.C_{10}H_6OH(\beta)$.—This colour, which is a combination of the diazo-sulphonic acids of ortho- and para-toluidine with β-naphthol, is made otherwise exactly in the manner described under orange II.

Manufacture of Orange RR, $(CH_3)_2SO_3Na.C_6H_2.N:N.C_{10}H_6OH(\beta)$ $[CH_3{:}CH_3 = 1{:}3]$. — In this case also the formation and combination of the diazo-*m*-xylidine sulphonic acid with β-naphthol takes place as described for orange II., but the resulting colour being gelatinous must be raised to the boil and then precipitated with strong brine before it can be filter-pressed. The yield from 50kilos. *m*-xylidine averages 155kilos.—T. L. B.

Manufacture of Acid Magenta. P. Schoop. Chem. Zeit. **11**, 572—573.

The sulphonation of rosaniline cannot be effected by means of ordinary H_2SO_4, even at high temperatures. A variety of sulphonating agents have been proposed for this purpose, but the only method at present in use consists in the employment of fuming sulphuric acid.

In performing the reaction the points to be taken account of are: (1) the concentration of the fuming sulphuric acid; (2) the temperature; (3) the length of time taken. As the quality of the product greatly depends upon the rapidity with which the operation is carried out, it is best to work with small quantities and to add the powdered rosaniline hydrochloride to the fuming acid, allowing the temperature to rise spontaneously. The operation is performed in a series of small pans, of about 15litres capacity, into each of which is put a mixture of 3½kilos. of 20 per cent. fuming sulphuric acid and 1kilo. of 40 per cent. acid. To each is then added, all at once, with vigorous stirring, 1kilo. of finely-ground magenta crystals, dried at 120—130 for 12 hours. The stirring is continued till all the magenta has dissolved: the temperature meanwhile quickly rises to 170° and the sulphonation is complete in about a minute. The cooled melt is diluted with water (1500 litres to 10 pans) and boiling milk of lime added till alkaline and colourless. The liquor is forced through a filter-press, and concentrated in a wooden vat by means of a steam coil. To the concentrated liquor is added sufficient hydrochloric acid to convert it into the acid salt and give it a bronzy appearance. The syrup is finally dried upon enamelled iron trays in a chamber at 100°. The press cakes are re-boiled, and the liquor used for diluting a second charge. When the sodium salt is required instead of the calcium salt, the concentrated filtrate is mixed with sufficient Na_2CO_3, filtered from $CaCO_3$, and the filtrate treated in the same way as above. 10kilos. of magenta give on an average about 20kilos. of acid magenta of ordinary strength. The strength of fuming acid required for the sulphonation varies very much with the quality of the magenta; thus maroon and cerise are far more easily sulphonated than crystallised magenta, and require an acid of lower value in SO_3 than given above.

—A. G. G.

On Rosindoles. E. Fischer and P. Wagner. Ber. **20**, 815—818.

By heating bodies of the indole series with benzoyl chloride, red colouring matters are formed of great similarity to rosaniline, and have hence been named rosindoles. The same compounds are also formed by oxidation of the benzylidene derivatives of the indoles. They probably stand in near relation to the triphenylmethane derivatives.

Dimethylrosindole $C_{25}H_{20}N_2$, probably

$$C_6H_5.C\begin{cases}C_9H_7.NH.\\C_9H_7N\end{cases}$$

—Obtained by heating equal weights of methylketole and benzoyl chloride with $ZnCl_2$ on the water-bath; or by oxidation of benzylidene-methylketole (from methylketole and benzaldehyde). The hydrochloride $C_{25}H_{20}N_2HCl$ forms small green-glistening crystals, sparingly soluble in water. It dyes silk and wool red. The base is precipitated from a cold solution of the salts in the form of a bright yellow amorphous powder, which by boiling with water darkens in colour and becomes crystalline; recrystallised from hot alcohol it forms orange-red prismatic crystals. It dissolves in alcoholic NaOH with a magenta-red colour, which disappears on addition of water. By zinc-dust and alcoholic NH_3 it is reduced to benzylidene-methylketole.—A. G. G.

Methylation of Indoles. E. Fischer and A. Steche. Ber. **20**, 818—820.

If methylketole (1 part) is heated with methyliodide (2½ parts) and a little methyl alcohol at 100° for 15 hours, a new base of the formula $C_{11}H_{13}N$ is obtained in nearly theoretical quantity. This compound is not an indole derivative, but is probably a derivative of quinoline (*i.e.*) dimethyldihydroquinoline. It boils at 243–244° at 746mm., is readily soluble in alcohol, ether, etc., very slightly in water. It does not redden a pine-wood shaving, is not affected by nitrous acid, and is a strong base. The sulphate crystallises from alcohol in small plates, the picrate in beautiful golden-yellow plates. Other indole derivatives behave with methyliodide in a similar manner, producing bases which are probably derivatives of quinoline. Ethyliodide also acts similarly.—A. G. G.

The Tartrazines, a New Series of Colouring Matters.

J. H. Ziegler and M. Locher. Ber. **20**, 834–840.

DIOXYTARTARIC ACID $\begin{array}{c}C(OH)_2.CO_2H\\ \vdots \\ C(OH)_2.CO_2H\end{array}$ is capable of forming a mono- and a diphenylhydrazide, which are termed by the authors mono- and diphenylizindioxytartaric acids. The di-sulphonic acid of the latter is the yellow dyestuff called tartrazine

Dioxytartaric-acid Monophenylhydrazide

$$\begin{array}{c}C_6H_5.N_2H : C.CO_2H\\ (OH)_2\dot{C}.CO_2H\end{array}$$

is formed at the ordinary temperature by mixing equal mols. of dioxytartaric acid and phenylhydrazine in dilute HCl solution, and separates on standing as a crystalline precipitate. It is readily soluble in hot alcohol and acetic acid, nearly insoluble in cold water, slightly in hot; it melts at about 218° C. It is decomposed by water or dilute acids only on long boiling. By sodium amalgam it is reduced to aniline and an amido acid. The sodium salt forms yellowish plates, the silver and barium salts yellow precipitates.

Dioxytartaric-acid Diphenylhydrazide $(C_6H_5N_2H)_2C_2(CO_2H)_2$. Obtained by heating the monophenylhydrazide (1 mol.) with a solution of phenylhydrazine hydrochloride (1 mol.), or directly from dioxytartaric acid (1 mol.) and phenylhydrazine (2 mols.). It is an orange-yellow crystalline powder, readily soluble in warm alcohol and acetic acid, very sparingly in water. It melts with decomposition above 200°. With alkalis it forms easily soluble neutral salts and sparingly soluble acid salts. The neutral Na and NH_4 salts crystallise in yellow plates, the acid salts in red needles. The *monoacetyl anhydride* $C_{18}H_{13}N_4O_4$ is formed by heating the acid with acetic anhydride. It crystallises on adding alcohol in glistening red needles which melt at 234°. It is insoluble in most solvents.

Dioxytartaric-acid Diphenylhydrazide Disulphonic acid (Tartrazine) $\begin{array}{c}C_6H_4(SO_3H).N_2H.C.CO_2H.\\ C_6H_4(SO_3H).N_2H.\dot{C}.CO_2H.\end{array}$ Prepared by dissolving 10 parts of phenylhydrazine-sulphonic acid in 40 parts of water with sufficient NaOH, and adding the solution to 5 parts of sodium dioxytartrate in 10cc. of water and 10cc. of hydrochloric acid. On warming the tartrazine separates out as an orange precipitate of the sodium salt. The yield amounts to 97 per cent. of the theoretical quantity. It dyes wool a beautiful greenish yellow, which is very fast to light.

—A. G. G.

A New Mono-sulphonic Acid of β-Naphthylamine.

Fr. Bayer and C. Daisberg. Ber. **20**, 1426–1435.

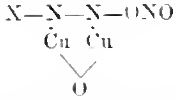
BY heating β-naphthylamine with three parts of ordinary H_2SO_4 at 100—105° C., a mixture of three isomeric mono-sulphonic acids (α, β and γ) is obtained, which differ considerably in their properties and colour reactions (Germ. Pats. 20,760, 22,547, and 29,054). Of these the β is also prepared by heating Schaeffer's β-naphthol-β-sulphonic acid with NH_3 under pressure. The γ-acid is the chief product when the sulphonation is carried out at 15—20° (Germ. Pat. 32,276). In addition to these the authors have found that by heating β-naphthylamine sulphate with much sulphuric acid at 150° or above, a fourth isomer is obtained. This δ-acid is also formed when either of the other three isomers is heated with sulphuric acid to this temperature. It is best prepared by adding 1 part of β-naphthylamine sulphate to 5 or 6 parts of ordinary H_2SO_4 at 150—160°, and keeping the mixture at this temperature for about 1½ hours. The hot solution is then at once poured into ice, allowed to stand some time and filtered. By repeatedly boiling the precipitate with water the δ-acid goes into solution and crystallises out again on cooling. It is obtained pure by conversion into the barium or sodium salt, which are sparingly soluble in cold water. The δ-sulphonic acid is sparingly soluble in hot water, nearly insoluble in cold, and crystallises in long silky needles ($+H_2O$). In their colour reactions with tetrazodiphenyl and tetrazoditolyl, the four isomers differ greatly. The α-acid gives with both these tetrazo compounds easily soluble yellow dyestuffs, very fugitive to light; the β- and γ-acids give with tetrazodiphenyl, yellowish red sparingly soluble products; with tetrazoditolyl the β-acid gives a fine red (benzopurpurin B), whilst the γ-acid gives an orange. The new δ-acid gives with tetrazodiphenyl an easily soluble yellowish-red dyestuff (δ-purpurin G), with tetrazoditolyl a splendid red (δ-purpurin 5B). The δ-acid also differs from the α-acid in the solubility of its sodium salt in alcohol, from the β-acid by the solubility of the free acid in boiling water, and from the γ-acid by the sparing solubility of its barium salt. By diazotisation and boiling with dilute H_2SO_4 it is converted into a δ-sulphonic acid of β-naphthol, which is identical with the β-naphthol-sulphonic acid F of L. Cassella & Co., obtained by heating naphthalene-α-disulphonic acid with alkalis. Conversely the β-naphthol δ-sulphonic acid prepared in the latter way can be converted into β-naphthylamin-δ-sulphonic acid by heating with NH_3 under pressure at 200°. The *barium salt* $[C_{10}H_6(NH_2)SO_3]_2Ba+4\frac{1}{2}H_2O$ crystallises in small plates, soluble in 400 parts of cold water. The *sodium salt* $C_{10}H_6(NH_2)SO_3Na+4H_2O$ forms small white needles, readily soluble in hot water and in hot alcohol, sparingly (1 in 70) in cold water.

—A. G. G.

Replacement of NH_2 by NO_2 in Aromatic Compounds.

T. Sandmeyer. Ber. **20**, 1491—1497.

THE conversion of aromatic amido-compounds into nitro-compounds can be effected by the action of precipitated cuprous oxide upon the nitrites of the diazo-compounds, possibly by intermediate formation of addition-products



$$\begin{array}{c}X—\overset{}{N}—\overset{}{N}—ONO\\ \dot{C}u\ \ \dot{C}u\\ \diagdown\ \diagup\\ O\end{array}$$

The amine is dissolved in exactly 2 mols. of dilute HNO_3 (or 1 mol. of dilute H_2SO_4, but not HCl), and to the mixture, cooled with ice, is added one half of a solution of 2 mols. of $NaNO_2$, the remainder being added when the diazotisation is complete. This solution of the diazo-nitrite is then added to the suspended cuprous oxide; nitrogen is evolved in the cold and the reaction is complete on standing for about an hour. As an example the conversion of aniline into nitrobenzene is performed as follows:—A cold solution of 20grms. of NaOH in 60cc. of water is added to a boiling solution of 50grms. of crystallised cupric sulphate (2 mols.) and 15grms. of ordinary glucose in 100cc. of water. As soon as all the cupric hydrate is converted into cuprous oxide the mixture is quickly cooled and the excess of NaOH neutralised with acetic acid. A solution of diazobenzene nitrite is prepared by adding 15grms. of $NaNO_2$ in 50cc of water to an iced solution of 9grms. of aniline in 50cc of water and 20grms. of nitric acid (sp. gr. 1·4). This is then slowly added to the cuprous oxide with cooling and allowed to stand for an hour till the evolution of nitrogen has ceased. The nitrobenzene is distilled off with steam and freed from phenol and nitrophenol by shaking with aqueous NaOH. The yield was 42 per cent. of the theoretical quantity. With *p*-bromaniline and β-naphthylamine the yield was still smaller. The product from the latter crystallised in yellow needles of melting point 78–79°, and had all the properties of the β-nitronaphthalene, as given by Lellmann and Remy.—A. G. G.

Indulines and Azophenines. O. N. Witt. Ber. **20**, 1538—1541.

AZOPHENINE $C_{30}H_{24}N_4$ is an intermediate product in the formation of induline. It is very readily prepared by heating a mixture of amidoazobenzene (2 parts), aniline hydrochloride (1 part), and aniline (4 parts) at 80—90° for 24 hours. The melt solidifies to a mass of azophenine crystals, which are separated by washing with alcohol (in which they are insoluble), and obtained pure by crystallisation from aniline or nitrobenzene. Ammonium chloride and *p*-phenylenediamine are constant by-products of the azophenine formation, a proof that a phenylation and reduction of the amido-azobenzene has taken place. If the melt containing the azophenine is further heated to 125—130 for some time, indulines are obtained. In the azophenine formation the amidoazobenzene can be replaced by other azo- and nitroso-compounds, such as phenylamidoazobenzene, azobenzene, chrysoidine, nitrosodimethylaniline, etc., without altering the product; but if toluidine is substituted for aniline, azotoline is obtained. This shows that azophenine is not a transformation product of amidoazobenzene, but is simply an oxidation product of aniline. A convenient method for the preparation of azophenine and its homologues consists in dissolving nitrosodimethylaniline with excess of aniline (or homologues) in acetic acid and warming slowly to 80°. The liquid solidifies to a crystalline magma of the corresponding azophenine, the mother-liquor containing dimethyl-*p*-phenylenediamine. Azophenine itself forms unstable salts of a violet colour; it does not appear to have any replaceable hydrogen attached to N, for it cannot be acetylated. By heating alone to 360° it is converted into aniline, and *fluorindine*, a splendid blue crystalline dyestuff, whose solutions exhibit a fine red fluorescence and a remarkable absorption spectrum. Azophenine is reduced by tin and HCl to aniline, and the sparingly soluble hydrochloride of a new base; the latter when set free by alkalis is rapidly oxidised by the air, forming phenylcarbamine and a red base whose salts are of an indigo-blue colour. The indulines, like azophenine, are probably condensation products of aniline formed by removal of hydrogen. If ordinary induline is distilled with CaO, the distillate consists chiefly of carbazol; this would seem to indicate that induline belongs to the class of diphenyl derivatives.—A. G. G.

Roshydrazine and a New Class of Colouring Matters. J. H. Ziegler. Ber. **20**, 1557—1558.

THE colour- and leuco-bases of triphenylmethane, when diazotised and treated with $SnCl_2$, are readily converted into hydrazines. For example: Rosaniline (5grms.) is dissolved in 30cc. of hydrochloric acid and 70cc. of water, and the iced solution is diazotised by adding 3½grms. of $NaNO_2$ in 10cc. of water. On mixing the solution of the diazo-compound with a well cooled solution of 12grms. of tin in 30cc. of hydrochloric acid, the *roshydrazine hydrochloride* separates out in green-shimmering crystals. The body is easily soluble in water, nearly insoluble in hydrochloric acid. Its solution has a bluer shade than rosaniline; it is a strong colouring-matter, and dyes tannined cotton a deep brownish-red. Like other hydrazines it reduces Fehling's solution and forms condensation-products with aldehydes and ketones. The latter compounds are sparingly soluble dyestuffs: thus acetone, aldehyde, pyruvic acid, benzophenone, etc., give reddish to bluish violet colours; acetoacetic ether and benzaldehyde give blues; whilst glucose gives a greyish-blue. Benzaldehyde sulphonic acid yields a blue soluble in water. These condensation-products can also be formed upon the fibre. The reduction of the diazo-compound of acid-magenta gives rise to easily soluble sulphonic acids of roshydrazine, the condensation products of which are soluble colouring matters. Saffranine, when treated in the same way, does not give a hydrazine, but evolves nitrogen.—A. G. G.

Manufacture of α-Naphthylamine. O. N. Witt. Chem. Ind. **10**, 215—220.

ALTHOUGH chemically the preparation of α naphthylamine is quite analogous to that of aniline, the difference in the physical properties necessitates great modifications in the practical details of the process. The purity of the naphthalene used is of great importance. It should melt exactly at 79° C., and boil constantly at 216°—217° C. A small piece exposed to the air on a glass plate should evaporate in a few days without leaving any residue, and remain white to the last. No red colour should be produced by heating 1grm. with pure concentrated H_2SO_4 to 170—200°. If the naphthalene fulfils all these conditions, it is suitable for the preparation of naphthylamine.

The nitration of naphthalene is not an easy operation, for the nitro-derivative is attacked by warm nitric acid almost as easily as naphthalene itself, so that when working in an ordinary manner a mixture is obtained of unaltered naphthalene, nitro-naphthalene, and dinitronaphthalene. To avoid this difficulty as much as possible the operation is performed as follows:—In a cast-iron jacketed shallow cylinder provided with an agitator is put a mixture of 200kilos. of nitric acid (40° B.), 200 kilos. of ordinary sulphuric acid, and 600kilos. of the spent acid from a preceding operation. 250kilos. of naphthalene, ground to a fine meal, is slowly sprinkled in through a sieve keeping the temperature at 45—50° by regulating the stream of cold water flowing through the jacket. At this temperature the nitration takes place steadily, and with the above quantities is completed in the course of a day. The contents of the vessel are now run out into lead-lined troughs, and allowed to cool, when the spent acid can be drawn off from the solid cake of nitro-naphthalene. The latter is freed from acid by boiling with water, and finally granulated by running in cold water whilst stirring. The product should then form light yellow granules and give off no naphthalene on boiling with water. If required for sale it is crystallised; this is best effected by melting on a water-bath and adding one-tenth its weight of xylene or solvent naphtha. The mixture keeps fluid for a long time, and can be filtered and dried over $CaCl_2$; when left to itself it slowly crystallises, and the crystals can be freed from hydrocarbon and impure nitro-naphthalene by hydraulic pressure.

The reduction apparatus is very similar to that employed for aniline, but simpler, as no cohobator or condenser are required.

The reduction is performed with iron and a little HCl in the same way as with nitro-benzene; 800kilos. of iron borings, 40kilos. of hydrochloric acid and some water are put into the still agitated and warmed; 600 kilos. of granulated nitro-naphthalene are slowly added; the reaction is tolerably vigorous, and is so regulated that the temperature of the mixture keeps at about 50°. When all the nitro-naphthalene has been added the temperature is maintained for 6 or 8 hours by blowing in steam. When nitro-naphthalene can no longer be detected, milk of lime (about 50kilos. of CaO) is added, the mixture stirred vigorously and emptied out. Since naphthylamine is only slightly volatile with steam, it cannot be isolated in the same way as aniline, but the mass has to be submitted to dry distillation.
